From this remark it must not be understood that dry-shining can be done "right off the reel" by the novice, for, like everything else in polishing, it requires attention and a certain degree of skill, though not by any means to the same extent as spiriting off. It is not, however, like glazing, in some degree a substitute for that difficult process; and those who may think that they can get a high degree of finish on their work by means of dry-shining it may as well give up the illusion at once. If a really good finish is wanted, French polish, as it is ordinarily understood by members of the craft, must be done, for there is no efficient substitute with which a like result can be got. What, then, is dry-shining, and what is it used for?

Well, let the latter part of the question be answered first. It is useful for finishing inside work—such as the insides of boxes, drawers, cabinets, and interior parts generally—and is often seen on the fronts of drawers and trays enclosed in a wardrobe. In fact, it can be used in any position where a high degree of finish is not necessary or customary. The chief advantages in connection with it are that it can be done expeditiously, and therefore cheaply; that it sufficiently closes the grain of the wood to prevent dust getting in and clogging it up; and lastly, it gives a degree of finish which wood left "in the white" or altogether unpolished does not possess.

Now, to answer the question as to what dry-shining is, shall we add how it is done? Roughly speaking, it is the nearest approach to varnishing by means of a rubber, instead of a brush, that polishers practise with ordinary French polish. The wood, if it may be so said, is varnished with this, applied by means of the polisher's special appliance—the rubber. In practice, dry-shining is done almost as bodying in, or, to be more accurate, is bodied-in work finished as in glazing, but with French polish used instead of glaze.

The wood is bodied in without any preparatory filling, but otherwise precisely in the ordinary manner, as directed in a previous article. It is not, however, customary to take such precautions to get up a good body as was then recommended; in fact, bodying up for dry-shining is somewhat of a misnomer as the work is generally done. A better idea would almost be conveyed by saying that the wood is wiped over with the polish rubber, as not much trouble is usually taken to do more than get the preliminary body worked on. Of course, something in this respect depends on the position of the part and the class of work being "dry-shined," for there is no reason why the first body should not be allowed to sink, and then be re-bodied if necessary. To do much bodying in, however, would make the amount of work almost equal to that involved by ordinary French polishing, so that ordinarily dry-shining is practised as stated. When a superior finish is wanted, there is, of course, no objection to French polishing the parts which have been mentioned as suitable for dry-shining. Beyond the fact that this answers well enough, there is no practical reason, except that it is less costly, why it is adopted.

When the bodying up, then, has been done to the satisfaction of the polisher, it only remains to finish it. To do this, the rubber is charged with French polish: if anything, rather more fully than was recommended for bodying, and instead of being rubbed all over the wood in any direction, is wiped over in the direction of the grain from end to end of the piece, very much in the same manner as was mentioned in connection with glazing. The rubber may be moved backwards and forwards till dry, if desired, but a better way under ordinary circumstances is to let the polish deposited by each rub dry before going over the same place again. When using the rubber in finishing, it should have no oil; and, if the former of these two methods is done, it will be difficult to prevent the polish dragging, so that the easier course may as well be adopted.

This method of finishing work—viz., by dry-shining, which, by the way, is a technical expression seldom heard outside the workshop, as to the general public it is included in the general term of French polishing—is the crudest and simplest way in which a gloss can be got on the surface of wood by means of a thin varnish of shellac and methylated spirit. It must not be mistaken for varnishing, as this process is ordinarily understood, for it is distinctly a French polishing one.

## SOMETHING ABOUT THE "PUFFS" OF A LOCOMOTIVE.

BY P. H. D.

THERE must be something strangely attractive and wonderful about the "puffs or beats of the exhaust" of a locomotive, as they are the first to attract the attention of a speechless baby when taken by rail, and it generally shows its joy and surprise by smiling, and trying to reach them with its tiny hand. But I am sorry to say that, as the majority of these children grow up, their curiosity gradually subsides, though to anyone interested there is a great deal to be learnt therefrom. How many of the thousands of passengers who daily make use of the railways in and about London, if asked, "How many puffs does a locomotive emit when travelling a given distance?" could give even a suitable answer, by which the problem could be solved correctly? Yet, while waiting on the platforms, each person sees on an average twenty trains daily, entering and departing, and no curiosity seems to be aroused in their minds, which I can only account for by the very familiarity of the object. Probably, a few remarks will not be uninteresting to those readers who are fond of railways, and all things appertaining to them.

I will first endeavour to answer the question in the foregoing paragraph. The number of "exhausts" emitted by an engine are proportionate to the number of revolutions of the driving-wheels, and not, as some people suppose, more numerous when running at a greater speed than when covering the same distance slowly—that is to say, the same engine would exhaust the same number of times in travelling twenty miles, whether it moved slowly or quickly. Of course, the quicker the speed the quicker the exhaust, but then the engine gets over the ground at a proportionately increased speed.

The number of "exhausts" emitted by an ordinary locomotive is four for every revolution of the driving-wheel, and these can be easily counted when an engine is leaving a station with a good heavy load, as it moves slowly, and the "puffs" are distinct, and take place as the crank-pin passes the right, upper, left, and lower centres. As an example, I will take a Midland express engine, and work out the number of "puffs" it emits in going a given distance. We will take the run from London (St. Pancras) to Leicester, 100 miles (99¼ miles is the correct distance, but for simplicity we will take the former figure). The diameter of the driving-wheel is about 7 feet: this, multiplied by 3·1415, will give us the circumference, which comes to nearly 22 ft., which we will consider as correct. Now, if we divide 100 miles (the distance traversed) by 22 ft. (the circumference of driving-wheel), we shall get the number of revolutions of the main-wheel in running this distance. There are 528,000 ft. in 100 miles: this, divided by 22, gives 24,000 as the number of revolutions. Now, as there are four "puffs" to each revolution, 24,000 by 4 will give us the number of "puffs" in running 100 miles, which amounts to 96,000. The express trains

are allowed a little over two hours to do this journey, but I have a record before me which gives the details of a fine run by the Scotch express from Leicester to London on April 28th, in which the whole journey was accomplished in 1 hour and 46 minutes, or at an average rate of nearly 57 miles an hour. This was an altogether exceptional run. So we will allow two hours for the journey, when we shall find that the number of "puffs" per hour is 48,000, or an average of 800 per minute.

Edinburgh is 400 miles from King's Cross, so that an engine with the same size of driving-wheel as just mentioned would give a grand total of 384,000 "puffs" in accomplishing that distance.

There are, however, some express engines, termed "compounds," which, with the same diameter of driving-wheel as above-mentioned, would only give one-half the number of "puffs" in going the same distance. Such engines are to be met with on the North Eastern, but the principal railway employing them is the London and North Western, on which there are a great number in general use. The reason the number of "puffs" is diminished is that the steam, after having done its work in the high-pressure cylinder or cylinders, instead of blowing out into the air, passes into a larger one, and the steam is only allowed to escape into the air after having done its work there, so there are only the two exhausts from this one cylinder, instead of four from two cylinders, as in the preceding cases.

The size of driving-wheels, as a great many readers will know, depends on the kind of traffic to be dealt with. If the engines are to start quickly and pull a good load, as in the suburban passenger traffic at certain times of the day, the wheels are reduced in size, and often two or more are coupled together, till the extreme is found in the goods engines, which have the smallest wheels, and generally six of them are coupled together, as they have to draw heavy loads at a medium pace.

The exhaust is also a good indicator of the setting of the valves. If the "puffs" come regularly and clearly, then we know that the valves are correct; on the contrary, should the "puffs" be irregular, then the presumption is that the valves are wrong in some way, and the defect should be corrected.

There are very few persons who cannot tell when a locomotive is pulling a good load, and still very few would be able to say on what they base their opinion. In most of the cases it would be from the great noise made by the exhaust steam escaping in such quantities from the chimney.

Another peculiarity is that the exhaust steam issuing from the chimney emits quite different sounds on the several lines, which is accounted for by the difference in the tastes and ideas of the various locomotive engineers of the different lines. If you were to listen attentively and frequently, you could very easily distinguish some of the railways by this means, as the variation of sound in the exhaust is very marked. Again, in others, this difference is very slight. A great many engineers would be able to tell to what line a locomotive belonged, simply by the sound of the exhaust alone, without seeing it.

I hope these few remarks will be serviceable to someone among the many readers of this paper, as I think the study of the subject will be interesting. Like many other things, much may be learnt from it if properly investigated.

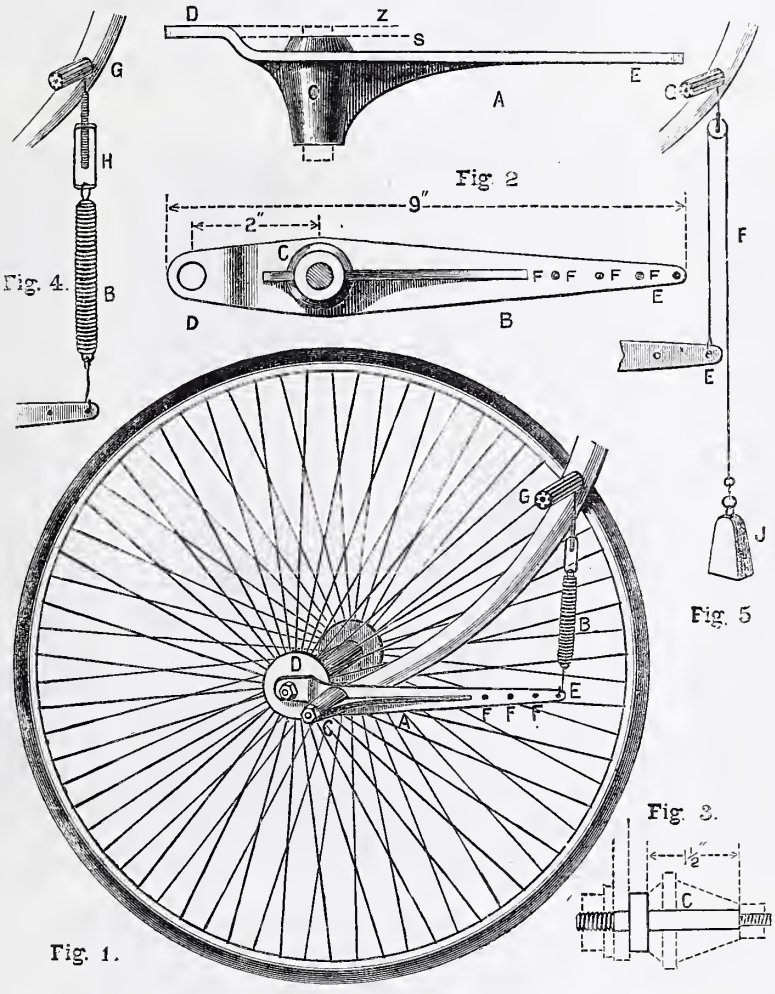

**Fig. 1.—Bicycle Wheel fitted with Anti-Vibrator. Fig. 2.—Lever—A, Side View; B, Plan. Fig. 3.—Form of Spindle. Fig. 4.—Attachment of Spring to Lever and Foot-Rest. Fig. 5.—Diagram showing how to determine Tension of Spring.**

## A SIMPLE ANTI-VIBRATOR FOR BICYCLES.

BY CYCLOPS.

Even though it may be late in the cycling season, there may be many readers of this paper who will be thinking of "going in" for a machine, or who, having an old one, feel inclined for a change.

One of the first questions which will occupy their minds is what kind of a machine they intend to ride.

Those whose pockets are minus the useful metal will look with envy on the purchasers of cushion or pneumatic-tired machines, and many of these have been in use this season.

The tire question is the all-absorbing subject of talk and discussion in cycling circles, and no doubt most of the machines sold this year will be fitted with one or the other of these luxuriant appliances.

To the attention of those readers of Work who are not in a position to purchase new machines this paper is especially directed, and the anti-vibrator which the writer is about to describe is one which may go a long way towards making up for the want of a cushioned tire.

As will be seen from a glance at Fig. 1, the appliance consists essentially of a lever, A, and a spring, B, which so act on the wheel and frame as to intercept any vibration which may be caused by rough roads.

The spindle carrying the long bearing, C, of the lever, A, is attached to the end of the fork by a nut and washer in the same manner as the wheel spindle was attached to it. The wheel spindle is attached to the end of the lever by its own nuts and washers in the same way as it was attached to the fork ends.

The lever, A, moves on the long bearing, C, and the spring, B, keeps it in place until some obstacle is encountered, when the wheel, in jumping over it, forces down the end, E, of the lever, and expands the spring, B, which thus takes the vibration which would otherwise be conveyed by the rigid fork to the rider.

A reference to A, in Fig. 2, will show the form of the lever, which will be best made of malleable iron. The pattern for casting will be exactly of the form of the lever itself, except it is intended to turn out the bearing, C, to fit its spindle, in which case the hole through the boss, C, being small, need not be made by prints, but be drilled from the solid. It will, of course, be understood that all parts are in duplicate, there being one for each side of the wheel. The side view of the lever is shown at B, in Fig. 2; the holes shown at F, F, F, F, are for the hook end of the spring, and can be bored in the lever after casting. The width between the lines S and Z, in A, Fig. 2, will have to be the same as the thickness of the spindle collar and fork-end. This will be obvious after consideration. By making both top and bottom half of the lever of the same form, only one pattern will be required for the two, which will be an advantage.

The form of the spindle on which the long bearing oscillates is shown at Fig. 3. The spindle should be made of forged steel, turned up and screwed to fit its nuts and the long bearing.

The dotted lines in Fig. 3 show the nuts, washers, fork-end, and long bearing.

The spring, B, is attached to the lever, A, and the foot-rest, G, by hooks, as shown in

Fig. 4, the screw joint, H, being to regulate the tension of the spring. These hooks should be closed when the spring has been satisfactorily fixed. The tension of the spring can be determined by attaching weights at J, as shown in Fig. 5, by means of a cord passing over a pulley temporarily attached to the foot-rest, G.

When the weight of the rider balances properly with the weights at J, the reader will know that this is the weight required for the tension of the spring. This spring can be obtained of any spring maker by sending particulars of the tension, length, and thickness required. If any difficulty is experienced in obtaining this spring, a question in "Shop" will elicit the required information.

Cyclists will find that this little appliance, when fixed to their machines, will amply repay the trouble of making, besides giving the satisfaction of knowing that it is of their own manufacture.

The writer has made one and fixed it to his machine (a "Premier"), with the result that the vibration, especially on the arms and hands, is minimised to an extent which will hardly be credited, and he can, therefore, offer these suggestions to readers with the satisfaction of knowing that they will amply repay the labour expended, and that they may be instrumental in overcoming the difficulties encountered by many country cyclists by reason of rough and ill-kept roads.

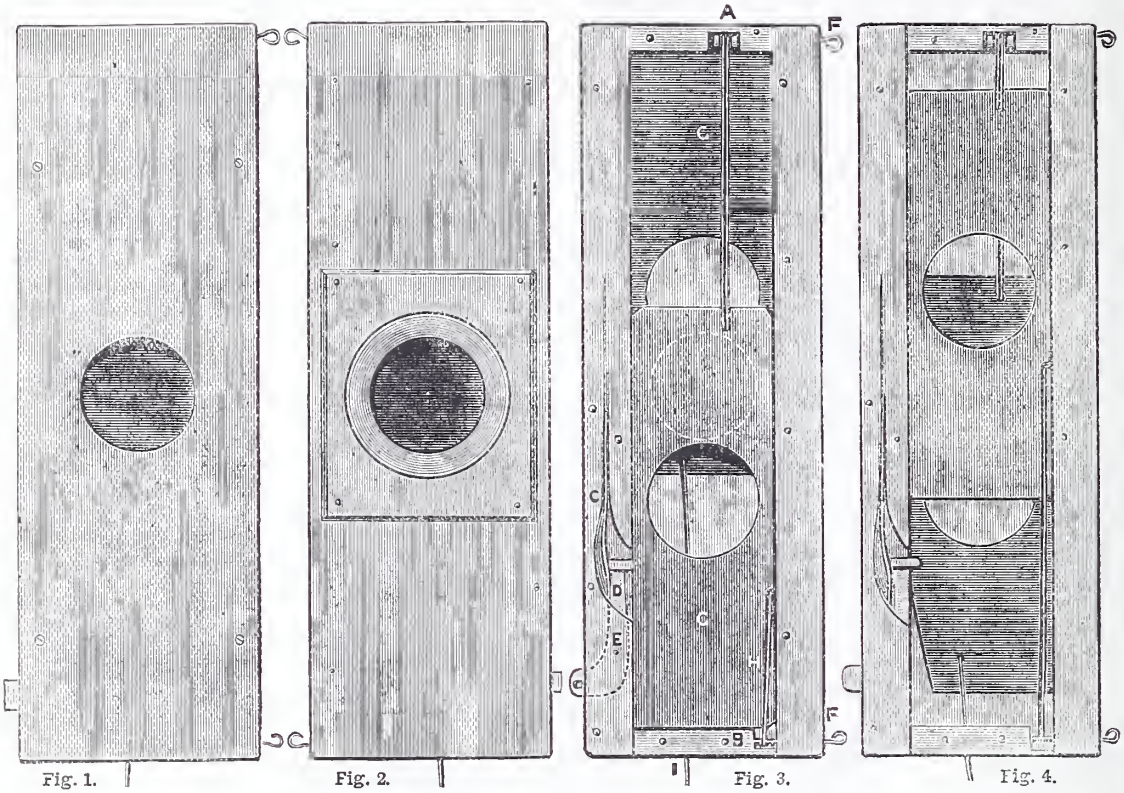

Fig. 1.—Shutter Front. Fig. 2.—Shutter Back, showing Collar to fit Lens Tube. Fig. 3.—Inside of Shutter as it appears after Exposure. Fig. 4.—Inside of Shutter as it appears when set for Exposure.

## AN EASILY-MADE INSTANTANEOUS SHUTTER.

BY FRANK S. MORTON.

EVERYONE who practises photography as a pastime, and many who do it as a business, have more or less occasion to use an instantaneous shutter. There are shutters complicated and shutters simple for all uses, and one of the principal requisites in their make-up is a certainty of action and a lack of jarring propensities, together with a method of regulating their speed for slow or fast exposures. To be complete, they must also be constructed so as time exposures can be made with them readily. An instantaneous exposure can be made with the very simplest arrangement, all that is required, of course, being a couple of pieces of wood with a hole in each, so arranged that one piece is attached to the lens tube and the other is slipped or dropped by it, so that when the two holes are opposite the exposure is made. But a shutter having all the qualities above mentioned must needs be a little more elaborate in its construction. A shutter possessing all these qualifications, and one which can be made at home by anyone, is shown in Fig. 1, the illustration being about half-size. But very little work is required other than can be done with the very simplest of tools, and if rightly made its action is certain and sure, its operation accompanied with not the slightest jar, and the regulating of the speed but the work of a moment. I can best tell how it is made by describing the one made by myself, and I will try and make my description clear, so that those readers of WORK who desire to do so can make one like it with no more difficulty than I had.

I first cut out two pieces of thin wood, $\frac{1}{8}$ in. thick and $2\frac{1}{2}$ in. by $7\frac{3}{4}$ in. Exactly in the centre of each I cut a hole 1 in. in diameter. I used a fret-saw, but careful work with a sharp pocket-knife will answer the same purpose. Of wood $\frac{3}{16}$ in. thick I cut pieces $\frac{1}{2}$ in. wide for the sides and $\frac{1}{4}$ in. wide for the ends, to form a box which, when put together, would be $\frac{3}{16}$ in. deep inside, $1\frac{1}{2}$ in. wide, and $7\frac{1}{4}$ in. long. Before tacking these side and end pieces in place, they were fitted for the working parts as follows:—The two end pieces were notched as shown in Fig. 3 at A and B—at A to allow room for a small brass pulley to run in, and at B in which to fasten a rubber band. The brass pulley may be omitted if too much trouble to make it, as the strings will work all right over the plain wire. The pulley makes things run easier, however. One side piece was cut with a fret-saw, as shown at C, and another cut was made through it at right angles with this, in which the brass catch, D, was to work on the pivot, E. This catch was made of sheet brass of the shape shown by the dotted lines, and had a piece of thicker brass soldered on the end which engages the shutter flap. It is held against the flap, and pressed into the notch at the right moment by the thin brass spring above it. This part of the shutter was all placed in working order before the side piece was nailed to the back; then the side and end pieces were nailed in place, and holes bored for the wires, F, F, to run in. These wires were allowed to project from the outside, to allow of more easy adjustment. Next, the two flaps, G, G, were made. These were made of thin hard rubber, but, of course, any similar material can be used. They were made $4\frac{1}{4}$ in. by $1\frac{1}{2}$ in., with a 1 in. hole in the centre of each. Notches were cut in the edge of one for the catch and the other for the rubber bands, and holes for the cords by which they are worked. To ascertain where these notches were to be cut, one of the flaps was placed in the bottom of the casing and pushed towards the end where the catch was located until the hole in the casing was well covered by the flap. Where the catch was, there the notch was cut The corner of this flap was trimmed off so as to pass by the catch smoothly without interfering with it. A small but stout string was then fastened to a hole in the other end of the flaps, and passed up under and over the brass pulley and back to the second flap, now laid in place, and tied there. In the tying of this string, care should be taken that when it is stretched taut the holes in the flap and the outer cases are exactly coincident. It requires patience to get them so, but the successful working of the shutter depends upon it. Now, from the notch in the top flap stretch a small elastic band, as at H, down to the notch in the end pieces at B, and slip in the wire to hold it in place. In the illustration but one notch is shown, but, to change the speed, have several cut along the edge, so as to give more or less stretch to the elastic, and, consequently, faster or slower working of the flaps. Different lengths and sizes of rubber bands can also be used for the same purpose. A string running from the under flap down through a hole in the end completed the arrangement, and the top was screwed in place. A collar to fit the lens tube was cut out and attached to the back, as in Fig. 2. To set the shutter, pull the string, I, until the catch, D, engages with the notch in the edge of the flap. To release it, press the projecting part

of the catch, which releases the flap, and the two are pulled rapidly past each other by the rubber band, and the exposure is made. Fig. 4 shows the shutter set for exposure, and Fig. 3 shows it after exposure is made. As the two flaps are pulled in opposite directions, they counteract any jar, and the camera is not moved a particle. Time exposures are made the same as the shutter is set for instantaneous. Pull the string until the shutter is open and hold as long as necessary, and then pull out until it catches. A little French polish puts a nice finish on the outside. Being light and of the right shape, the shutter can be easily carried in the pocket.

I have myself found this kind of instantaneous shutter extremely useful, and without doubt it will prove equally useful to such readers of Work as may be induced to make it and try it. It is possible that some may think the mention and description of a home-made appliance such as this unnecessary, on the ground that articles of this kind are sufficiently numerous, and are to be acquired at no great outlay. This is true, without doubt, but it must always be borne in mind that there is, generally speaking, far more pleasure in using any article, be it what it may, that one has made than one that has been acquired by purchase; and then, again, there are many who are compelled to look twice at a shilling before they part with it, and that to such as these, the instructions given will be of importance.

## AN EXPANDING TRAVELLING OR SHOPPING CASKET.

BY JAMES SCOTT.

Its Object — Extra Available Space — Construction — The Body of Article—Adjusting Bars—Coverings for Extra Openings.

*Its Object.* — The members of the working portion of the British community have a notable relish for partaking in excursions to the country or seaside which begin and terminate in a single day, and whilst travelling among them during a journey, it will be seen that there is sufficient evidence forthcoming to warrant the conclusion that working men (and women) lose not one atom of their appetites on such occasions. Sandwiches and bottled beer for the support and stimulation of the adults; sweets, cakes, and tarts for the delight of the youngsters: these constitute a large proportion of the contents of their bags, baskets, etc. And who shall say that these self-same bags, baskets, etc., shall return empty in their owner's possession? Toys, shells, and anything pretty, useful, or memorable, are, if opportunity offers for their security, concealed within them until home is reached.

This being so, it is impossible to say with certainty whether *paterfamilias* will be acting correctly by taking in his custody the market basket, or box, or other receptacle, seeing that to determine whether it will chance to be sufficiently large or not for the purpose may be a difficult task, and to take one of dimensions too bulky to carry about conveniently during the day is not desired.

Under these circumstances, then, a casket, box, or whatever else it may be termed, should be welcomed on numerous occasions as affording means of conveying, either there or back, eatables, drinkables, breakables, etc., the quantity of which may accumulate beyond expectation.

When once I see an ingenious idea embodied in an article of practical utility, and am convinced that that idea enhances that utility, I carry it in my memory. Thus, when my attention was drawn to a representation in a London tradesman's catalogue of a novel form of wicker-work basket, whose sides could be lowered outwards, and whose upright corner edges were covered with silk to prevent any article within from falling out, I decided to remember it; and although I am not by any means barren of original ideas, I fail to see any weak spot within which any reader may reasonably insert the wedge of disapproval in my determination to embody that idea, in a different form, for the use of whomsoever may consider it to contain any merit.

It was while working out a novel form of screen for my readers that I hit upon an arrangement whereby an expanding box might be constructed which could be adjustable to and fixable at any degree of openness within its extreme. That arrangement is shown in the sketches. To have silk or other fabric attached to the corners of a four-side dropping box would hardly be compatible with the rough usage such an article as this would be called upon to undergo; and in the original basket, so far as I could understand it, it must be either in its closed condition or opened to the extreme.

For shopping, too, my working friends might find the casket useful, for the cry would not then be, when the "missus" besought her husband to purchase a few luxuries on Saturday night, "Oh, let it be now; the basket's full"; as the "missus" would retaliate by condemning him for not making an expanding article.

Let us see where extended utility steps in by adopting this suggestion. Presuming that the proportions of the article are always as in Fig. 1, more commodities might be purchased than it would hold; and supposing that it were always as shown in Fig. 2, and that but few articles were purchased: in the former case an extra parcel would have to be carried, and in the latter a bulkier receptacle than required. The difference, then, is struck by having it to expand. This will be much better than carrying two boxes or baskets on the chance of filling both or one and a half.

*Extra Available Space.*—A glance at the drawings will show that the extra space available will be in area about equal to half of that contained within the article when in its smallest compass; in other words, the box is adjustable to an extent almost half as large again as itself, as shown in Fig. 1.

*Construction.*—It is time now that the details are dealt with. Before beginning, however, with them, let me tell my readers that the size of the article is purely a matter of personal consideration; and I shall say no more about this part than to add that the shallower and longer it is made the better, provided sufficient room is allowed for the play of the movable side rails. There is no need to advance reasons for these conclusions; the reader must trust my assertion.

*The Body of Article.*—A bottom board, two sides, and two ends will be required, all to be fitted in such a manner that the surfaces of the upright boards will be flush with the edges of the bottom board, and the end edges of the side boards flush with the surfaces of the end boards. Permanently join the ends to the bottom board and hinge the sides to the same. Fit a frame, having a middle cross rail, between the ends at the top. On each side of the middle cross rail hinge a lid as shown. To the inner side of each side board join a board of the shape A (Figs. 3 and 4) to it at each end, permitting it to work alongside the inner surface of the end board to which it is adjacent. Of the form of handle to be attached to the top I shall say nothing, leaving its choice to the reader's discretion.

*The Adjusting Bars.*—The adjusting bars, which open the two sides of the box to an equal extent, and can be used to retain them at any desired angle within the extreme limit, should consist of a pair of thin rails pivoted at their outer end to the edges of the side boards, and having a hole at each opposite end, through both of which will pass a small thumb-screw, the latter being connected with a nut on the inside of the

casket. A narrow slot should be cut in the end board, to allow of the free play of the thumb-screw. It will be obvious to those who give it a thought that the thumb-screws may be either loosened to permit the rails to work upwards and downwards, or tightened on to the nut to retain them in any desired position. I advise the use of a pair of rails and screw and nut on each side of the box, although not really essential.

*Coverings for Extra Openings.*—The detail which now remains for consideration is that of the covering of the extra openings. It should be plain to all that solid wood tops will be comparatively useless, by reason of acting as obstacles in the way of easy communication with the interior of the case.

After due attention, I have decided that very narrow laths glued to canvas and travelling along the inner surfaces of boards, A, A, A, A, will be the best for our purpose. To the under surface of the top framing securely fasten the upper lath (all of the laths combined should be just sufficient to cover the openings), and carry them over a rod (B, Figs. 3 and 4) fixed between the movable parts, A (of which I have not previously spoken). Attach two or more pieces of stout elastic to the lower edge of it, and finally fasten the remaining ends, without stretching it, to the bottom board. This completes the constructive details.

It may be preferred to discard the laths for some reason or another; if this is so, it will only be necessary to substitute some such material as leather-cloth in place of canvas and laths, and attach it in precisely the same manner as that described in connection with the laths.

I have studied simplicity of appearance for the purpose of making clear the movements of the article, and also to leave free scope for the imagination of my readers to add ornamentation in whichever shape or form they prefer.

## OUR GUIDE TO GOOD THINGS.

*Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

### 60.—The Copus-Booth "Ideal" Patent Castor.

Very recently two kinds of castors that seemed to present certain advantages have been noticed in Work. Here is yet another—the Copus-Booth "Ideal" Patent Castor, which is manufactured in all sizes and forms, plain and ornamental, by the patentee, Mr. Cyrus Copus, 22, Clapham Road, London, S.W., who will send a price list to any applicant, and will show it in action, affixed to tables and chairs, etc., to anyone who may wish to see it. The construction of the castor is very simple, as may be seen from Fig. 1, which shows a plate castor, to be screwed on to the bottom of the leg of any piece of furniture, but the principle is the same in this as in socket castors and any other form. From a horizontal plate at the bottom of a hollow cup, two ears or lugs project, through which an axis—also horizontal—is passed. This axis also passes through a ball, which forms the castor, revolving, *but in one direction only*, on the axis. Now it will seem somewhat strange to some readers that a castor which is an axle castor, and which will run only in a direction at right angles to its axis, should work satisfactorily when attached to furniture of any kind. The utility and good service of the castor depend entirely on the way in which the castor is fixed; and this

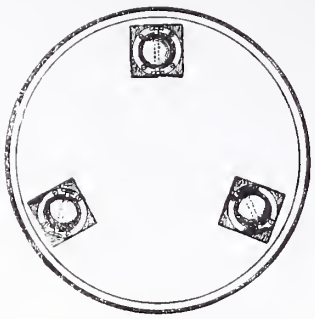

Fig. 2.—Mode of fixing Castors on Round Table.

must be done in a particular way, and generally in a different way, for different pieces of furniture. On looking at Fig. 2, showing how to fix the castors to a round table, it will be seen that the axes of the castors, shown by dotted lines, all point to a vertical line dropped from the centre

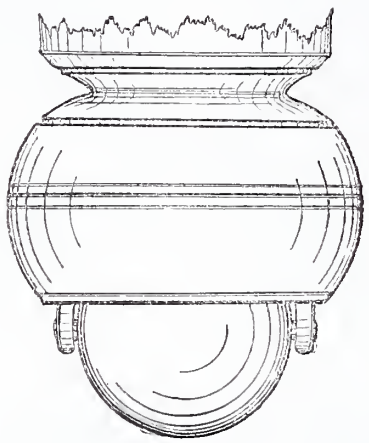

Fig. 1.—The Copus-Booth "Ideal" Patent Castor.

of the table; and in Fig. 3, showing castors fixed to a single chair, the axes of the front castors are parallel to the edge of the front of the chair, and the axes of those behind are at an angle of 45° or thereabouts with it. The proper way of fixing for any piece of furniture is shown in the

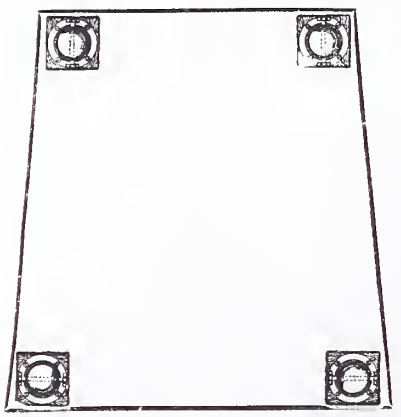

Fig. 3.—Mode of fixing Castors on Single Chairs.

price list issued by Mr. Copus. The prices per set of four range from 8d. to 6s. 6d., according to size and make. I have much pleasure in saying that the "Ideal" Patent Castor is by far the best thing of the kind I have ever yet seen, and should be—as it doubtless will be—in use in every house all the world over. The Editor.

## SUGGESTIONS FOR WORKERS AND HINTS TO INVENTORS.

Waterproof Cloth.—Despite the almost universal use of indiarubber material for waterproof coats and leggings on the part of landsmen, sailors—and, we may add, experienced travellers—still adhere to the more lasting, if cumbrous, fabrics composed of calico or similar material, submitted to a process in which rubber finds no place. This results from two reasons: one, that the beautiful light cloths produced by the rubber factories will not stand much wear and tear; and the other, that a hot climate deteriorates them rapidly, however well faced they may be. A third reason is, of course, the price demanded for really good waterproofs. Many people, moreover, are anxious to know how to make waterproof cloth for purposes other than clothing—such as light tents, awnings, etc. It may, therefore, be useful to state that the best material for both uses is strong grey or twilled calico, made up into the garments, if for wear; or kept in the piece, if for conversion into awnings, etc. When a more substantial cloth is required—such as for travelling tents, etc.—a light canvas may be used, one number lighter than that usually supplied. The cloth being ready, it should be thoroughly dipped in bullock's blood until well saturated, and then hung out to dry in a strong current of air. When perfectly dry, the cloth should be slightly worked with the hands, so as to soften it. Then take ordinary linseed oil and litharge, in the proportion of twenty parts of oil to one of litharge, and mix thoroughly, applying this to the prepared cloth. Repeat the coating twice or thrice, as seems necessary, allowing each coat to dry thoroughly before the next one is applied; but do not expose to the sun. When completed, the cloth will be thoroughly waterproof.

Aquarium Cement.—A good many of our readers take an interest in aquariums; and how to cement the glass sides in an absolutely waterproof manner is, to many, an unsolved problem. Most of the recipes given, although of easy application by manufacturers, are by no means available to amateurs. The latter may be glad to know that twenty-five parts of gutta-percha, carefully melted, seventy-five parts of ground pumice-stone, and one hundred parts of Burgundy pitch, all mixed and melted together, form the best known cement for the purpose. A little deftness in applying (after the fashion of puttying glass in an ordinary window-frame) is necessary; but once properly in place, it forms a leak-defying cement.

Gutta-Percha Substitute.—The growing want of a substitute for gutta-percha is evidenced by the fact that the Société d'Encouragement pour l'Industrie Nationale, of Paris, is offering a prize of 3,000 francs for the discovery of a substance even partially taking its place. Failing this, the prizes will be awarded to anyone giving the most practical hints upon the cultivation of the gutta tree. A second prize of 2,000 francs will be given for the best device for measuring the insulation of the various portions of an electrical plant while the current is passing. The substitute for which the first prize is offered may be natural or artificial. Communications must be sent before the end of November, 1892, to 44, Rue des Rennes, Paris.

Wants.—Amongst the various articles which are advertised for in the technical journals as desiderata are a good process for the Recovery of the Precious Metals, a New Lock, an Improvement in Wood Flooring, and an Improved Brick- and Tile-Making Machine. One would almost imagine that practical finality, in some of these at least, had been reached. But there is evidently scope for inventive genius in directions not apparent to superficial observers. To our minds, the most obvious want of the day in domestic matters is an *absolutely* safe and cheap paraffin lamp. Its principal desiderata are—a provision against any rise in temperature in the oil reservoir, and its immediate extinction when upset. Such lamps can be bought, but the price of present patterns is prohibitive.

## SHOP:

### CORNER FOR THOSE WHO WANT TO TALK IT.

** In consequence of the great pressure upon the "Shop" columns of* WORK, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* WORK *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—QUESTIONS ANSWERED BY EDITOR AND STAFF.

**China and Glass Drills.**—W. J. C. (*Jersey*).—You seem to have misread my replies most thoroughly; (*a*) I did not say that *I* wished to try experiments, but if *you* wished to do so, I would forward recipes. I certainly have not the time to try them. (*b*) Again, read reply to H. S. B., and you will see I did not say two different kinds of drills are used for glass and china. I know of only one drill (or bit, which you like to call it), and that, as I said in reply, is a diamond chip mounted in tin holder. You do not say what your difficulties are. Finally, although I do not object to writing direct, I prefer answers to appear in "Shop," so that all can share the information.—W. E. D.

**Heat for Hatching.**—J. W. C. (*Tottenham*).—The temperature ought to be maintained as nearly as possible at 98°. It might, on occasion, rise to 100° without injuring the eggs, but it should never go as high as 104°. These temperatures are on the Fahrenheit scale.—J. L. D.

**Varnish and Paints.**—TRIO.—In reply to Question A: Oil stain is most suitable for floor margins, etc. You can buy "antique" oak (oil) stain, and this, thinned with turpentine, will make various depths of colour; *burnt Turkey umber* (in oil), used with turps and varnish, also makes a rich and warm stain, hut to those readers who want, before all things, simplicity and cheapness, there is nothing better than a small sample tin of Mathieson Bros.' (Ardrossan, N.B.) dark oak "scumhling." This only requires thinning with good linseed oil, or oil and turps mixed, to be ready for use, and will he sent, carriage paid, for 9d. Further particulars in fifth paper of "Graining" series. For finishing the work, two coats of *hard-drying* oak varnish is best and cheapest in the long run. If one coat of varnish only can be given, the stain must be once coated with warm "patent" or glue size. If a *water* stain is used, the work must be twice sized; hut when size is used, the varnish does not wear half so well, as it forms a film between stain and varnish, instead of these two hecoming one mass—like when painting successive coats of oil paint. A dirty-looking floor will stain *dark* to most advantage. The crevices should be stopped with slips of wood, wedged and glued in, and then chiselled or planed off when set. Query B: The lead work of your stained glass should be ruhhed with turps and rag, and cleanly painted once with quick-drying white lead paint; then a hare coat of oil gold size, and gilded with gold leaf (see "Shop," replies on gilding). Finish with a coat of carriage varnish, stained (if "old gold" colour is desired) with a little finest hurnt Turkey umber. Question C: The answer in "Shop," No. 59, p. 112, "Imitation Marhle," contains all the desired details of painting new wood which you ask for. H. B.'s was a clock case, your article a hookcase; hut the nature and treatment are identical, the colour only differing. Your successive coats should he brought on a little darker than the desired finishing enamel colour. Thanks for your tribute to "WORK's great usefulness"—your "trio" of queries is a very practical demonstration thereof.—F. P.

**Electro-Deposition.**—W. G. (*No Address*).—You make the very common mistake of confounding the electro-motive force of a hattery with its strength. The electro-motive force of a hattery is the pressure of the force in its closed circuit, and is nearly analogous to that of a head of water. This E.M.F. is the same in a tiny cell made from a pipe howl, and one made up in a 10 gallon jar. The strength of a hattery current is not only its E.M.F., or difference of potential between its poles, hut also its volume of current. It is not only the head, but also the volume impelled hy that head. I cannot in this small space answer all your questions relative to the deposition of "gold, silver, copper, iron, nickel, etc." The E.M.F. needed to decompose a solution of any of the metals and deposit the metal in a reguline condition, varies considerably with the composition and tenuity of the solution, and is found by practice. It is usually very low, and rarely exceeds some 3 to 4 volts. The E.M.F. of the current is found hy a volt-meter, and the volume hy an ammeter. Those instruments will he described in WORK when space can be found for the articles.—G. E. B.

**Fixing Pencil Drawings.**—NO NAME.—There are several solutions used for this purpose. The following are the best:—(1) Prepare thin water starch the same as the laundress does, of such a strength as to form a jelly when cold. (2) Thin isinglass reduced hy water to a size. (3) Rice water. These solutions are all applied in the same manner. If the drawing he small, you can immerse it for a few moments in a hath of any one of these you select; if large, apply with hroad camel-hair hrush, as in varnishing. There is no satisfactory mode of fixing crayons.—F. B.

**Toothed Wheels.**—BOWTON LAD.—The question you ask, "How to mark out toothed wheels," is not quite explicit enough, as there are so many different kinds of wheels and teeth, a description of which could not be condensed into the limits of a whole number of WORK, let alone the limited space of "Shop" at disposal. I will explain the method of marking out a simple form of teeth on a spur-wheel, which I hope will be sufficient for your purpose. The term "pitch line or circle" will have to be used somewhat frequently, so I will commence hy describing what it is and how it is obtained. Suppose there are two shafts, *a* and *b*, Fig. 1, to be connected, the one to drive the other at the same speed, hut in an opposite direction to itself. The simplest way would he, supposing the shafts were near enough, and if friction alone could he relied on, to key discs of the same diameter on the two shafts forming their point of contact in *c*, then the one would turn the other as desired. In practice, however, it is found that friction in such cases is useless. So the easiest method of overcoming the difficulty is to cast the wheels with teeth on. Though the outer ends, or faces, of the teeth of each of the wheels overlap the pitch circle of the other wheel, the diameter is always measured, not over the teeth, hut on the pitch circles, which are represented by the two circles, Fig. 1, which, on the teeth of cast-iron wheels, are only imaginary lines, though on the pattern they should he distinct, as most measurements are made either

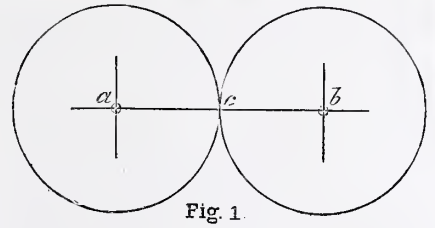

Fig. 1.

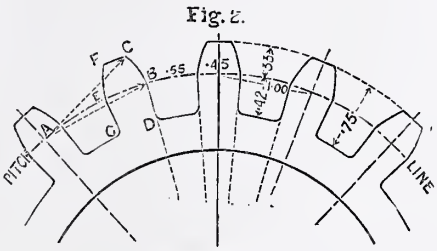
Fig. 2.



Toothed Wheels.

on or from them. I have here taken the case of the two shafts going at the same speed; hut suppose *a* were to drive *b* at one half its own speed, then the wheel on *b* would have to he douhle the size of the wheel *a*, measured on the "pitch line"—that is, as if they were two discs just touching. Suppose the big wheel on *b* changed to *a*, and the small wheel on *a* to *b*, then the shaft *b* would run twice as fast as *a*. The greater the pitch of the teeth of a wheel, the more the points overlap the pitch circle of the wheel it gears with. So that it would not do to calculate the diameter on such a shifting quantity as over the ends of the teeth. I have lengthened out these remarks to engraft the fact of what the pitch circle really is, and why the diameters of wheels are measured on them. The "pitch" of the teeth is the distance between the centres of two adjacent teeth or, for facility in measuring in practice, from the edge of one tooth to the corresponding edge of the next *on the pitch line*. Having decided on the diameter of the wheel and the pitch of the teeth, you proceed as follows:—Draw the "pitch circle" (Fig. 2) equal to the diameter of the wheel wanted, and then, with a pair of spring dividers, set off the pitch round the circle, taking care that the compass point in the last division coincides with the point from which you started—that is to say, the divisions must be exact, and a little extra time spent in setting them out will well repay the trouble. Molesworth, in his "Pocket-book of Engineering Formulæ," gives a simple way of ohtaining the shape of the teeth, the dimensions of which are as follow:—

| | | | |
|---|---|---|---|
| From the pitch line to the top of tooth | = | pitch | × 0·33 |
| Total depth of tooth | = | ,, | × 0·75 |
| Thickness of tooth on pitch line | = | ,, | × 0·45 |
| Space hetween teeth on pitch line | = | ,, | × 0·55 |
| Thickness of rim of wheel | = | ,, | × 0·45 |

If we now add ·33 of the pitch to the radius of the pitch line, and describe a circle, we shall have a boundary which gives us the limit of the ends of the teeth. Similarly, if we diminish the pitch circle radius by ·42, and describe another circle, we shall ohtain the hottom of the tooth. And by again diminishing this last one by ·45, we shall ohtain the thickness of the rim. We must now proceed to set off the half of ·45 (the thickness of tooth) on each side of all the pitch divisions and on the pitch circle, when we shall ohtain the thickness of all the teeth, as at B E, Fig. 2. I may here remark that the part, B E F C, outside the pitch line is called the face, and B E G D within is the flank. In order to ohtain the curve, B C, of the face, we take the centre of the next tooth on the pitch line as centre, and A B as radius, and describe the arc, B C; in a similar manner the face curves of all the other teeth are ohtained. The lines, B D and E C, forming the flank, are simply drawn from E and B to the centre of the wheel, and the corners, G and D, rounded off. From these particulars, you should he able to set out teeth of this form, which are called "straight-flanked epicycloidal teeth," and are almost the simplest form of teeth used. I have chosen to illustrate these, as "Shop" space, as hefore mentioned, is too limited to allow of the somewhat intricate description of some of the more general forms employed. There are also the teeth of bevel and mitre wheels to he described, so I should strongly advise you to ohtain a hook on the subject, as "Elements of Machine Design," hy Unwin, and study the subject thoroughly. "Machinery and Millwork," hy Professor Rankine, also goes into the subject at some length.—P. B. H.

**Water Motor.**—H. V. A. (*Newton Abbot*).—I could not give any guarantee of the efficiency of the motor named. There is, however, no difficulty in getting good water motors. You should write to Messrs. Gwynne & Co., hydraulic engineers, Hammersmith, London, for particulars.—F. C.

**Red Stain and Polish.**—E. J. A. (*Southampton*).—The red stain as seen on the inside of drawers, hookcases, etc., which does not show the grain of the wood, is usually done by mixing Venetian red with patent or glue size, and applied with a hrush. Personally, I prefer to mix with polish or varnish, one part polish to three parts spirits; though I generally save and use for such a purpose any waste stuff, such as may he left from washing out varnish hrushes, pots, etc. If it is desired that the grain of the wood should show, this is done hy giving one or more coats of polish or varnish, which has been previously stained by adding a few drops of red stain, made hy putting twopenny-worth of Bismarck brown in a quarter-pint bottle of methylated spirits. I cannot tell you any particular shop in your neighbourhood where the Bismarck brown may he hought, hut it is sold hy most oil and colour merchants and druggists that sell shellac and spirits. It will be found a most useful stain if made and used as directed. For particulars of how to polish the outside of your bookcase we must refer you to the series of articles on French polishing, which have appeared in Nos. 105, 108, 115, 119, and 123 of WORK. The latter, which has appeared since your letter was written, treats of one of the final stages—*i.e.*, spiriting off.—LIFEBOAT.

**Electric Lights.**—SEPTIMUS.—(1) You ask, What candle-power incandescent lamp will light an ordinary room? This depends upon what your idea of an ordinary room may be, and what sort of light you expect. You should give the size of the room, and say how it is lighted. An ordinary room 12 ft. hy 12 ft. by 10 ft., will require three lamps of 10 c.-p., or two lamps of 16 c.-p., placed at a height of 7 ft. 6 in. above the floor level. (2) Do you think ten (45 volt, 12 c.-p.) lamps would light, ordinarily, a six-roomed house? Here, again, my reply must be qualified hy an explanation of what is meant hy a six-roomed house. If the six-roomed house is at all like a large number of eligible jerry-built structures erected in London for the accommodation (?) of workmen, consisting of a front parlour, 8 ft. hy 8 ft. hy 9 ft.; a back parlour, 6 ft. by 9 ft. hy 9 ft.; a hack kitchen, 4 ft. by 6 ft. by 7 ft., with bedrooms over to correspond, then we might manage to light up the house with the number of lamps mentioned. But, if the rooms are large, and you wish to have them well lighted, you will want at least three such lamps in each of the principal rooms. (3) If you have a dynamo of 120 c.-p., you should have a ½ horse-power Otto gas engine to drive it, as 120 c.-p. will ahsorh rather more than ½ horse-power and an Otto will work up to meet the excess. (4) I do not care to recommend a water motor in your case, as you would not get sufficient pressure to work one economically.—G. E. B.

**Galvanic Battery.**—H. A. O. (*Finsbury Park*).—Although you ask for a galvanic battery, I gather from the other part of your letter that you really want a medical coil. This will he fully described and illustrated in a series of articles on coils, forthcoming when space can be found for them.—G. E. B.

**Banjo.**—H. H. P. (*Bristol*).—If you put a 16½ in. finger-board to a 12 in. hoop, the strings certainly will wear longer. If you tune your 18 in. by 12 in. and 16½ in. by 12 in. hoth to concert pitch, you will find, providing you have strung them both with strings of the same gauge, that the 16½ in. one will feel much looser to the touch, and will, in my opinion, be inferior in quality of tone. I should myself string the 16½ in. one with strings a little thicker than those on the 18 in., and thus make up for the difference in the lengths of finger-board. By doing this, the pull would feel about the same as the 18 in. one; the wear of the strings, I should say, would he about the same. Stringing the short banjo with heavier strings would increase the tension of them to get them up to pitch, so in that case there would be really no advantage. Putting on strings of the right thickness has a lot to do with the wear of them. If the strings are too thick they will not stand the increased tension to pull

them up to pitch, and consequently break. Again, the quality of the strings has to be taken into consideration. Some players *will* buy the cheapest strings they can procure; the consequence is, they are continually breaking, and no wonder—how can a string costing 2d. be expected to be as true and wear as well as one costing 4d.? The higher-priced string is really the cheapest in the end, providing the dealer selling them is conscientious, and tests the strings he buys from wholesale houses before offering them for sale to the public. No one would believe, except those who have experienced it, the trouble it is for a maker or dealer to get really good strings for the banjo, and which can be sold at a reasonable price. Strings from a certain maker may be very good, but the next consignment from the same maker may turn out worthless. Then, again, some players' hands perspire very much in warm weather, which means to them an endless breaking of strings; some do not keep their nails short enough, and therefore cut the strings; others do not acquire a proper touch; the nut, tail-piece, or machine-head (if one is used) may have sharp edges and cut them: so you see there are several points to be studied in stringing that much-abused and maligned (but very popular) instrument—the poor old banjo! Wire strings on an ordinary banjo are an abomination, and are not suitable for an instrument without raised frets. There is a string made, or supposed to be made, from Japanese silk, which stands very well, and would be very suitable for players with warm and perspiring hands. The tone is not so good in quality as gut, and when it gets a bit frayed the tone seems to leave it altogether, which are its disadvantages; on the other hand, it stands well. I have also tried a string made from silk exactly similar to "Acribelle" string for the violin, but thinner. The tone of this is also not so good, and pulls much harder than gut, which would prove a great annoyance to a *good* player. On a banjo with a short finger-board the fingering for the high notes would be closer, the frets not being so wide apart as on a long one, which would be considered a disadvantage by some players. I should certainly say the 18 in. by 12 in. "jo" would be the most saleable. At any rate, it is with me.—J. G. W.

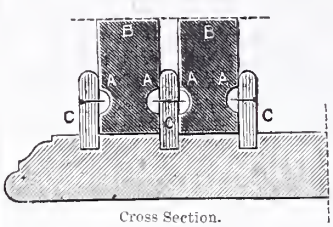
**Banjo-Making.**—A. E. (*London, N.*).—To answer your query in full would take up too much space here. Refer to back numbers for July 27, 1889, November 2, 1890, Nos. 70, 75, 79, 81, 93, 106, 109, 113, 121, 124. I presume, from your letter, that you are a novice in banjo-making, so should advise you to make an instrument not quite so elaborate as one with an engraved metal finger-board and engraved hoop. You would then be able to see and correct the little faults which would be almost sure to appear in your first attempt, when making your second and more elaborate instrument. I must refer you to the articles that have appeared in WORK for instructions how to engrave your hoop. Metal facings on the handle are generally made of German or nickel silver, and fixed on by drilling a series of holes in the metal, countersinking the holes a little to receive the heads of the screws, then filing down screw-heads level with finger-board. Use screws made of German silver. To engrave and nickel-plate the metal as you propose, you would have to solder pins on the underside of metal to drive in and fix to the handle. You would not be able to fix it from the face side after it was plated. I should advise you to use the German or nickel silver in preference to the last-mentioned; you can true it up and make a good job of it, which is more than you could do with the plated face. If you intend to use gut strings, do not fix a machine to your banjo. They are a nuisance; you will rarely find a player of experience using them. They are all right for show, but you should make appearance a secondary consideration, placing utility and comfort in playing first.—J. G. W.

**Iron Feet for Boots.**—L. L. (*Nottingham*).—The makers of the iron feet marked $\frac{\text{U. \& Co.}}{\text{L}}$ are Ullathorne & Co., 9, Gate Street, London, W.C., and Albert Street, Birmingham.—W. G.

**Instruction in Fretwork.**—T. M. (*Birmingham*).—There has not, so far as I am aware, been any article in WORK specially devoted to elementary instruction in fretwork; but from the very first number designs for this art, correspondence regarding it, and useful suggestions for those who follow it, have been of frequent occurrence—so frequent, in fact, that it would be useless for me to attempt any list of them. T. M. would find an advantage in getting a complete set of the back numbers.—M. M.

**Picture-Frame Gilding.**—G. F. R. (*Redditch*).—On p. 262 (third column) you will find preparations for oil-gilding in their order. First, thin white: then stop up defects in frame; second, clay; and so on. Thick white is only used as a solid foundation for burnishes or flat work, and must not be used on ornamental work, as it would fill up the ornament; also matt and burnish gold-size are only used for burnished parts of frame or flats that fit inside other frames. Clay is procured at the artists' colourman's—Rowney's, for instance—and is ground fine by machinery, known as gilders' clay. Make a weak size (such as described on p. 263) for finish size; and as this is to be put on after gilding, a little colouring matter is mostly used. A few drops of white lacquer and metbylated spirits in the finish size will give a white appearance to the gold, or a little saffron will give a yellow tinge, according to taste. Spanish annatto is sometimes used, or other dyes.—H. E. M.

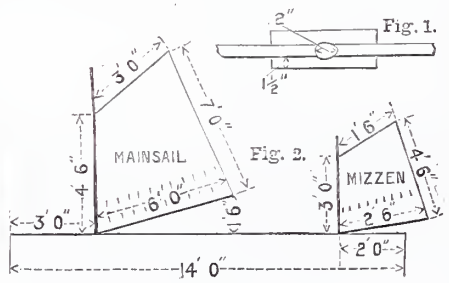
**To Guide Sliding Doors of Bookcase.** — A READER OF "WORK."—Perhaps you may be acquainted with the ordinary way in which sliding doors of bookcases are made to travel. The sketch is a cross section illustrating the details of the method, with the exception of the pieces A, which I have introduced, and which I will presently explain. Your grievance seems to be centred in the annoyance created by the difficulty of sliding a long, narrow door comfortably and regularly. There is one way by which I think you may effectually overcome the difficulty; and in full justice I must say that my present suggestions result from the simple but excellent device for running drawers truly given by E. W. in No. 121, page 258, Vol. III. B, B, represent the thicknesses of doors; C, C, C, of door runners fixed completely along the front at top and bottom of the top carcase of the bookcase; and A, A, A, A, are the beads screwed along the runners in the positions shown in connection with them. You must groove the top and bottom styles of each door, and place the beads loosely into the grooves, after having taken note of the correct distance each is situated from the outside bottom and top edges of the doors respectively. Then fit the doors within the runners, and screw A, A, A, A, in position, along which will then travel the doors; A, A, A, A, serving as guides to retain them as parallel as possible to the plane of the bookcase. If guides could be fitted to the middle of the doors, so much the better; but with only the amount of opportunity I have at present, I cannot evolve any convenient way. You will find these details rather "ticklish" to fit, but undoubtedly they will tend to prevent the stickiness you righteously complain of.—J. S.



Cross Section.

**Sliding Doors of Bookcase—A, A, A, A, Beads, as Guides to be fitted to Top and Bottom Runners respectively; B, B, C, C, C, Door Runners.**

**Canvas Canoe Sail.**—T. R. (*Stoke Newington*).—I do not think it would be safe to use a sail on a canoe as described, for use on the sea; but it might be used with a sail as follows on a river if the captain could swim. If a sailing canoe is desired, I should advise the following alterations to be made: 2 ft. 8 in. wide, with straight stern-post for fixing rudder to; also make provision for fixing two masts, as shown in Fig. 1., and in position shown in Fig. 2. The foot of mast should rest in wood shoe in keel. I think a standing lug-sail would be best, with two reefs in mainsail and one in mizzen. When trying the sail, T. R. could trim the canoe with a few sand-bags as ballast. A canoe like this would easily accommodate two, and would be much safer, the crew acting as shifting ballast.—J. B. F.



A Canvas Canoe.

**Watch-Case—Engine-Turning or Engraving?**—T. H. (*Ballina*).—Which is it that wants doing to your watch-case? If it is engraving, send to Corke Brothers, 29, Northampton Square, Clerkenwell, E.C. If it is engine-turning, then send to J. A. Groom, 8, Sekforde Street, Clerkenwell, E.C. To either you can send the watch-case with perfect confidence, for it will be well and reasonably done. If you particularly desire an estimate, then send a sketch of its size, with full details, and you will doubtless obtain one by return of post. Insufficient details are sent in your letter for forming any idea of cost.—H. S. G.

**Improvements on Patents.**—IDEAS.—It is quite within the province of any person to make an improvement or improvements on an existing patent or patents, but he will not be allowed to apply it or them to, or use them with, the original patent during the duration of the patentee's exclusive right, except by a licence from the owner of the existing patent. Justice Tindal has said: "When a party has obtained a patent for a new invention made by his own ingenuity, it is not in the power of any other person, simply by varying in form, or in other immaterial circumstances, the nature or subject matter of that invention, to obtain either a patent for it himself or to use it without the leave of the patentee, because that would be, in effect and substance, an evasion of the right." Vice-Chancellor Malins has held that "No doubt a man may make an invention which is partly covered by an existing patent, but he cannot use it without the licence of the patentee. He may wait for the expiration of the patent, and take out one himself, if his invention be novel; and that patent will be valid." Lord Westbury has said: "It is extremely desirable that when a beneficial idea has been started by one man he should have the benefit of his invention, and that it should not be curtailed or destroyed by another man simply improving upon that idea; but if the idea be nothing in the world more than the discovery of a road to attain a particular end, it does not at all interfere with another man discovering another road to attain that end." Lord Chief Justice Hope has said: "A patent cannot be taken out solely for an abstract philosophical principle—for instance, for any law of nature or property of matter apart from any mode of turning it to account in the practical operations of manufacture or the business and arts and utilities of life. The mere discovery of such a principle is not an invention in the patent law sense of the term without the application of the principle to a practical object and end; and without the application of it to human industry or to the purposes of human enjoyment, a person cannot, in the abstract, appropriate a principle to himself." Chief Justice Eyre has said: "Undoubtedly there can be no patent for a mere principle, but for a principle so far embodied and connected with corporeal substances as to be in a condition to act and produce effects in any art, trade, mystery, or manual occupation, I think there may be a patent." Justice Kekewich has held that "A man may invent an idea or a principle—that is to say, a man in his studio may by study, with or without illustrations and experiments, evolve the principle or idea that such a result may be produced by such and such means, and that is, in truth, an invention, supposing it to be new. But that is not an invention according to Patent Law. It is not an invention for which he can receive any protection. In order to bring himself within the law, and reap any advantage from his invention, he must apply it in some concrete form." It should be well understood that a legal patent cannot be obtained for an "idea," which is not by any means an invention or a "property," and can only be made one by giving it a practical form—*i.e.*, by showing the mode in which the "idea" can be made useful, or in other words, by devising a means or mode by which this "idea" may be brought into a practical shape. Unless this is done, the "idea" is useless, of no value to anyone, and must remain so until it receives a practical development. Now, if our correspondent has embodied his "ideas" of improvements in a complete manner, so as to be satisfied of their practicability, and got them into the shape of models or drawings to prove that they are practicable, then he should ascertain that they are novel, and likely to be useful. When, however, he has done this, there still remains the difficulty of having to deal with unprotected inventions, and having to submit them in this state to the inspection and *bona fides* of others whose interests are not those of the inventor. Most persons would say, "Apply for 'provisional protection.'" But then comes the question, is it worth while to do so? seeing what views the law holds on the subject, and the possibility of the existing patentees declining to take them up? Not knowing in what direction our correspondent's improvements lie, we are unable to give him any useful advice, as it might turn out that the patents he alludes to are invalid, in which case the advice would be quite different, cases are so dependent on circumstances. The best thing we can recommend our correspondent to do is to refer to, and read and study, the article relating to patents in WORK, No. 44, Vol. I., p. 694; the reply to R. S. W. (*Leeds*) in No. 109, Vol. III., p. 77; and the reply to F. S. S. (*Leicester*) in No. 118, Vol. III., p. 222. The want of general knowledge of, and a correct understanding of, patent law and its requirements, are great difficulties to inventors, and these are greatly increased by the ignorant, incapable, and presumptuous crudities and lucubrations of amateur dabblers and incapables, who are so fond of parading their ignorant *dicta* as proofs of their erudition and capability, which act prejudicially to the interests of such as are foolish enough to be caught by them.—C. E.

**Unworkable Gold.**—SILVERSMITH.—The quantity of gold in question being so small, it will be cheapest to sell it to the refiner; but if you have a small melting-pot to hand, and can run it down in a furnace where the fumes can be carried away by the flue, then re-melt it, and when fluid use corrosive sublimate as a flux. Be very careful with this, for it is a deadly poison; and the chemist, before selling it, must be satisfied that it is for a genuine purpose. Have you tried stirring it up, when in a fluid condition, with sal-ammoniac? There is a chance that this might make it workable. Details of the colour and grain of the fracture would have been of assistance, for other causes may be at work than the two I have in my mind in advising the two fluxes above; for example, certain proportions of copper in alloys will very often make gold difficult to use. Your way of making rings from a grain of gold is the same that sailors have when they wish to make a silver coin into a ring—viz., by driving a hole through the centre and then

hammering it into shape on a marlinespike. This is too rough a method for anything but fine gold or silver. Why not follow out the method given in two replies to INDEX on p. 357, No. 74, and p. 648, No. 92, of Vol. II. of WORK? In these I warned him, too, of the very fix you are in with your bad gold.—H. S. G.

**Waterproof Sole Leather.**—A READER.—You ask "the best way for rendering sole leather—that is, hard leather—used in pump work, waterproof." Now, as all boots or shoes, made pumps, are made inside out, and turned to their right side after they are sewn, hard leatber is never used. Moreover, pumps are nearly always used for dancing and evening wear, where waterproofing would not be necessary. I hope I may be excused for the above, but I mention it that I in future may answer a question without jumping at a conclusion; for in this case my conclusion is tbat you want waterproof leather for washers, etc., in suckers of water pumps (plumbers' work). For this purpose, get a shallow vessel—as a frying-pan—and put some water in it. Put some tallow and neatsfoot oil (equal parts) into a jar, or any stone vessel large enough to receive the pieces of leather; put the leather in the jar with the oil and tallow, and jar into the pan, and put it on a slow fire to simmer (not boil). It is best not to stand the jar on the bottom of the pan, but on a piece of wood ½ in. thick. It will not be necessary to use leather very hard, for, when taken out of the oils and let get cold, it becomes harder than it originally was. The stout but inferior portions are most absorbent, as the fibre is not so dense. It will not want to be left in the oils—only about five minutes—and when taken out it can be thrown into warm water. This will take the surplus grease off the outside, and when tbe water is cold it can be taken off the top, and put again into the jar, ready to use again.—W. G.

**Two-Foot Slide Rule.**—L. W. (*Somerset*).—I may say that with this rule there can be a great variety of calculations made upon it. In timber measuring L. W. will be able to measure up boards and planks, round timber and round taper timber, as well as painters' and glaziers' work, tiling and slating, bricklayers' work, mensuration, etc. Also liquid measure and the calculation of the mechanical powers, such as the wedge, levers, wheel and axle, etc. There is no doubt that to have an instrument like the slide rule it may be very handy when one is in a hurry. I may say that I never use one myself; not that they are inaccurate—far from it; if the slide is worked properly, according to Rabone's instructions, everything will be well—but one might make a mistake. I would sooner depend upon calculating; but, of course, that is only my opinion, and everyone has his likes and dislikes on such matters. I cannot give here the tables for calculating by the slide rule, that would be an infringement on Rabone's copyright; but if L. W. would like it, I will send him a book I have on his slide rule, if he will pay the postage.—T. R. B.

**Artificial Foot.**—DUNDEE.—You cannot do better than write to James Gillingham, surgical mechanician, Cbard, Somersetshire, who has made this subject his special study.

**Surveying.**—KELLY.—A cheap way for you to gain information would be to write to the Civil Service Commissioners, Cannon Row, London, W.; and if, after receiving their answer, you do not think tbe matter is sufficiently clear, I should advise you to get Cassell's "Guide to Employment in the Civil Service" (3s. 6d.).—E. D.

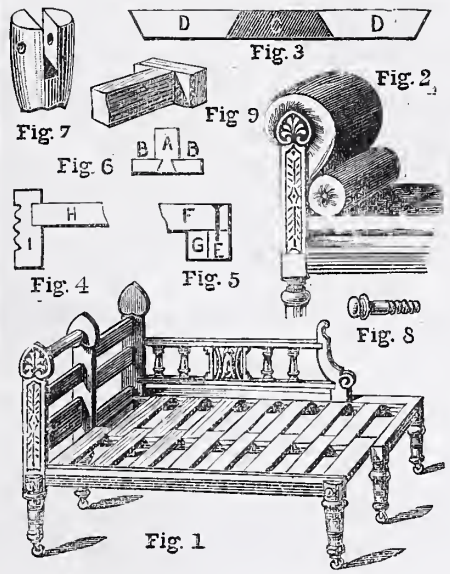
**Sundial.**—A. R. (*Birmingham*).—You will find the information you want in Vol. II., pp. 18, 104, and 139 (Nos. 54, 59, and 61). The first article treats of horizontal, tbe other two of vertical, dials. Probably that in No. 54 will serve your turn. When you have read it, you will see whether your gnomon will suit, and why it will or will not. For engraving on your sheet of brass you will need a graver, which you can buy at any tool maker's in your town—say at Townley's in Ball Street.—A. Y.

**Angle for Lathe Centres.**—INQUIRING SUBSCRIBER.—There is no settled standard for the point of the lathe centres, but there ought to be, as it is impossible to ensure your work running true if transferred to another lathe, which bas the centres of a different angle. In America the angle of 60° is almost universal, and all American mandrels, taps, etc., have centres in them of that angle. This angle is thought rather too sharp in England; yet, from the convenience of having a standard, and from the ease with which a gauge for 60° can be made in a bit of sheet metal with a "three-square" file, this angle appears to be gradually becoming the standard in England too.—F. A. M.

**Golf Balls.**—GOLFER will probably find his difficulty disappear if, instead of softening his gutta-percha by immersing it directly in the water, he softens it in a *water-jacketed* vessel, such as a glue kettle, as tbe gutta-percha softened by this means will be perfectly dry. In the absence of a glue kettle a double porridge pan would be found to answer equally well; or a tin can of sufficient size, and having a well-fitting lid, might be utilised by placing the gutta-percha therein, and tben heating in an ordinary saucepan partly filled with water.—QUI VIVE.

**Bending Brass Tube.**—MIKADO.—I should like to know what shape you wish to bend the tube—whether into a circle or part of a circle; and if so, what is the size or radius of same? And are you quite certain that it is brass tube, or is it brass-cased, which very many people call brass tube? If you will kindly supply these particulars, I shall, no doubt, be able to help you.—R. A.

**Couch Bedstead.**—PATTERN MAKER.—I have overbauled your letter and sketch, and have applied the fullest possible care thereto. I have decided that the form of couch I have drawn herewith will be preferable on both tbe points of strength and facility of action. First, concerning strength. Your sketch shows the front leg blocks of the couch as drawn away from the back parts with the movable framing. This course, if not quite impossible, will prove a source of extreme weakness. All true leg blocks *must* be fixtures to afford accommodation for the framing; otherwise, in the event of tbe seat-front blocks being drawn forth with the movable slides, no substantial support can possibly be substituted, meanwhile, at the corners where the front rail meets the side rails. The sketcb will show you the general construction advisable. Between the blocks of the legs in connection with the couch head-rest should be mortised a stout rail (A, Fig. 6), to which, in turn, will be joined two slips (B, B, Fig. 6). The back ribs will best suit the purpose if dowelled or screwed *above* the back and front rails of the seat proper. Each



**Couch Bedstead. Fig. 1.—Frame of Couch: the front portions slide horizontally backwards and forwards upon the back portions. Fig. 2.—Upholstered Scroll and Cushions of Couch. Fig. 3.—Section—C, Front Slide; D, D, Back Fixed Rib. Fig. 4.—Section—H, Movable Slide; I, Extreme Front Rail. Fig. 5.—Section—E, Very Long Rail passing the whole of Couch; F, Movable Slide; G, Front Rail of Back Frame (middle in the sketch). Fig. 6.—Section—A and B, B, Rails fixed between Back Couch Heads, above Leg Blocks. Figs. 7 and 8.—Top of Extreme Front Legs and Attaching Screw respectively. Fig. 9.—Back of Couch-Head Slides. (The Front Legs are quite detachable.)**

should be in section (as D, D, Fig. 3), as the movable slides will retain their position better, and act more firmly, if they are made in section (as C, Fig. 3). Over the top of the back and end seat rails respectively might be glued narrow strips to form a rebate for the purpose of accommodating tbe cushions. The front extremity of the end strip ought to be mitred, and project slightly, to meet the end of the movable front (extreme) rail, which should be similarly mitred. Something must be provided to prevent the front slides from coming completely away from the back part of the article; and this is found by screwing a rail (E, Fig. 5) from one end of the couch to tbe other, and within the framing, underneath, and to the ends of the movable slides. This necessitates having the exposed portions of these rails or slides shorter by the tbickness of the back rail of the framing than the fixed or back ribs, as it will be understood that the rail E (Fig. 5) will prevent the movable slides from passing over the back frame rail. The front slides should be mortised into the movable front rail (as H, Fig. 4). This permits the top of the rail I (Fig. 4) to act in correspondence with the strips mentioned previously as forming a rebate for seat-cushion. You will probably understand that the front couch-head slides are mortised to it (the couch head), and travel between the fixed mortise rails between the two back uprights. To each of these slides screw a stop-piece (Fig. 9). The only important point which now remains, and one which I do not think you can possibly improve upon, is the support of the fronts of the slides as a whole. Seeing that the front leg blocks proper cannot be moved, it would be folly, so far as the appearance of the *couch* is concerned, to have, on the movable rail and under the movable couch head respectively, blocks of the same size as the fixed ones, to receive the needful detached legs; therefore I advise you to bave thin strong blocks, and legs sbaped at top (as in Fig. 7). The top mortise will then fit over the blocks, and if holes are pierced through them and the legs, wooden or metal screws could be used to securo them in position. Used as a bedstead, tbe appearance of these legs will be of little consequence (I show them different in character for the obvious reason of distinguishing them from the back ones, to avoid misconception as to which are fixtures); but if you consider the holes in the blocks detrimental, you must fill them during the daytime with small patères. The best shape for tbe stuffing is shown in Fig. 2. It should be so attached tbat only the thickness of the movable couch head will show when all is closed. A removable bolster used in connection with it will answer well. It seems to me that your sketch represents a band of material round the two long seat cushions to form a hinge. Now, I advise you to dispense with tbis method, and, instead, completely finish the two separate cushions, and then stitch a piece of material the whole length of the cushions, of a width equal to the two combined, neatly and securely to both edges at one side. They can then be opened, as you desire, to cover the whole hedstead. You must determine the sizes of the couch—perhaps 6 ft. long by 4 ft. 6 in. wide will do. I advise the use of an extra, loose, cushion, of the shape in Fig. 2, hooked over the front couch head at night. See, for constructive details, papers on ottomans, etc., in back numbers.—J. S.

**Running Block Tin.**—J. McD. (*Glasgow*).—This querist asks how to make block tin run into brass moulds, and how to bring it to a very smooth surface. Well, I can only reply that you must melt the block tin in a ladle with a spout to it, and then pour it into the mould; and as to the smoothness of the surface, if the mould is smooth, the casting will also be smooth, and *vice versâ*. N.B.—In pouring metal into a mould, take care that the mould is free from damp or moisture.—R. A.

**Spherical Slide Rest.**—X. Y. (*Wandsworth*).—To describe a spherical slide rest fully would occupy three or four articles. I think, therefore, I must refer you to the fifth volume of Holtzapffel & Evans' work on ornamental turning.—J.

**Moulding.**—H. T. (*West Bromwich*).—The best cheap book is entitled "Practical Iron Founding," price 4s., published by Messrs. Whittaker. A more expensive book is "A Practical Treatise on Casting and Founding," price 18s., published by Spon. Two excellent books are "American Foundry Practice" (West), price 10s. 6d.: and "Moulders' Text-Book," by the same author, price 12s. 6d. They are both published in America by Wiley & Sons, New York, but are obtainable in England of Spon, Strand, E.C., or Trübner, Ludgate Hill, E.C.—J.

**Mending Incandescent Electric Lamp.**—W. B. (*Manchester*).—If you have some skill in soldering, and can manage a delicate job, the broken platinum wire can be repaired in the following manner: With a fine sharp file clear away a small portion of the glass around the end of the platinum wire, so as to expose about ⅛ in. of the wire. Get a piece of No. 24 copper wire, clean one end, and flatten it out into thin foil. Anneal this on a piece of red-hot iron, clean it with a scrap of fine emery cloth, and tin it as for soldering. This done, carefully trim it with a pair of sharp scissors, and bend it with a pair of small pliers to form a socket fitting tbe exposed end of the platinum wire. Give this a touch of the soldering flux or fluid, fit on the prepared socket, and solder it on with a small soldering bit, or a carefully directed blowpipe jet. After this is done, the copper wire can be cut off to the required length, and bent to form a loop.—G. E. B.

**Broken Mercury Column in Barometer.**—R. P. (*Islington, N.*).—The column of mercury in your barometer tube has been broken by a sudden jolting of the instrument when upside down, and thus some air has been shaken into the tube. This must be expelled either by shaking all the mercury into the upper part of the tube, or by heating the tube when upside down, and thus expelling the air from the mercury. Unscrew the clasps which hold the tube, take this out, and hold it upside down, so as to cause the mercury to run into the closed end. Gently tap the tube with the fingers, and thus try to shake the mercury into one unbroken column. If this fails, the tube must be warmed over a spirit lamp carefully, then heated at the closed end and upward, inch by inch, until all the air has been expelled. This done, cork the open end, turn the tube suddenly, withdraw the cork gradually, and thus allow the column to fall into its right position. This done, restore the tube to the frame.—G. E. B.

**Electric Belt.**—R. D.—Still they come! Inquiries about magnetic belts, galvanic belts, and electric belts, under several different names. Such belts and appliances differ only in name, and my reply concerning one is applicable to them all. If you wish to amuse yourself in making one, follow these instructions. Make a body belt of flannel, or of canvas, or of webbing. Get some pieces of sheet zinc and sheet copper, the size and shape of pennies. In the centre of each fix, by soldering or otherwise, a small brass screw long enough to just pass through the material of the belt and enter a screwed nut on the other side. Fix them in the belt just where you *fancy* they will do you most good. Coat the inside part of the belt with soft wash-leather, and stitch around the discs of copper and of zinc. Get some strips of thin brass, long enough

to connect one stud with another; drill holes in each end to pass over the screwed ends of the studs, and connect the studs as you would a battery—copper to zinc in series throughout the belt. The nuts employed to do this may be rounded at the edges and ornamented, if you like to see them look nice. You will now have a belt equal in value to one costing five guineas at the shops, as its value will depend upon the faith you have in such appliances. See my former replies on similar subjects. —G. E. B.

**Electric or Magnetic Appliances?**—F. J. S. (*Durham*).—As the magnet adheres to the so-called "Electric Soles" when these are placed in contact with a magnet, you have ample proof that they are made of iron or steel, not of zinc and copper. They may be made of magnetised steel, in which case they are not electric, but magnetic, appliances. Zinc plates will not attract nor be attracted by a magnet, nor can a belt containing zinc plates be magnetised. An electric belt, made up of alternate strips of zinc and copper, will not require being magnetised nor "electrified." It forms in itself an electric apparatus capable of generating a current of electricity when the flannel of the belt is moistened with vinegar or with the saline perspiration from the body of the wearer. The evidence of such a current may be obtained by connecting the two end plates (copper at one end and zinc at the other) with a delicate galvanometer, when the needle of the instrument will be deflected.—G. E. B.

**Old Oil Paintings.**—A. E. S. (*Wootton Bassett*). —This process requires great care and experience, especially where the picture is obscured by a coat of hard old varnish. This may be removed by spirits of wine and turpentine; but great care must be taken to stop their further action, when the varnish is dissolved, by using water freely, or they will attack the paint as well. Where the picture is merely obscured by dirt, wash with clean soft water, using a soft leather or a sponge. Then dry, or rather polish, with a silk handkerchief. When dry and bright, take a handful of medicated wool, and pour upon it two or three drops at a time of clear nut or linseed oil, rubbing well into the picture—the smallest quantity suffices; then polish dry with a silk handkerchief.—F. B.

### III.—QUESTIONS SUBMITTED TO CORRESPONDENTS.

**Microphone.**—J. S. (*Enfield*) writes:—"Can anyone inform me where I can obtain a small quantity of the best oven-made coke?"

**Oval Bradawl Handles.**—C. C. E. (*Lincoln*) writes:—"These are beautifully made in soft wood, such as beech, and I shall be greatly obliged if any reader will tell me how they are turned or fashioned, and where their manufacture can be seen."

**Windmill.**—YOUNG writes:—"Would any reader kindly inform me, through 'Shop,' how to make a windmill to average about ½ horse-power, its probable cost, etc?"

**Inlaying.**—J. T. S. (*Sheffield*) writes:—"I am anxious to do some fret inlaying with my machine, but do not quite see my way. I should be glad if any reader would give me the benefit of his experience, and say how the holes, bored to put the saw through, are hidden afterwards? Is the wood cut at an angle to make the top piece fit the lower hole tightly? Any hints, or reference to a source of information, would greatly oblige."

**Mining.**—PUZZLED writes:—"Could any reader tell me of a good mining school in the Western States, U.S.A.? Any information on the subject would be gladly received."

**Varnish.**—J. M. P. (*Preston*) writes:—"Will any readers of WORK kindly give me a good receipt for making bookbinder's special varnish?"

**Rustic Woodwork.**—B. J. B. (*Boddington*) writes:—"Will any reader of WORK kindly give rough sketch of rustic bridge, and rustic arch for each end, with a few hints as to best plan of construction? Also I should be glad of rough plan for a timber storing shed, to be built of timber, and covered with galvanised iron."—[Much on rustic work has already appeared in WORK, Nos. 113, 115, 117, 119, 121, 123.]

**Fretwork Picture Frame.**—T. W. A. (*Stockton-on-Tees*) writes:—"Will any reader of WORK kindly tell me how to join a fretwork picture frame? It is 20 in. by 24 in. I should have to cut it in two parts. I should also be glad to know of any good book on fretwork."

**Mail-Cart Handles.**—ADIA writes:—"Can one of your numerous readers tell me where I could get some mail-cart handles, either in Birkenhead, Liverpool, or London? I want those that are bent."

**Bath, To Heat.**—ROUND O writes:—"Could any of the readers of WORK tell me how best to heat water for a bath having no connection with a boiler or fire, only cold water attached to it?"

**Indiarubber Mat.**—ROUND O writes:—"Our door-mat, which is of special design, is parting in two in the middle. I shall be glad to know what will repair it, and how it can be done."

**Pocket Boiler.**—W. M. (*Derby*) writes:—"I should like to know how to make a small pocket tin for boiling water, etc. Lamp—to fit inside when not in use—to burn paraffin or other common oil, and yet not deposit soot. Is this practicable? Would some form of Argand be suitable?"

### IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Copper Sheets.**—HUMPHREYS & ROSSITER (18, *Arthur Place, Camden Street, Birmingham*) write, in reply to ANXIOUS (see page 267, No. 121) to say that they supply copper sheets 4 in. by 2 in. by ⅛ in. thick.

**Fretwork Thin Lines.**—ROUND O writes, in reply to query by PUZZLED (see page 222, No. 118):—"If your wood is not too thick, it could be pierced with a machine needle fixed into a hand vice. You could get a needle as fine as any fret-saw, which would not mar the job. I have seen such lines cut in with a carving tool, which may answer better."

**Model Electric Lights.**—S. T. (*Horley*) writes, in answer to J. H. (*Wolverhampton*) (see page 254, No. 120):—"You can get carbon plates, dynamos, and electrical apparatus of every description, and cheap, of W. Wells, engineer, Toovies Worth, Crawley, Sussex. Send the size of articles you want, and he will quote the prices for same."

**Compound Engine.**—H. B. (*Disley*) writes, in reply to PUZZLED (see page 286, No. 122):—"The steam exhausted from the high-pressure cylinder *does* exert a back pressure almost equal to the pressure exerted upon the low-pressure piston. Whatever difference of pressure there is is due to condensation. The back pressure is amply compensated for by the increase of area upon which the steam acts in the L.-P. cylinder. The receiver will be quite large enough in the form of an ordinary cylindrical pipe of an area equal to the steam-ports in the L.-P. cylinder. A good rule is to make the port in the H.-P. cylinder = ¼th area of cylinder, and in the L.-P. cylinder ⅛th area of cylinder. Some of the best makers make the L.-P. cylinder twice the diameter of the H.-P. cylinder—*i.e.*, four times the area."

**Chair Seats.**—M. (*Bishop Auckland*) writes, in reply to W. J. B. (*Deptford*) (see page 270, No. 121):—"I have found the seats wear very well with fair usage. You can get them in two or more different thicknesses from the ironmongers. If you want to make them in one piece, use birch or beech, but they will cost more."

**Portable Furnace.**—H. B. S. (*No Address*) writes, in reply to H. B. (*East Hartlepool*) (see page 270, No. 121):—"You wish to have the dimensions, etc., of a portable furnace for melting about 12 lbs. of brass. Look up my answer to G. T. M (Vol. I., page 622). If you had stated in your query whether you wanted a wind furnace or blast furnace, it would have been much easier to answer you. In the reference I have given you above, I described both kinds. The dimensions required are about 2 ft. 6 in. high, 16 in. wide, and 16 in. deep. Perhaps your best plan will be to make it of sheet-iron, bound together by two bands up each side of hoop-iron riveted to the outer case, and to line it inside with fire-clay 1½ in. or 2 in. thick; the chimney may be of sheet-iron stove pipe, about 3 in. diameter, let in at the back. It will rapidly wear out near the furnace, and for about a couple of feet wrought-iron tube would be better, and sheet-iron above that. The top of the furnace may be made of sheet-iron, bent down about 2 in. all round in the form of a box, and filled up with fire-clay. Rivet a handle on to move it by. At the ground level in the front of the furnace cut out a hole, say, 6 in. by 3 in., and 9 in. above that cut another hole, 6 in. by 3 in. At a little below the level of the upper hole and inside rivet two angle irons both at back and front of furnace. These project through the fire-clay and support the fire-grate. The upper hole is for clinkering, and the lower hole for ashes, and to regulate the draught. The holes may be stopped with a brick, or tile, or a door attached to each. The furnace is stoked from the top, and the crucible inserted there also. To prevent the wind cooling down the bottom of the crucible, put a small round tile on the bars to stand the crucible on. During the first heating of the furnace, begin very gently with paper and wood, and allow to cool down, and fill up the cracks with fire-clay; then begin again, but increase the temperature, and fill cracks again. Whenever a crack appears fill it with fire-clay, and allow the furnace to die out of its own accord, so as to cool down slowly. I am afraid the length of pipe required would be very unsightly out of doors, and if you are in a crowded neighbourhood someone will knock it down for you, unless you carry it right up the side of the house as high as the chimney. The best plan would be to carry it into a chimney-stack, and block up the opening to the fire-place, so as to bring the draught right through the furnace."

### V.—BRIEF ACKNOWLEDGMENTS.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—W. P. & Co. (*East Greenwich*); W. B. (*Staffordshire*); J. # AMATEUR PHOTOGRAPHY.

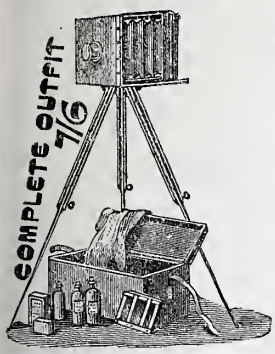
*AN EXCELLENT OPPORTUNITY FOR BEGINNERS.*



In making their Cheap Photographic Sets for Boys, and Beginners whose means are limited, J. H. SKINNER & CO. have striven to reach the maximum of efficiency, combined with the minimum of cost. This they claim to have now attained by using the best machinery wherever practicable, and by selling them at a small profit they are able to place in the market their **Improved Eclipse Cameras and Outfits**, which for quality and price combined defy successful competition. Every set guaranteed perfect, and if found otherwise on receipt will be exchanged or money refunded on return of goods.

**THE IMPROVED ECLIPSE CAMERA SET, price 3s. 6d.,**

Consists of a full ¼-plate sliding bellows Camera (taking pictures up to 4¼ in. by 3¼ in.), made of solid mahogany, polished, fitted with a good double convex, brass-mounted lens, improved dark slide, light-proof; focussing-screen, improved focussing arrangement, packet of dry plates, developing and fixing solutions, and full instructions, enabling any amateur to take a good Photograph. Price **3s. 6d.**; or securely packed by Parcels Post, **4s.**

**7s. 6d. COMPLETE PHOTOGRAPHIC OUTFITS. 7s. 6d.**

Comprising ECLIPSE CAMERA SET, as above: also PHOTOGRAPHIC PRINTING APPARATUS, consisting of hardwood printing frame, with brass spring back, sensitised albuminised paper, gold toning solution, fixing solution, glass rods, cards for mounting, with complete instructions. Also hardwood folding tripod stand and focussing cloth. Price **7s. 6d.**; securely packed, post free, **8s. 6d.** If packed in portable wood case, with hinged lid and leather strap, as in Illustration, **9d.** extra. Every set is carefully examined before being sent out, and guaranteed to be in working order. N.B.—If Apparatus does not give satisfaction, and is returned uninjured within three days of receipt, we guarantee to refund purchase-money.

**THE STANLEY OUTFIT, price 10s. 6d.; by Parcels Post, 11s. 6d.**

This set is precisely the same as the 7s. 6d. Outfit, except that it includes a better Camera, with folding tailboard, a double dark slide, and is sent out packed in hardwood box, with hinged lid and leather strap, without extra charge.

**The Marvel, Norfolk, or Compacta ¼-plate Camera Sets,** price **£1 1s.** each; or by Parcels Post, **1s.** extra.

These sets consist of a superior ¼-plate Camera, with hinged focussing screen, will take horizontal or vertical pictures, mahogany double dark slide, superior achromatic lens in sliding brass mount; also polished hardwood folding tripod.

For better sets, see our Photographic Catalogue, price **2d.**, post free.

***A Wholesale Dealer's Stock-in-Trade at about Half-Price.***

J. H. S. & CO. having purchased from the Trustee the Stock-in-Trade of Mr. J. Methersill, of 6, Southampton Row, and 60, Holloway Road, London, at a large reduction off cost price, are offering it at a little more than half ordinary prices. Send for List, post free on application.

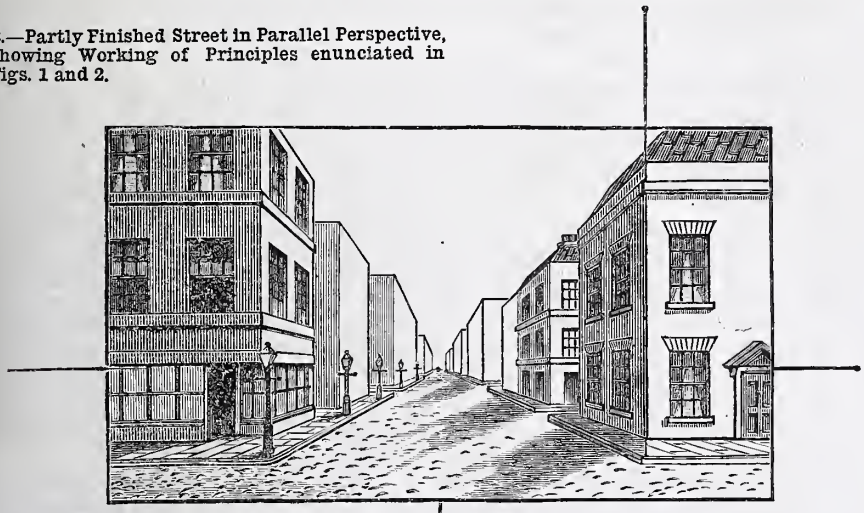
## An Illustrated Magazine of Practice and Theory

FOR ALL WORKMEN, PROFESSIONAL AND AMATEUR.

[*All Rights reserved.*]

VOL. III.—No. 131.] SATURDAY, SEPTEMBER 19, 1891. [PRICE ONE PENNY.

Fig. 3.—Partly Finished Street in Parallel Perspective, showing Working of Principles enunciated in Figs. 1 and 2.



## STAGE PERSPECTIVE.

BY WILLIAM CORBOULD.

### PARALLEL PERSPECTIVE.

IT must be understood by the would-be scenic artist that it is indispensable that he should thoroughly understand the art of perspective. Although a rather dry study, a little patience and trouble will soon simplify the matter; by working out the rules here laid down a few times the student will find the subject prove easy enough. No drawing would be correct unless the principles now to be laid down, and which may be termed the Grammar of Art, be thoroughly mastered. Do not let these words frighten any beginner, because he will find the rules few and simple.

The most important point I wish to impress upon the learner is the names of the different lines, points, etc.; without their use no correct perspective could be obtained. No matter how well a scene may be painted, defective perspective would spoil the whole.

I now direct attention to the following points and lines, which are shown in Fig. 1:—A A′, the horizontal line; B, the point of sight, or vanishing point; C, D, measuring points; E, sight or station point. There are only two rules of perspective in straight lines—parallel oblique or angular—which I will now try to explain as easily as possible by the aid of diagrams.

Fig. 1.—This plate represents the horizontal line, point of sight and vanishing points, and points of measurement—that is to say, the only lines required to work out a scene

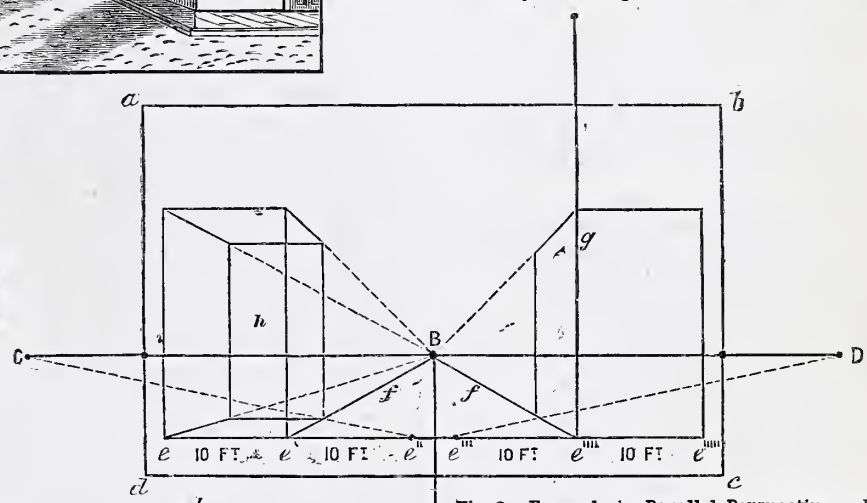


Fig. 2.—Example in Parallel Perspective—*a b c d*, Cloth; C D, Horizontal Line, C and D being also Measuring Points; B, Point of Sight; E, Station Point; *e e⁗′*, Base Line; *e′*, *e″*, *e‴*, *e⁗*, Points of Division; *f*, *f*, Lines to Vanishing Point, B; *g*, Corner Line of Block; *h*, Block.

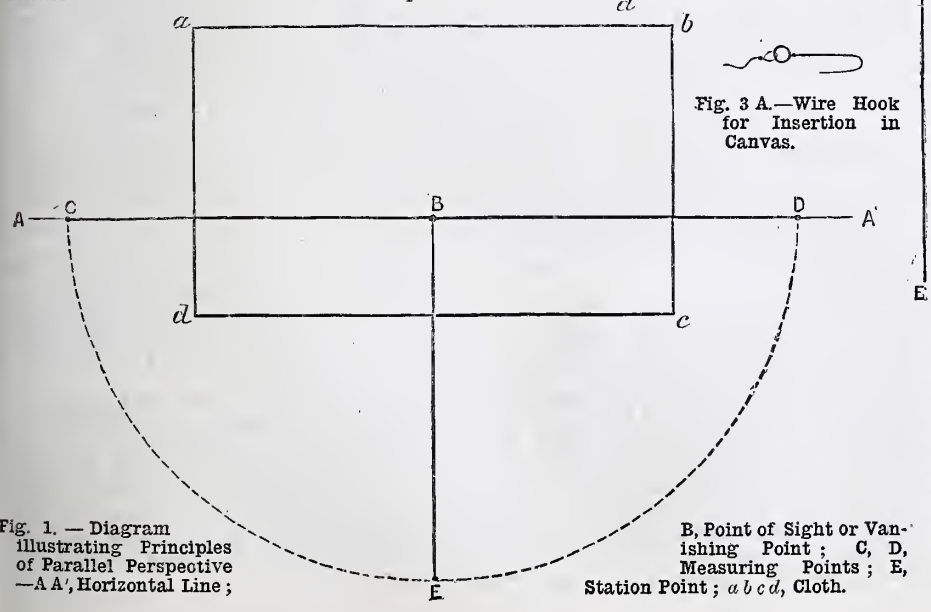

Fig. 1. — Diagram illustrating Principles of Parallel Perspective —A A′, Horizontal Line; B, Point of Sight or Vanishing Point; C, D, Measuring Points; E, Station Point; *a b c d*, Cloth.

Fig. 3 A.—Wire Hook for Insertion in Canvas.

in parallel perspective. The rectangle, *a b c d*, shows the size of the cloth or scene.

A A′ is the horizontal line. Supposing we were standing on the sea-shore: that line which divides the water from the sky is the horizontal line. If the student were to walk up from the shore to the top of some very high cliffs, this line would be found to rise with him, and still be opposite his eyes. We must bear this in mind, because in painting a seascape or a landscape, the horizontal line must rise according to the height of the foreground represented. If we were to go up in a balloon we should find the horizontal line still opposite our eyes, the balloon hanging, as it were, in a huge bowl. Supposing the scene was a mountain pass, three or four thousand feet above sea level, but we were looking out to

sea, the horizontal line would be two-thirds up the scene, or thereabouts. On the other hand, if the reader were painting a scene from the sea-shore, the line would hardly be more than a fourth.

It is always best in stage perspective to keep the horizontal line as low as possible, taking into consideration that some of the audience are sitting below as well as above the horizontal line.

The point of sight on this line would be the spot where all the lines receding from the eye would fall. In Fig. 1 this point is at B on the horizontal line, A A'. This constitutes the rule, "parallel or linear perspective." The points C and D would be the measuring points. All lines above and below the horizontal line must fall into the point of sight, B (Fig. 1).

We will suppose that Fig. 2 represents a road running straight up the plate, with blocks on each side which might represent buildings, such as a street: *a b c d* is the cloth or scene, C D the horizontal line, E showing how far the eye is supposed to be from the picture.

We may determine this by dividing the horizontal line in halves. One-half would be the distance to point E, or by striking a half-circle from E to the horizontal line it would intersect this line at C and D, which would be the points of measurement (Fig. 1).

The base line, *e e''''*, may be marked off into parts of, say, 10 ft. from the dots *e* to *e'*, *e'* to *e''*, etc.—that is, the blocks would be 10 ft. square. The front of the block would be parallel with the horizontal line. A line drawn from the next point, marking another 10 ft. to the points of measurement, C, D, would give the perspective size of the square where it crossed the ground-line of the building, *f f*. This is where the second perpendicular line would rise. *g* shows the block in perspective if it were framed and glazed.

Fig. 3 represents a partly finished street scene, to show the working out of the first and second figures, completing the first lesson in "parallel or linear perspective."

It will be seen here that the fronts of the houses facing the spectator—that is, the lines of the doors, windows, base, and tops of the houses, as well as the pavement—are parallel with the horizontal line. All lines of both sides of the street will be seen to fall into the point of sight, B (Fig. 2). The lamps come under the same rule, as will be seen if we take a line from the front lamp to the last. I hope this will be explicit enough for the beginner, who with a little practice will soon master this first rule in perspective.

We now come to the use of the horizontal and perpendicular lines (page 640, Vol. II., No. 92).

If one were going to draw a picture or scene on paper, the T-square and ruler would do for the purpose; but it is very different when drawing on a large scale, such as 15 ft., 30 ft., or more. It is obvious that lines would have to be used.

As I have explained before, one should have a plumb-bob attached to it for the perpendicular lines; the first one is represented at *g* (Fig. 2). If we hang this straight down, leaving the bob to steady itself when so hanging, dot here and there exactly behind the line; then take the straight-edge, and by connecting the dots make a straight line. All other perpendicular lines can be measured from this one, always having the line to correct from.

The other line should have a piece of stout wire bent as shown in Fig. 3A, the point to be sharp, so that the student may be able to insert it easily into the canvas. This would be the horizontal line.

When the height of the horizontal line is decided on, place a dot at each side of the cloth denoting the height; hook the horizontal line in at one dot; take a piece of charcoal and rub the line with it; cover the other dot with the line, and pull it tightly. With the other hand draw the line away from the cloth and let it go smartly back again: this will give the first or horizontal line—of course, to be covered with vandyke brown and dusted off.

## NEW COVERINGS FOR OLD BOOKS.

BY H. J. L. J. MASSÉ.

GLAZED LINEN AS COVERING—VEGETABLE PARCHMENT—ITS DISADVANTAGES—TREATMENT OF BOOK IN BOARDS—LOOSE PAGES—EDGES—CONCEALING ADVERTISEMENTS, ETC.—COVERING WITH PARCHMENT—END PAPERS—FINISHING COVER WITH RULED LINES, ETC.—COST OF HOME BINDING.

IN one of the earlier numbers of WORK I was much interested in reading about the home manufacture of portfolios for the preservation of loose papers and the like. For special purposes, no doubt fancy stuffs are very appropriate, but they require to be very carefully handled and affixed to the strawboard or cardboard foundation that is underneath. As a boy at school, I used to furbish up my school books when they became very shabby with a covering of brown holland pasted on with very strong paste, in which a small piece of glue had been dissolved. This plan had one very great disadvantage: viz., that the brown holland soon became very dirty, and I soon took to covering the sides with glazed lining. Somehow, I always used the green kind, as being neither too gaudy nor too dull, having previously covered the backs with very stiff glazed brown paper. Of course, the glaze on the lining partly disappeared after being pasted; but I used to varnish the cover with shellac dissolved in methylated spirits with good results.

Sometimes, in later years, I have used the material sold as vegetable parchment, but it is really more suitable for loose removable covers than for those that are meant to be permanent. It is a serviceable stuff for putting a strong back to songs and loose sheet music, and its dull colour can be easily varied by pasting a thin slip of coloured paper underneath. The coloured slip, if bright enough, will show through, and give a pleasing tint to the vegetable parchment; and by using different-coloured papers for the different classes of music a ready means of distinguishing between them is afforded. My only objection to the vegetable parchment is that it is rather intractable under the paste-brush, gets hard, and has a tendency to crack if kept in a dry place.

The other day, having a few spare moments at my disposal, I resolved to remove an eyesore from one of my bookshelves, in the shape of some "yellow backs," by covering them. They were standard novels, by the way, that had been picked up at odd times at half price, or less, at the bookstalls. Now, the binding of these cheap "yellow backs" varies very much. Sometimes the books come to pieces in the very first reading, while sometimes they endure a considerable amount of really heavy wear and tear—mine, luckily, were in good repair, with the exception of a corner or so and a couple of loose pages. The loose pages I secured with a stitch or two, and the corners were strengthened with a little gum. I will deal with one book as a type of the whole batch. One of the edges had been stamped "Reduced to 1s. 2d.," in the so-called indelible violet ink—I say "so-called," because its indelibility is not always to be trusted. By exposing the "indelible" inscription to the sunlight, it faded a little, and to remove it entirely, a gentle rubbing with No. 00 glass-paper was required, the book meanwhile being held in a hand-press, or clamp, made of two pieces of 1½ in. oak, each 16 in. by 8 in., with a ¾ in. hand-screw in each corner. Next, after blowing away the paper dust thus caused, I brushed the edges over with red aniline ink, taking care to squeeze the book extra tightly in the press, and to avoid leaving any excess of ink at the corners, and after an hour a second coat of ink gave the required depth of colour. When this ink was quite dry I cut a piece of demy paper, like that used by chemists for wrapping purposes, about 1 in. larger each way than the book, and pasting it thinly, covered the back and sides of the book, with the object of hiding the illustration and the advertisements of pills and other articles from view, and put the book, with two layers of clean blotting-paper inside and outside its two covers, into a copying-press to dry. A little practice will soon enable anyone to cover the corners neatly. I should advise everyone to try his hand first on a few waste strips of cardboard.

When the demy paper was quite dry, the book already looked quite respectable, with its clean white cover and brand-new red edges. Next I cut a piece of parchment a little larger than the white demy used above, and pasting it well backwards and forwards till it could absorb no more paste, and giving an extra brush along the edges to finish up with, I put the parchment over the white demy and put the book back in the press, with dry, clean blotting-paper as before. When this was *quite* dry—it must be quite dry, or the book would warp unpleasantly—I put in some suitable fancy end papers which I had got from the city house of Messrs. Marlborough, Pewtress & Co.

This finished the inside of the book. To finish the outside, I ruled a red ink line all round the front cover, about ⅛ in. from the edge, and double lines, about 1¼ in. apart, diagonally from the bottom left-hand corner to the top right-hand corner of the cover. This space was filled with the name of the book engrossed with red ink in Old English capitals, and the name was also written in the same style along the back.

The book, when finished, looked extremely well, especially considering the outlay—which was well under 4d.—and put its late companions to the blush.

Bookbinding technicalities have been avoided, as my wish was not to deter anybody who would like to furbish up any stray books without the expense of sending them to be bound, but who would be disheartened by any strange terms.

This article is written from no wish to deter those who seek to do better work in bookbinding from making a trial, but from a desire to show what can be done with very little expense, if only the attempt be honestly made and persevered with. Further, it is a pleasant and profitable way of using and utilising a little spare time.

## HOW TO MAKE A QUARTER HORSE-POWER STEAM ENGINE.

BY F. A. M.

### The Bed-plate—The Cross-head and Guides—The Fly-wheel.

The Four Surfaces of the Bed-plate, and how to bring them True—Screwing the Cylinder to the Bed—The Cross-head Pin, and how to Bore the Hole for it—Chucking the Cross-head—Securing the Piston-rod to Cross-head—Fitting the Cross-head and Guide-bars—How the Connecting-rod acts on the Guide—Making the Cross-head Pin and Boring the Oil Channels—Chucking the Fly-wheel, Boring it, and Slotting the Key-way.

Examine the bed-plate casting and the views of it (Figs. 4, 5, 8, pp. 260, 328), when it will be seen that there are four surfaces to get up true. First, the end surface (1) against which the cylinder is bolted; second, the large facing in the middle on which the slipper-guide works (2); third and fourth, the two smaller facings on which the crank-shaft bearings are bolted (3, 4). The three last mentioned are all in one plane, and, though not necessary, it will be most convenient to have them planed. In fitting or getting up these parts, we must attend to two things: first, it is essential that the first surface against which the cylinder beds should be absolutely at right angles to the other three, or the slipper-guide cannot work without bending the piston-rod, and the rod must point fairly down the middle of the bed; secondly, the recess into which the cylinder cover fits must place the cylinder at the correct height above the three last surfaces; this height is given in Fig. 8: $1\frac{3}{4}$ in. Probably the correct way to do this would be to mount the bed upon the saddle of a lathe, so that the line of the lathe centres shall coincide with the centre line of the cylinder, then a boring-bar would be used both to face the end surface and to bore out the hole in it. We will not, however, propose to make more cutters for our bar, since there is another way which will do very well. If the three level surfaces are not planed, these had better be filed up fairly true, first of all. Get a spirit-level, and, laying it on the three surfaces, pack up with slips of wood, tin, etc., under the bed-plate as it lies on the bench, until the three surfaces come as level as possible; now you can file them up, keeping them in one level plane by trying them alternately with level and surface-plate. The bed-plate had better be screwed down on your bench by wood screws passing through the three lugs. The three flat surfaces being filed or planed, we turn to the end surface, the hole in which requires to fit the cylinder cover. The diameter of the hole is to be $2\frac{1}{4}$ in., and the height of its centre above the plane surfaces, $1\frac{3}{4}$ in.; therefore, the height of its bottom edge above these surfaces will be $\frac{3}{4}$ in. Lay a scribing-block on the second surface, and set its point $\frac{5}{8}$ in. high.; now take a half-round file, and file away at the bottom of the hole till the application of the scribing-block shows it to be $\frac{5}{8}$ in. above the level surfaces. Now turn a short conical mandrel of hard wood (Fig. 38); make it small enough to go into the hole at the smallest end, and at the larger end make it the size the hole ought to be: it may be two or three inches long; rub it all over with chalk, and rub it gently in the hole; take out and file where the chalk appears; continue thus till the cone will go nearly up to the large end, touching also the bottom of the hole, when you file more carefully, and begin to try in the cylinder cover. By this means you can get the cover to fit, without looseness, at the proper height. Fig. 39 is turned in hard wood, and will enable us to file up the first surface at the end of the bed-plate. The neck of Fig. 39 is made $2\frac{1}{4}$ in. diameter, and should fit the hole without shake; the shoulder, A, is turned exactly square and flat; the long shaft is reduced for lightness' sake: it may be 1 in. in diameter, and about 1 ft. 3 in. long, and should be quite parallel. Chalk the surface, A, and put the pin through the hole in the bed-plate; rub A against the end by turning the wood in the hole, and note the direction of the long pin *vertically* and *horizontally*; take out the wood, and file the end surface accordingly. When the eye is satisfied with the direction taken by the pin, measure carefully from underneath the pin to surface 2 at both ends, to see whether the pin is quite level, and from the inner edges of surfaces 3 and 4 to the sides of the end of the pin, to see whether it points fairly down the middle of the bed, passing exactly between them. The surface-plate may be applied to finish the end surface; it need not be scraped, however, but left from a smooth file. We next apply the cylinder cover and cylinder, setting the screw-holes in correspondence while the valve-face is vertical; remove the cylinder without disturbing the cover, scribe through the holes in the cover on to the back of the bed, drill and tap these holes, and now we can screw the cylinder to the bed.

The slipper-guide, or cross-head, and the guide-plates seem to follow naturally, and we will take them next. First finish surface 2 on the bed-plate, on which the guide is to slide, scraping it up true with the help of the surface-plate, as before described. Take next the guide-plates between which the slipper moves; file these top and bottom, bringing them to the same thickness all over; scrape up their lower surfaces and draw-file their upper; square their outer edges and draw-file them; for the chamfered edges make a gauge by filing a notch in a bit of sheet metal with a smooth "three-square" file; use this notch to try the angle of the chamfer, filing to the gauge, and watching the width of the pieces so as to keep them parallel. This chamfered edge must be brought to a true surface by means of the surface-plate and the scraper. Drill three holes for screws in each piece in the positions shown in Fig. 5, and make and fit the four screws seen in the same view, which are used to push them forward into touch with the slipper, but do not bore in the bed the holes by means of which they are held down on to the bed till the slipper is made. Now take the slipper itself, and file up first the sole on which it slides, taking off just enough to make it $1\frac{3}{4}$ in. high to the centre of the bosses. The upper part of this slipper guide is called the cross-head, and the pin which goes through it, and is grasped by the small end of the connecting-rod, the cross-head pin; it is a very important part of the engine, and requires careful workmanship. Look at the view in Fig. 8, and consider what would be the effect on the working of the engine if that pin did not go through *quite* horizontally; look at the plan view in Fig. 5, and suppose for a moment that the hole for the cross-head pin was not *absolutely* at right angles with that for the end of the piston-rod. These points are worth some careful consideration; it is attention to just such points as these that makes the difference between good work and bad, and they are the very things an amateur is most tempted to overlook. The centre lines of the holes in the cross-head, for the piston-rod and for the cross-head pin, must be: first, at right angles; second, in the same plane; third, in a plane parallel to that of the sole of the slipper; fourth, the two planes are to be $1\frac{3}{4}$ in. apart. In the angle-plate we have the very thing to enable us to fulfil these conditions. Taking the fourth condition first: make a little template, like Fig. 40, of sheet iron; bore the hole $\frac{3}{8}$ in. to fit the piston-rod, and let the distance from the centre of this hole to the base be $1\frac{3}{4}$ in. Thread this template on to the piston-rod, and try whether it will touch the guide surface with equal pressure whether the rod be pushed in or drawn out: this will test your work, and show whether the cylinder is really true with surface 2. Now put the angle-plate on the face-plate chuck, drive a bit of wood into the hole in the mandrel, and turn it down to $\frac{3}{8}$ in.; put the template (Fig. 40) on this, and bring up the angle-plate till it touches the base of the template, and fix it there (see Fig. 41). Thus we shall have fixed the upper surface of the angle-plate at exactly the same distance from the lathe centres as the piston-rod of our engine is above surface on which the slipper works. Now remove the template and the bit of wood, and fix the cross-head upon the angle-plate, the dogs holding the sole or slipper down upon the plate, and the bosses for the cross-head pin being centred to run true. Fig. 42 will perhaps make this sufficiently plain. Now face up the boss and bore it through, when the hole will be, of necessity, true with the sole; do not, however, trust to a drill to make this hole straight; a half-round, or D-bit, would do it, but nothing else should be trusted; if, therefore, the workman does not possess a $\frac{3}{8}$ in. D-bit, let him bore with a $\frac{5}{16}$ in. drill, and true out the hole with a fixed tool in the slide-rest, leaving it rather less than $\frac{3}{8}$ in., since it must be cleaned out with a fluted reamer to fit the pin. Having bored this hole, turn a little rod about 4 in. long, or more, that will fit into the hole, being quite parallel its whole length; turn the cross-head one-quarter round upon the sole, and fix it so that the boss of the piston-rod runs true; thread the rod through the hole just bored, and measure very carefully from the ends of this rod to the face-plate chuck, altering the setting of the cross-head until these measurements show by being equal that the hole is parallel with the face of the chuck, and therefore exactly at right angles with the centre of revolution. Now face up the boss for the piston-rod, turning the outside as far as possible; then bore with a $\frac{5}{16}$ in. bit into the first hole, as seen in Fig. 5, and cone out this hole to $\frac{3}{8}$ in. with the fixed tool in the slide-rest, using a very sharp and rather pointed tool, and setting the cutting point at exactly the height of centres. By this method of procedure we ensure the accomplishment of the four conditions before stipulated, and the plan forms a good example, which is very likely to be of use on other occasions. Having prepared the hole for the end of the piston-rod, put the piston and its rod into the lathe once more, and turn the end of the rod to fit the hole, observing the dimensions written along the rod in Fig. 5; drive the cross-head on to the rod, drill a $\frac{1}{8}$ in. hole right through for a pin to hold it on, and put a slightly taper reamer in to enlarge the upper end of the hole.

In an ordinary way there would be a flat key to secure the piston-rod into the cross-head, but this would be a much more

difficult job to accomplish; and, since the piston-rod is of ample strength, it will not pull in two even though half its cross section is cut away by the round pin. Moreover, the pin may be of good steel, hardened and spring-tempered; it will not then shear in two. Also it is quite easy to put a little "draft" on the pin, so as to make it tend to draw the rod into the cross-head; all that is required, after reaming out the hole and fitting the pin, is to put a small rat-tail file into the hole in the piston-rod, and file away a very little at B (Fig. 43), and into the cross-head, and file away a little at A, A—a very little will do it, and the plan often comes in handy.

Having put the cross-head on the rod, driven in the pin securely, and marked the rod so that it may be put in always the same way, rub some marking on the guide surface, and try the working of the cross-head by pulling it up and down whilst the piston and cylinder are in position. Notice whether the sole of the slipper bears all over on the guide surface, or whether the front or back edge is lifted; if so, take the cross-head off the rod and correct the sole with the scraper: it should not require much if our directions have been observed. We have now to file up the slanting edges of the slipper parallel with the piston-rod and with each other, and to the same angle as the guide-bars. Test your work as you proceed by laying the cross-head and two guide-bars in position upon a true surface, as in Fig. 44, and observing whether the guide-bars and piston-rod are all three parallel. (The piston should be taken off the rod, else it will be in the way.) When this is the case, finish filing up the cross-head, elongate the holes in the guide-bars, as shown in Fig. 44, place it and them in position on the guide surface, mark through the holes in the guide-bars on to bed, to give the positions of the six holding-down screws, drill and tap these holes, and put in the screws to hold down the guides and the four others used for advancing them sideways into contact. Now slide the cross-head and piston-rod up and down, the piston being removed and the rod passing through the stuffing-box. Watch whether the chamfered edges of the slipper are in perfect contact with the guide-bars, and correct them till they are. It will take some little time and trouble to do this properly, but it is worth the trouble. The red marking would be rubbed on the guide surface and inside the guide-bars; the cross-head would be rubbed up and down and then pulled out, the piston-rod coming out of the stuffing-box. Thus the chamfer of the slipper can be quickly tried, examined, and corrected, and then put in again. Don't say those fateful words, "It'll do," till the marking shows the chamfered edges and sole of the slipper really touch all over. Then put on the piston, and test once more.

Here it should be understood that the particular form of guide which has been described is suitable for an engine which will run chiefly, if not entirely, in one direction. Every reader who has studied the Introduction should know by looking at Fig. 4 in which direction the engine will run. The eccentric precedes the crank by a little more than a right angle, and therefore the engine wheel, as seen in Fig. 4, will turn round in the same direction as do the hands of a clock.

In the little diagram at Fig. 45, A B represents a piston-rod, B C a connecting-rod, C F a crank, and C D E a crank circle. Now, if the piston be driving forward the crank from C towards D, were there no guide at B for the cross-head, the tendency would be to bend the piston-rod downwards. It is this tendency which is resisted by the broad sole of the slipper-guide in the engine we are making. But let the motion of the crank be continued past D to E, and let the connecting-rod take up the position of the dotted line, B E; now the piston-rod is pulling the crank, yet the side pressure at B is still downwards, and not upwards, as one might have supposed. If, however, the direction in which the engine runs were to be reversed, then the pressure on the guide would be continually in an upward direction, and our guides would require to be modified. As it is, the pressure comes on the broad sole of the slipper, and is received by the solid metal of the bed, the guide-bars merely acting as safeguards.

We may now undertake the cross-head pin, as seen in Fig. 8. This is to be made of mild steel. Take a piece of Bessemer $\frac{5}{8}$ in. diameter, and about $2\frac{1}{4}$ in. long, and bore right through the centre a hole $\frac{3}{32}$ in. in diameter; this is for the oil or grease to pass. Countersink both ends of this hole to fit the lathe centres. The hole must afterwards be plugged up at both ends; or it might be bored not quite through, as shown at Fig. 8; at any rate, the piece must be a little too long at first, so as to allow for removing the countersunk part and squaring up the ends. Take a $\frac{3}{8}$ in. taper fluted reamer, and clean out with it the hole for the pin in the cross-head so that it can be driven in up to $\frac{5}{16}$ in. of the head. While in that position, bore the hole for the little $\frac{1}{8}$ in. set-screw, seen in Fig. 5, opposite the piston-rod, letting the point of the drill cut a little way into the cross-head pin. Take out the pin from the cross-head, tap this hole and fit the set-screw, then drive in the pin again, and fix it so with the set-screw, which must enter the little hole made for its point. Now bore the oil channels, as seen in Fig. 8; first bore with $\frac{3}{32}$ in. drill from the centre of the top of the cross-head right down through the cross-head pin and out at the sole; this will supply oil to the sole of the slipper. Then bore across the bottom of the hole from one side chamfer to the other, as seen in Fig. 8; bore also the two short holes from the top of the cross-head pin to the central hole, which will enable the lubricant to reach the two bearings at the forked end of the connecting-rod. The single lubricator screwed into the top of the vertical hole supplies lubrication to all these five surfaces.

Fig. 42.—Mode of chucking Cross-head. Fig. 43.—Mode of securing Piston-rod into Cross-head. Fig. 44.—How Chamfers on Cross-head are tested for Parallelism. Fig. 45.—Diagram to explain Action of Connecting-rod on Guide. Fig. 46.—Mode of chucking the Fly-wheel.

Fig. 46 shows how the fly-wheel may be mounted on a 10 in. face-plate chuck for boring $\frac{7}{8}$ in. hole for crank-shaft. It is 16 in. in diameter, and if the gap in a 5 in. lathe were 3 in. deep, the wheel could be mounted as shown, the hole bored and slotted for the key, and the boss turned.

Possibly the rim might also be turned, but it would be with difficulty. It is not necessary to have it turned, though it does certainly improve the appearance of the engine, provided it be kept clean and bright. This rim, like the planing of the bed, might well be left to an engineer or to whoever supplies the castings. In Fig. 46, A is the face-plate; three of the arms are grasped by clamps of iron, B, B, B, and under each arm beneath these clamps are three pieces of hard wood which hold the boss of the wheel off the face-plate. When the wheel had been adjusted to run true and the clamp screws firmly fixed, the boss would be turned and the hole bored, first with a small drill, and then with larger ones, till nearly the right size, when it would be finished with a fixed tool in the slide-rest, using a sharp tool and a very light cut, and trying in the hole a bit of $\frac{7}{8}$ in. turned bar, to make quite sure it is turned parallel.

The key-way would be most easily made by slotting in the lathe—*i.e.*, fixing a slotting tool on the slide-rest, holding the work still, and moving the tool into the hole by working the saddle along by the rack. As, however, an amateur may not think it worth while to make a slotting tool for this key-way and that in the boss of the eccentric only, he may do the job by simply marking the position of the key-way by two lines drawn inside the hole by the point of the tool which was used in the slide-rest for finishing the hole. To do this, the work would be held still whilst the lines were drawn by moving the saddle along the bed by means of the rack. This method would ensure that the key-way should be marked out parallel with the hole of the wheel, and then the cutting could be done with the chisel and file. The key-way is not "sunk" in the shaft, as is usual, but bears simply upon a flat filed on the shaft, and therefore it should be rather larger than usual, since it is absolutely essential that it should fit well, and hold the wheel to the shaft without the slightest possibility of turning on it, for this would produce a knock at every stroke; and any slight looseness there might be at first would continually increase. Then make key-way $\frac{3}{8}$ in. wide and $\frac{3}{16}$ in. deep.

# NOTES ON HAND SAWS.

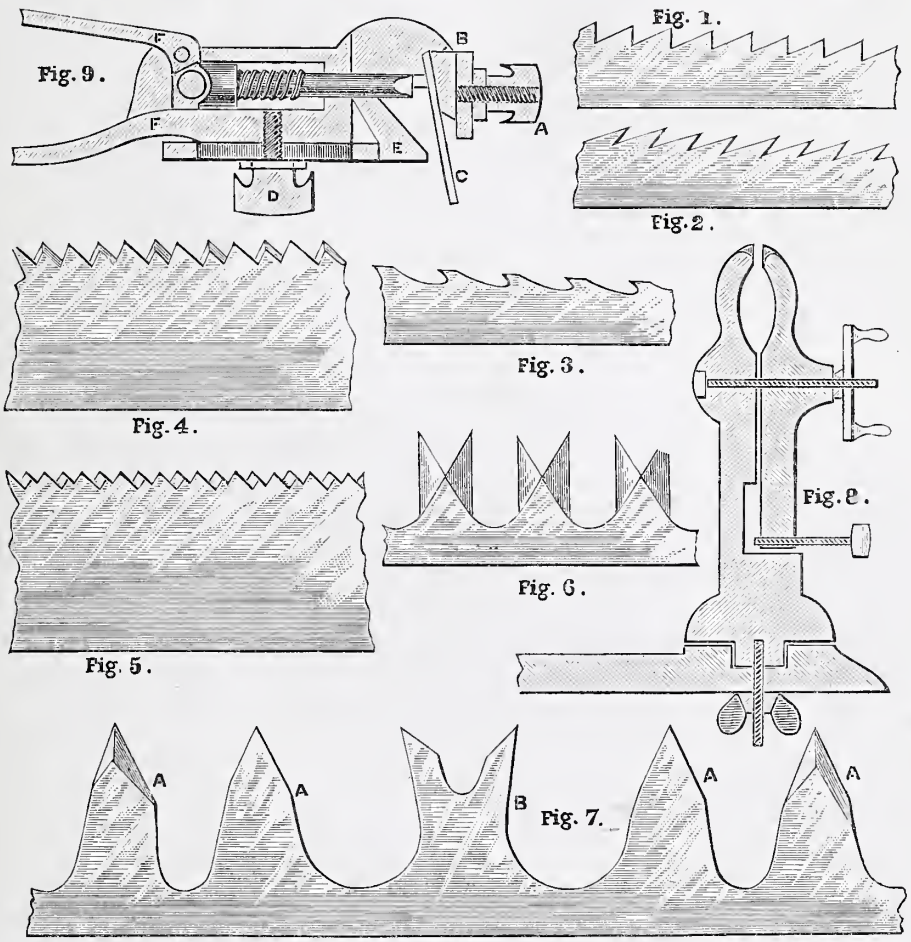
BY M. POWIS BALE, M.INST.M.E., A.M.INST.C.E.

*Author of "Woodworking Machinery," "Saw Mills: their Arrangement and Management," "A Handbook for Steam Users," etc.*

SELECTION OF A HAND SAW—SAW SHARPENING—VICE FOR BENCH—VICE VIBRATION—FORMS OF TEETH OF SAWS—ACTION OF RIP SAW—BEVELS OF TEETH—SETTING SAWS—SPRING-SETTING—HAMMER-SETTING.

On no point connected with wood conversion do opinions differ so much as in what is the best shape and cutting angle of saw teeth, and the proper method of sharpening them. This is, perhaps, more particularly the case with power-driven circular and mill-web saws, and is proved by the fact that there are at least one hundred varieties of teeth in use; but it applies, to a certain extent, to hand saws. The few notes given here, I trust, may be of some service, and I shall not be accused of egotism as I simply give an opinion and nothing more.

*Selection of a Hand Saw.*—In selecting a saw, for whatever purpose, do not be tempted by a low first cost, as this is no criterion as to its ultimate cheapness. What is required is a blade made of the very best quality of steel, combining, as far as may be, flexibility and toughness with a sufficient degree of hardness to allow of the steel carrying a good cutting edge. A saw bearing the name of a maker of repute should, and usually does, give satisfaction; but as a great number of very inferior ones are sold, some of the points to be desired in a good one, with a few hints on testing, may not be out of place. In selecting a saw, see first that the handle is comfortable to the grasp and made out of thoroughly seasoned wood. Beech handles, with countersunk rivets, are preferred by many. The blade of the saw should be of as thin a gauge and as narrow as the nature of the work it has to do will permit. A thin and narrow saw wastes less wood and will work with less friction than a thick and wide one, consequently it requires less power to drive it; at the same time, it will usually be found that the steel used in thin blades is of finer quality than in thick Care must be taken, however, that too thin a blade is not selected, and that the saw is stiff in work, as, should it "buckle," it may give a great deal of trouble. Bend the blade of the saw thoroughly, and see that it has a good flexible spring, and will fly back to its original position without marking or buckling the blade. Examine the blade carefully in a bright light, and see that it has been properly hammered and ground. See that it is carefully set and sharpened, and not too soft in temper, or it will rapidly dull and require frequent re-sharpening. If the saw has been "hammer"-set—in contradistinction to "spring"-set—without fracture to the teeth, it is a very fair test as to the quality of the steel. The blade should ring clearly when struck with the finger, and when sprung over by hand it should not jar in the handle. Finally, if possible, try the saw on a piece of difficult cutting wood, and see how it behaves: if it cuts fast and clean with a moderate expenditure of power, it is what you require. Increment teeth have of late come more into use—that is, the point of the saw is arranged with finer teeth than the heel—and are liked by many operators, as the fine teeth commence the cut smoothly, and the coarse teeth prevent the saw clogging.



Figs. 1, 2.—Saw Teeth that may be filed square across. Fig. 3.—Saw Teeth with Rounded Gullet. Fig. 4.—Cross-cut Teeth for Soft Wood. Fig. 5.—Ditto for Hard Wood. Fig. 6.—M-shaped Teeth. Fig. 7.—Saw for cross-cutting Logs. Fig. 8.—Bench Vice to hold Saw during Setting. Fig. 9.—Patent Saw set for bending Saw Teeth.

*Saw Sharpening.*—Having selected our saw, now comes the question of sharpening it. This is usually done with a three-sided saw-file. These are generally cut in three degrees of fineness. A second-cut or smooth-cut file is best for sharpening a hand saw. Select a file of the very best quality, about 10 in. long, and see that the teeth are cut perfectly even, and the colour of the file is uniform. If it is of a whitey-grey colour throughout, it shows that the temper is uniform; but if it is mottled, you may conclude that the temper is uneven.

To sharpen the saw, clamp it in a saw vice. The clamps should be of hard wood of about 3 in. deep by 1 in. in thickness. The upper edges of the wood should be chamfered off considerably, so as to allow of the file being held at an angle. The saw blade should project slightly above the top of the clamp, but not sufficiently far to allow of any vibration on it, or it will very soon strip the teeth of the file, and rapidly wear it out. The clamps and saw can be held between the jaws of the bench screw. Several excellent saw vices, well adapted for amateurs, are now made which spring the saw slightly, and so prevent vibration of the blade when filing. Vice vibration may be reduced considerably by fitting thick strips of indiarubber between the jaws.

Fig. 8 gives a sectional view of a very simple form of vice for fixing to work-table or bench. It is very handy, and will be found well adapted for amateur and general use. Its action will be readily understood from the illustration.

We will first consider briefly the sharpening of a hand rip saw. The forms of teeth most generally in use are shown in Figs. 1, 2, and 3. Fig. 1 is, perhaps, the most common, and, in my opinion, undoubtedly the worst form of the three; No. 2 a better form; and No. 3 by far the best, although the most troublesome to sharpen. In ripping with the grain of the wood, the saw teeth should act like a series of small chisels, producing minute chips or shavings instead of fine dust; if this latter is produced by a rip saw, it is grinding, not cutting. Correctly speaking, saw teeth should be adapted and modified in shape and set to suit the nature of the wood they have to cut; but as a hand rip saw has usually to do various kinds of duty, all that we can do is to select a tooth that can be used with tolerable success on a considerable variety of woods. The tooth shown in Figs. 1 and 2 is often filed square across, and this will answer fairly well for straight-grained wood; but as cross-grain is constantly met with, I prefer to file the teeth with a slight bevel. After the saw is set, some sharpeners give a bevel to the points of the teeth by holding the file at right angles to the saw. Owing to the rounded gullet, the teeth of Fig. 3 are much less liable to crack at the root than Figs. 1 and 2, which have an angular gullet. M-shaped teeth, similar to Fig. 6, are now largely used, chiefly in America. They have cutting edges both back and front, and will cut in both directions. They are usually bevelled and set alternately, and, if kept in good order, will cut rapidly.

The action of a saw when used for ripping or cutting with the fibres of the wood is entirely different from one used for cross-cutting or severing the fibres of the wood transversely. The shape of the teeth and the method of sharpening should, therefore, be entirely different. In the case of a ripping saw, the action of the saw is chiefly a splitting one,* the saw teeth acting like a series of small wedges or chisels driven into and separating the longitudinal fibres of the wood; whilst with cross-cutting saws, the fibre of the wood has to be severed across the grain, and is comparatively unyielding, and the teeth of the saw meet with much more resistance; it is therefore found necessary to make the teeth considerably more upright and more acute or lancet-shaped in their form than for cutting with the grain. Fig. 4 represents cross-cut teeth, adapted for soft wood, and Fig. 5 teeth for hard wood; the teeth for medium wood being at an angle about midway between the two. The faces of the teeth should be sharpened to a keen edge, so that in work they may have a direct cutting action similar to a series of knives. For soft wood the teeth should have a full set, and care should be taken that the teeth are made of sufficient depth to allow of an easy clearance for the sawdust. About eight or nine teeth to the inch can be recommended for general purposes. For hard wood there should be about ten teeth to the inch, and the back of the teeth filed square. Do not file all the teeth from one side, but file the front of all teeth set from you, and the back of those set towards you. Some sawyers recommend going over a saw several times to get the best results. The last teeth of cross-cut saws should be rounded at the points to prevent tearing when entering a cut.

One of the great difficulties found in hand sharpening is to get the bevels of the teeth exactly alike. A number of mechanical arrangements to guide the saw and effect this object have been tried with more or less success. In the best with which I am acquainted there is a circular casting, divided and indexed from its centre each way, giving bevels for each side of the saw, or square across. The file is fitted into a guide, and is held by a set-screw. The index shows the pitch at which the file is set, and a rod passes through holes in a graduating ring and guides the file. The frame upon which the ring is held slides in grooves cut on each side of the vice in which the saw is fixed; a table connected with the guide is arranged and indexed so as to give the required bevel and pitch for the kind of saw to be filed, and it is only necessary to set the ring for the bevel, and the indicator for the pitch, and the apparatus is ready for use. As the filing is proceeded with from tooth to tooth, the frame follows, giving the same bevel, pitch, and size to each tooth on one side of the saw the same as on the other, thus leaving the saw, when finished filing, with the teeth all uniform in size, pitch, and bevel, so that each tooth will do its share of cutting equally with the others, thus turning out more and better quality of work with a less expenditure of power.

After a saw has been sharpened, it should be carefully jointed, or, in other words, it should be laid flat on its side and the teeth rubbed down with a whetstone or smooth file to remove any feather edge that may be left by the file in sharpening. This gives a larger and better cutting edge to the saw. If the points of the teeth only are allowed to do the work, the action is a scratching and not a cutting one.

For cross-cutting logs with a double-hand saw, I can recommend a saw with teeth similar to Fig. 7, instead of ordinary cross-cut teeth, as it is much quicker and cleaner in cutting. These saws are of American origin, where they are now largely used. The cutting is done by the teeth marked A, and the tooth marked B acts as a clearer; this latter is filed about $\frac{1}{32}$ in. shorter than the scorer teeth. The teeth are often formed on both edges of the blade, and when one set are worn down, they are knocked off, and the other edge of the blade used. The saw is made slightly curved, and the handles reversible. Fourteen gauge steel is used. From experience I can say this form of saw is rapid and easy to work, and does not bind in the cut; at the same time comparatively little set is required. It will cut well both hard and soft wood.

*Setting Saws.*—After the saw is filed, and all the teeth made as uniform as possible in shape, length, and gullet, comes the important operation of setting the teeth so as to afford a ready clearance for the sawdust. This is apparently a simple operation; but to secure absolute uniformity in setting by the use of the common saw-set is not by any means easy, consequently greater power is required to work the saw. The longest teeth having the greatest set, are rapidly worn down, and the work turned out is scored and rough. At the same time, the saw will run from the line to the side of the saw on which there is most set. If a saw is properly and uniformly set, the teeth should form an angular groove one with the other when held up to the light and looked at from point to heel. The amount of set necessary to allow an easy motion to the saw without pinching it or allowing it to rattle will vary according to the nature of the wood—clinging and stringy fibred woods requiring more set than hard woods; but no more set should be given to a saw than is absolutely required, as the more the set the greater the power required to work, and the greater the loss of wood.

Two kinds of setting are used for hand saws—viz., spring-setting and hammer-setting. In the former the teeth are bent from the line by a saw set; in the latter they are set over by a blow from a hammer.

In using spring-set, it is necessary to slightly over-set the saw, to compensate for the tendency of the teeth, especially when worn and dull, to spring back to their original position. Several capital contrivances are now made for spring-setting, so arranged that all the teeth can be readily set to one line, and when the instrument is fixed it is impossible to overset a tooth; and should the saw be found to bind at any particular point, the teeth can, with this contrivance, be set into line, and any excessive friction reduced. I illustrate herewith such a set (patent) by Fig. 9, which is adapted for setting either hand, circular, mill, or band saws. Its operation will be readily understood from the sketch and the following directions for use: Hold the saw with the teeth upwards; adjust the die, B, by means of the screw, A, in the end of the set, so as to have the angle on the die, B, come near the base of the tooth on a fine saw; on a coarse saw, have the angle of the die strike the tooth about two-thirds down from the point. Set the guard, E, on the underside of the set forward to about $\frac{3}{16}$ in. from the die, B; then let the set hang loose on the saw. When thus held, the space between the tooth and the die shows the amount of set you will be giving the saw. To increase the set, move the guard, E, still closer to the die; to decrease the set, move the guard back.

Saws set by the blow of a hammer or punch are apt to be more irregular than spring-set saws; the operation should, therefore, be very carefully done, and the teeth constantly tried with a gauge or straight-edge, so that all the teeth should be exactly in line. Hammer or swage-set teeth will stand well up to their work in cross-grained and knotty wood, whilst spring-set teeth are more inclined to dodge the knots. I have seen saws working with part of the teeth spring-set and part hammer-set, but the difficulty of keeping them exactly uniform neutralises any advantages the plan may possess.

Before attempting to set and sharpen his own saws for actual work, the amateur should practise on an old saw which he cannot possibly spoil.

* See "Saw Mills: Their Arrangement and Management" (M. Powis Bale).

## MY FIDDLE-CASE: HOW I MADE IT.

BY O. B.

PROFESSIONAL AND AMATEUR WORK CONTRASTED—PATTERN OF CASE—MATERIAL—JOINING UP BOX—FORMATION OF LID—LOCK, HANDLE, ETC. FITTINGS—LINING.

IF I were asked to define man, I would say he is a creature sensible of increasing needs. No sooner has he satisfied a want than he feels possessed of a capacity all the larger for having accomplished his object. This is the basis of all human progress, and of this feeling all men are more or less conscious.

These reflections have been occasioned this wise. Having made a music-stand, I soon began to feel that I was sadly in want of a fiddle-box. It is true I had a box, but the more I looked at it the more I became dissatisfied; and for this reason. Nearly thirty years ago I became possessed of a very fine old instrument. I gave a cabinet-maker an order to measure the fiddle for a suit of mahogany and baize, which in due time came to hand with the "little bill;" but one may imagine my annoyance at finding that to reduce the size of the box he had actually shortened the bow to the extent of two inches.

And here I am reminded of a circumstance which came under my notice a little while ago. Being in a town at a distance from my residence, I was accosted by a stranger who had seen my name announced. He wanted to know if my name had not appeared in WORK, to which I pleaded guilty; whereupon a conversation ensued as to the merits of the paper. His opinion was that many of the articles were very amateurish—for example, one on a music-stand. I maintained that one advantage of WORK was that amateurs wrote for amateurs as well as professionals for professionals, and that having faced difficulties, they were better able to explain them than the professional workman, who, from his frequent repetitions and mechanical operations, had long since failed to notice the difficulties. And further: it must have been observed many times over that when a professional gives instruction in his art, either from stronger professional jealousy or otherwise, some essential—some pinch of salt—is left out, so that the explanation is much like that of a professional conjurer: "'You don't see exactly, you know." But, granted that an amateur does his work amateurish, what then? Do not professionals make blunders that an amateur would be ashamed of? What amateur would make a box to fit a fiddle and then cut a grand old bow to fit the box? Well, it was for this reason I discovered I needed a new one; for the young people had to carry the bow in paper when they went out with their fiddle; and besides, the box itself was of such a shape that some vulgar little boy cried out, "Heigh! see that lass: she has got a coffin!" and truly, it only needed the upper corners to be taken off to be the exact pattern of a box for "mortal remains;" but then, it was made by a professional, so there is *some* comfort in that.

The pattern and the material cost me some thought. There was the ordinary round-ended case, but to make a presentable one of this pattern, even if I availed myself of a Dutch cheese-box to provide the circular ends, did not seem very easy. Then there was the coffin pattern, but I could not contemplate that with any pleasure. There was only one that I could think of, known, I believe, as the French pattern. This seemed to be the best. Having a good stock of walnut-wood by me for fretwork, I considered this to be most suitable. Shooting one edge true, I measured and marked off two pieces for the sides (as Fig. 1), the long edge 2 ft. 8 in., short edge, 1 ft. 11 in., and 10 in. wide. These were carefully cleaned up. To make the ends the same angle, they were planed together, and then the ends reversed and planed up again. By this means the ends were got true. Two pieces, $10\frac{3}{4}$ in. by $4\frac{3}{4}$ in., for the ends; one piece, 24 in. by 5 in., for the top; and another, 29 in. by 5 in., for the bottom. The end pieces were made the same width, and one end of each squared off.

How should the box be joined up was a consideration. The wood was thin, so I decided on the following plan:—I cut a $\frac{1}{2}$ in. plank into $\frac{1}{2}$ in. strips, and glued and screwed a strip on the inside edges of the end pieces, which would be joined to the sides, being careful to use such screws as would not come through. When the glue was hard, I carefully squared up the edges. I now had a good $\frac{5}{8}$ in. surface to join the side to, which was done by glue, and three screws driven in from the outside. Before the glue set the work was tried, to see that it was true. The top and bottom of the end

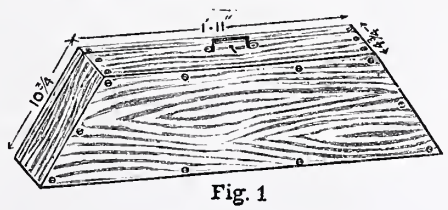


Fig. 1

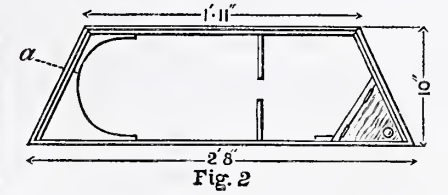

Fig. 2

Fig. 1.—Fiddle-case in Isometrical Perspective.
Fig. 2.—Plan of Case within.

pieces were now planed off level with the sides, and the inside edges of each were lined with strips, to increase the thickness all around. Then the edges were planed and squared up, and care taken that there was no winding on the edges. The top and bottom were now put on with glue and screws, precaution being taken that the screws were put at equal distance by measurement, else they would present an unsightly appearance when the case was completed.

The work was now put on one side to dry and harden, when the screws were withdrawn, and the whole surface was worked up as smooth as possible: first with a fine-set sharp plane, and then with glass-paper. The screw-holes were countersunk, and the screws replaced. The case was now cut in two, leaving a caddy-lid 1 in. deep. The edges were planed true, to make a close joint. On the inside of the deeper half along the top and ends a strip of wood was glued, projecting $\frac{1}{2}$ in., so as to form a rebate for the lid to close over (*a*, Fig. 2). This had to be taken down with a rebate plane, else the lid would be too tight. Blocks had to be glued on the inside of the bottom, to give a foundation to the screws holding the hinges, which, in my case, were ornamental ones fixed to the outside, and not as ordinary butts. A lock and handle were fitted in their place. The inside now received attention. Across one corner, as shown in Fig. 2, a piece of wood was secured by blocks, and a lid hinged, as a receptacle for strings, etc.

At the opposite end a piece of wood was cut with a fret-saw, to fit the end of the instrument. This was glued in its position, and secured with blocks. A piece of stout cardboard was then bent and fastened to the hollow wood with pins; this reached to the bottom. Measuring where the neck of the fiddle would come, a strip of wood was glued across the lower half, with a slot to take the neck. By this means the instrument is kept in its place. A packing-piece was secured from this division, slanting towards the tail, so that the instrument should bed firmly. On this, cotton wadding was laid. The sides and bottom were now lined with velvet. In the lid, on the longer side, two pieces of pine, 3 in. long, were glued, to hold the bow, which is kept in place by small brass buttons. The lid was also lined with velvet.

When the inside was lined, the outside was polished, after which the hinges and handle were replaced, and the case, thus completed, presents an elegant appearance. On the principle that the kitten can go through an opening large enough for the cat, I made my box deep enough to take the highest model fiddle I have, so that a flat model can be taken equally well.

## AN EARLY RISER'S FRIEND.

BY C. MAYNARD WALKER.

ADVANTAGES OF ALARUM—DIMENSIONS—CLOCK PARTS—CASE—PARTS OF APPARATUS—MAKING UP—THINGS THE ALARUM WILL DO—ALTERING CLOCK—MATCH-HOLDER AND AXLE—SPIRIT LAMP—HOLDER FOR STRIKING SURFACE—REFIXING CLOCK MOVEMENT.

How to make an alarum for early risers, which will strike a match, light a lamp, boil water, make tea or coffee, and awaken the sleeper at any required hour. The advantages to be derived from the habit of early rising, whether viewed from the points of obtaining or retaining health, or for the lesser objects of acquiring wealth by devoting more hours to labour, or of riding some particular hobby, are pretty generally admitted; and while it may be true that most persons living in the country practise from choice the laudable habit with a regularity that is perhaps hereditary, and also that thousands are compelled to rise early in order to follow their employment, whether they like it or not, it is equally true that a very respectable minority, who, while recognising the advantages of early rising, fail to acquire the habit, either from a want of strength of purpose, from natural sleepiness, or from some other reason equally powerful to keep them in bed, and who therefore usually "oversleep" themselves—unlike the late Duke of Wellington (the Iron Duke), who is reported to have uttered and acted upon the statement that "when a man turned over, it was time to turn out." The enormous trade in alarum clocks, carried on in this and other countries, is evidence that the class of persons referred to is a very large one; and as, doubtless, many of them are readers of this Magazine, and therefore anxious to carry out some of the excellent suggestions therein, will welcome the instructions here given, which, if carefully carried out, will put them in possession of a faithful servant, which will minister to their comfort by calling them at any desired hour,

and, further, getting the breakfast ready at the same time.

In these instructions it is to be understood that the parts are of such form and of such material as are best suited to be made up by persons capable of doing ordinary soldering with sheet metal, and without the use of expensive tools; therefore, such parts of the apparatus which could be much better made from castings and turned may be with advantage so altered. However that may be, the present plan will answer every purpose.

Fig. 1 represents the complete apparatus, the dimensions being: height, 8 in.; width, 5½ in.; depth, 5½ in. externally, and is taken from a photograph of one in use, and made by the writer. The outer part or case is made of tinplate. The internal fittings are of wire and tin of the simplest kind, so that anyone capable of "jobbing" tin work may undertake the work with every probability of success. The clock part is an ordinary alarum clock, known in the trade as a "Cottage Alarm," and can be bought through any clock dealer, or direct from Messrs. Meyer, Aldersgate Street, E.C., for about 3s. 6d. This will be found a serviceable article. When purchased, it will be in a wooden case, which will of course be dispensed with and put to some other use.

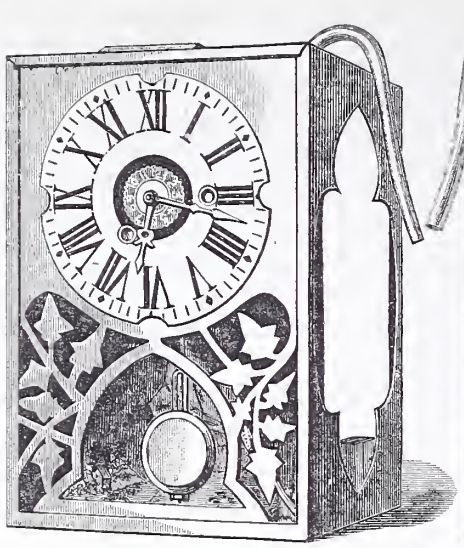

Fig. 1.—Apparatus complete.

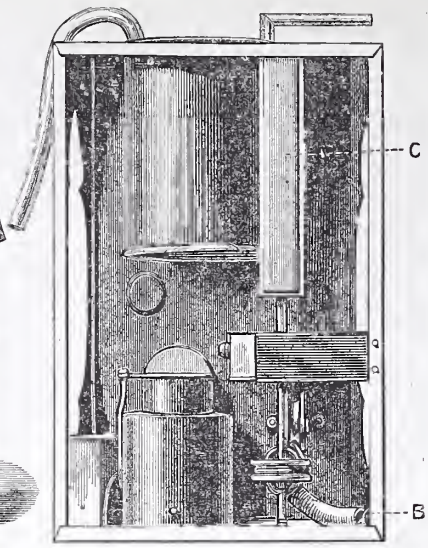

Fig. 2.—Back of ditto; B, Check Spring; C, Angle-piece.

We shall first require to make up the case (Fig. 3), which will need but little explanation beyond pointing out that the edges of the front are turned over on three sides only, the bottom being left to admit of the front sliding into its position; also that the device or cut out at the sides is simply to combine a little ornamentation while strengthening the side. The cutting should be made before the case is made up; also the hole, B, 3 in. in diameter, should be cut. The case is quite open at the back, and from the front a kind of inner case extends 2⅛ in. inside of tin, which will presently form the case proper of the clockwork. In the back of this inner case, at a point 1½ in. from the bottom and 1 in. from left-hand side, is cut an oblong hole, 1⅛ in. deep by ⅜ in. wide. This case should be very neatly made and its sides true to each other, or the finished work will present an awkward appearance. We have now to fit up the mechanism, and it will be best perhaps that, at this point, a description of the general idea should be given. We have an alarm clock, which, in its present form, simply sounds a bell at a given hour. We want to make the clock carry out our purpose, so that, in addition to being awakened, we shall be provided with tea or coffee, ready to hand when the alarm is given. In order to do this, we remove the spring of the alarm, and in its place attach a piece of catgut. Connect this to a piece of mechanism at the back of the case, which will carry and strike a match in such a position that the match will ignite a spirit lamp under a small boiler, the water of which will run out as soon as it boils into a tea or coffee pot, and at the same moment sound a shrill call with a whistle on the boiler. The writer has endeavoured to arrange the parts so that they occupy a comparatively small space, and that the case shall present a fairly ornamental appearance, the front (Fig. 1) being a design cut out of zinc with the fret-saw, and the dial of clock let in behind, the whole sliding up the groove referred to in case (Fig. 3).

The details of the various actions of the interior will now be described. Having made the outer case, we require to make the necessary alteration in the clock. Remove it from the case, and take out the wire holdfast on the alarm side, so as to be able to raise the plate. You can then, with a little care, take out the spring-wheel and spring, cutting the latter clear of the bar to which it is fastened to the clock. Having removed the spring from the wheel, punch out the rivet which held it in its place, and in lieu thereof pass one end of a length of catgut (14 in.) through the hole. Leave about ½ in. of the catgut out, tie a small knot, and restore the wheel to its position in the clock, and fasten up the plate as before. In front of the spring-wheel, at the winding-up pin, will be noticed a peculiar shaped piece of brass, which acts as a stop to the winder, and prevents the work being overwound. We shall require to readjust this later on.

Further down at the bottom of the works will be noticed an escapement in connection with the alarm, having a small weight on a piece of wire, which acts as a bell-hammer. Cut this off with wire-cutting pliers. Also notice attached to this two steel pellets, which, when the alarm runs down, alternately escape, and give the necessary intermittent action of striking the bell. We do not

Fig. 3.—Plan of Top of Case. Fig. 4.—Match-holder and Support (half full size). Fig. 5.—Pulley-wheel (full size), with Wire and Screw. Fig. 6.—Section of Lamp with Sliding Cover pivoted at S. Fig. 7.—Carrier for Friction Surface (full size): the Dotted Lines show where Edge of Metal is turned up. Fig. 8.—Section of Steam Whistle (full size). Fig. 9.—Boiler Pipe and Whistle.

require an intermittent action, but a continuous run down. So take firm hold of the *lower* pellet, and break it off. Being hard steel, it will readily snap. Hold the other part firmly, so as not to break both off. Now set the clock aside for a time. Then make a bearing to connect the catgut at right angles, for which purpose we require a pulley-wheel (such as are used by venetian blind makers, and sold in London about sixpence per dozen). This is fitted in the slot in the back of case by passing a piece of wire through the wheel, and soldering to the case. As this has to bear a considerable strain, the ends of the wire should be bent over, and let into the case before soldering. This will ensure the necessary strength.

We now require to make the match-holder and axle (Fig. 4), which consists of an upright piece of wire, $\frac{1}{8}$ in. thick by $4\frac{1}{8}$ in. long, to which, at a point 1 in. from bottom, is fitted another pulley-wheel, of the same kind just described. This is readily fastened by first drilling a hole on each side of the centre, passing a piece of bent wire through, as shown in Fig. 5, and soldering to the upright. Bore another small hole, and insert a screw, D. This will later on be connected to the catgut. At the upper end of Fig. 4 will be seen the match-holder, which is simply a piece of tin or zinc, 1 in. long by 1 in. wide, bent over a piece of $\frac{1}{8}$ in. wire, and pinched in under the wire, leaving a kind of tube when the wire is withdrawn. This is soldered to the upright, 1 in. from the top, and at right angles to the screw, D. A piece of tinned or brass wire is bent, as E, with an eye $\frac{5}{8}$ in. from the holder, F, leaving $1\frac{3}{4}$ in. extending in the opposite direction. This is soldered to the holder and to the upright, neat and strong. The next operation is to provide bearings for this work. The lower one will consist of the bottom of the case. For the upper one we must make an angle-piece (C, Fig. 2)—a piece of stout brass or zinc, $\frac{3}{4}$ in. wide, $7\frac{1}{4}$ in. long, bent to a right angle, 4 in. by 3 in., and soldered, the longer end to top of case, the shorter end to back of case, at a point $1\frac{1}{4}$ in. from the right-hand outside of case. Before soldering up, however, a hole to admit the upright should be punched in the shorter piece, at a point $1\frac{1}{4}$ in. from the bend. Having soldered this up, make a corresponding hole in the bottom of case, exactly under the other, so that the match-holder action-work will be vertical—that is, as shown in Fig. 4. If the measurements have been correctly made, you should have about $\frac{1}{8}$ in. to spare of the upright wire at each hole; and you can now secure this into its place, so that while it is free to move round, it cannot move up or down, by soldering at each end a bead of solder slightly larger than the holes.

We now require a small spirit lamp (Fig. 6), which is easily made of sheet zinc. The lamp is circular, with a square base, $1\frac{3}{8}$ in. high to shoulder, the part which forms the burner extending $\frac{1}{2}$ in. higher, having a diameter of $1\frac{1}{4}$ in. A "hank" of ordinary white darning cotton cut into three and placed inside the lamp forms a capital wick. The latter should not project above the lamp when in use, or it will hinder the action of the slide-cover. This cover is connected with an upright wire soldered to side of lamp (Fig. 6), and at a point level with top of lamp. A ledge is soldered to the wire. A hole is made in the extended side of cover, and is passed over the wire. A bead of solder on top serves to secure it, while leaving it free to move. Across the cover is soldered a semi-circular piece of tin, against which the wire at the opposite end of match strikes and knocks it away.

We have now to make the holder for the striking surface (Fig. 7), which is given full size, and is simply a piece of tin with edge and corner turned over at dotted lines. This is attached to a piece of crinoline steel spring, and soldered at its other end to the right-hand upright of case. It is best before soldering to pierce the steel, and insert a portion of an ordinary pin—the head part, and as much as is wanted of the stem. The steel must be softened at the ends to enable this to be done, which is readily effected by holding the ends in a lamp-flame till slightly red, and letting it cool of itself. It can then be punched with the point of a centre-punch or bradawl. The spring, when in position, should be curved inwards, so that the eye of match-holder just clears it. Thus, when the projecting match is in the holder, it will strike with some force. I prefer to use safety matches—the large size, Bryant and May's—and in the striker I place a piece of their friction surfaces, which are sold at most Italian warehouses at twopence per packet. Each sheet cuts into three, and each of the three is used four times—that is, I turn a different corner to the path of the match each time. Thus, a twopenny packet will last about nine months, daily use. I keep the box of matches in the case at the left-hand of lamp, and solder a strip of tin upright, which serves as a holder for the match-box, and keeps the lamp in position. The latter is best made with a square bottom, and to fit easily into the space left of the floor of the case. The lamp, of course, should be under the hole in top of case which was provided for the boiler (Fig. 9), which is 4 in. deep by 3 in. wide. The top extends $\frac{3}{8}$ in. beyond, all round. A piece of compo. pipe, $\frac{1}{4}$ in. bore, is soldered into top, near edge, and reaches to nearly the bottom; or, what is better, cut the pipe on the "skew," so that the water can run easily. A brass screw-cap is used for the filling hole, and a brass whistle (H) is made in an elbow form. Take a piece of brass tube, $\frac{1}{4}$ in. bore, $2\frac{3}{4}$ in. long. Saw off $\frac{3}{4}$ in., so as to make a mitre, and on the longer piece, $\frac{3}{4}$ in. from mitre, file an angular cut (Fig. 8). Stop up the longer end with solder, and insert in the shorter end a piece of cane or hard wood, the exact size of the tube, having previously filed the top flat, about $\frac{1}{16}$ in., slightly more at the mitred end. Just try it, and if you like the tone, secure the wood in its place by drilling a very small hole, and pass a pin in and solder to tube. Now solder the shorter end to top of the boiler, having previously made a hole at the spot. Next take a piece of suitable ordinary "bell-check" steel spring. Fasten the loop end to a piece of wire, and having passed the wire through the base of clock case, at the right-hand corner extreme point, solder underneath, and bend the other end of spring wire over the screw, D, in Fig. 5, so that when at rest it pulls over the striker a little beyond its proper position of being over centre of lamp.

There remains now only to fix clock movement into position, and connect the catgut (through the opening of clock case back) with the striking work at the point D. This is easily done by giving the gut a turn over D, and tying it to the wire over wheel. The gut should be so fixed that it brings back the striker to its position to centre of lamp. It will be necessary, of course, to pass the gut round the wheel, and the point D should be in the position of right angles to the striker. Now, if you wind up the alarm, you will see the action of the brass stop, before referred to. Take it off and adjust it when you have wound the gut up far enough to bring the striker to the right-hand side of case, so as to be easily manipulated in fixing match, and taking out the same. Stop its further turning by putting the stop so that it can turn no further. Replace the pin. Try the work a few times, seeing that the alarm escapement frees itself readily, and the work runs down with a sudden run. This being found all right, paint the whole (except clock) with black japan, and, when dry, slide into position the clock face. Fix on the hands and pendulum, and all is ready for use. I find about half a pint of spirit is used in a fortnight. As spirit easily evaporates, the cover must be put back as soon as lamp is blown out. Do not put the match in holder until wound up. I use a small china tea-pot, set under the pipe of boiler, for tea, and a jug for coffee. The apparatus makes these or cocoa admirably, from the fact that the water is actually boiling over when it comes into contact with either.

## AN ASBESTOS LEAD JOINT RUNNER.

BY J. C. KING.

A PLUMBER is supposed to carry his kit of tools and melting pot, with some solder, with him, and do a job at joint soldering in a place which is sometimes almost out of sight and often difficult to reach.

Sometimes contriving an appliance to hold up the lead or solder to a joint to be wiped or scraped in the best manner, the awkward position admits of little chance of a clean job. The inventions of plumbers' tools have been slow, and differ but little year after year; yet the want of such handy appliances is felt alike by masters and workmen, especially at the away-from-shop jobs.

The invention now illustrated is by William Vanderman, 21, Church Street, Willimantic, Connecticut, U.S., and is intended to serve for running a joint for soil, water, or gas pipes, or bell pipes of any kind where a joint is poured with molten lead. It consists of a specially woven asbestos rope, with a safety chain down the centre, with tapering ferrules on the ends of the rope, fastened to the chain with a hook on one end and a coil spring and extension of chain on the other end, to draw round the pipe to get the rope in position below the joint that has to be run.

Asbestos Lead Joint Runner.

To operate it, make the lap on the top of the pipe with the tapered end under; draw tight, pass chain under pipe to opposite side, let the pull draw on the spring to take up any slack of the rope, and attach the hook to chain to keep all tight.

Be sure there is no space or opening except the space intended into which the lead is to be poured. If there is, press the joint runner up close against hub or lap. The

molten lead or solder will not injure the asbestos or bring any of it off to spoil a nice joint.

The usual plan of a putty or clay gasket, in some jobs stuck up like a swallow's nest, while the solder is baled with a spoon from a ladle and poured at a joint, is quite uncertain in results, as the clay or putty may be too hard or too soft, or get into the joint and spoil it.

No doubt this invention will lead to asbestos belting with chain inside for some forms of joint gaskets.

## OUR GUIDE TO GOOD THINGS.

**** Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

### 61.—Messrs. Marris and Cooke's "Victor" Child's Carriage.

In Vol. II., page 142, of WORK, I had the pleasure of calling the attention of readers to

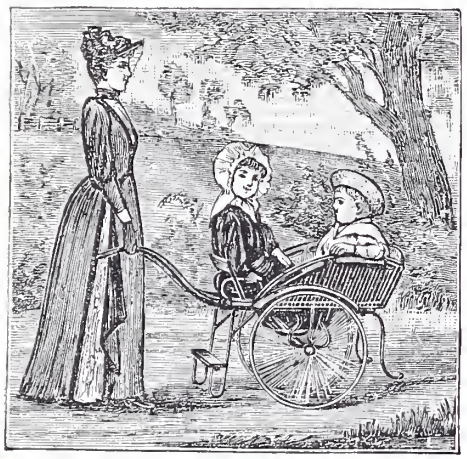

**Fig. 1.—Messrs. Marris and Cooke's "Victor" Child's Carriage.**

the original form of the "Victor" Child's Carriage, invented, patented, and manufactured by Messrs. Marris and Cooke, of Grimsby, who are also the proprietors of the Victor Bicycle advertised in these pages. The "Victor" Carriage in its earliest form was an excellent vehicle for children, and especially for children who were strong and active enough to take their turn in the shafts and draw one another; but its new development certainly has the merit of being more attractive in appearance, and is, in every way, more suitable and convenient as a child's carriage when mistress or maid is the motive power. This will be apparent to all who will take the trouble to compare the illustration given above with that in page 142 of Vol. II., over which it presents many decided advantages. Among these are the position and form of the shafts or handles, which are so contrived and affixed as to render it unnecessary for the tallest person to stoop when pushing it; and the carriage itself, which is level, or nearly so, when in transit, remains so when the shafts are relinquished by the driver, as when these are let down it rests on the irons which carry the front step; and, further, the irons attached to the back of the car prevent its being tilted up beyond a certain extent, and at the same time are not so long as to touch the ground when the carriage is being pushed along in a level position. The front seat is reversible, so that the child who occupies it may sit facing or with its back to the occupant of the back seat, the feet of both children being in the well of the car when the children are face to face. By means of two pieces of wood laid between the seats a bed is formed, on which an invalid child can recline with ease. It is well painted and nicely finished; it moves easily and without jolting on its springs; and its bicycle wheels are furnished with rubber tires, which render them absolutely noiseless, and

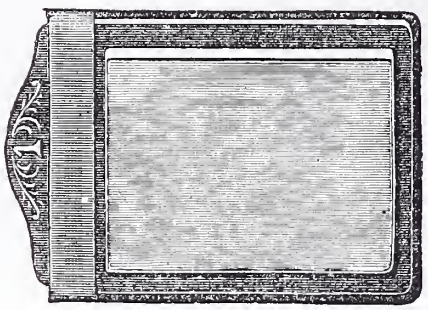

**Fig. 2.—Tylar's Single Metal Dark Slide: Shut.**

protected by broad mud-guards, which serve the double purpose of protecting the children from any mud that may be thrown up by the wheels, and also of preventing them from attempting to touch the wheels, which children are sometimes apt to do. The price, carriage paid to any part of the United Kingdom, is £2 5s. It compares favourably with, if it does not excel, any child's carriage of its kind, or any perambulator now in the market.

### 62.—Tylar's New Patent Single Metal Dark Slide.

This new invention of Mr. William Tylar, 57, High Street, Aston, Birmingham, and one of his most recent additions to his already large stock of photographic novelties, is specially designed for use in detective cameras, although there is nothing about it to prevent its use, generally speaking, in cameras so constructed as to admit of the use of dark slides. Its construction will be recognised from the accompanying illustrations, of which Fig. 2 represents it with the slide in or closed, and Fig. 3 with the slide withdrawn or open. To the back of the flat frame, which is shown in front, is attached a sheet of metal, moulded in the form of a shallow tray, and the slide or shutter works closely but not too tightly and stiffly in the groove, formed by the back of the frame and the upper surface of the margin of the back, rendering the dark slide absolutely light-proof. Below the groove, two projecting pieces of metal are attached to the sides of the

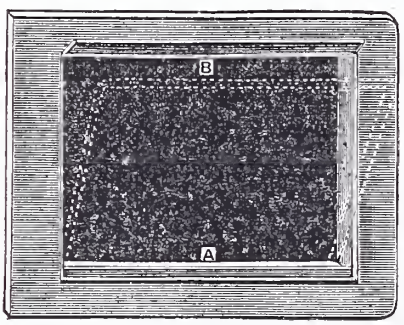

**Fig. 3.—Tylar's Single Metal Dark Slide: Open.**

rim of the so-called tray. That at A is fixed, and one side of the plate, which is dropped in from the front, as shown by the dotted lines in Fig. 3, is pushed under it. The slip at B lifts up, as shown in the illustration, and is closed down on the plate, thus holding it in position. Every slide and every shutter are interchangeable. They are supplied as ¼ plate slides, at 15s. per dozen: or at 20s. in a sling canvas case with focussing screen register. Mr. Tylar sends with this cheap and excellent machine-made slide a little finder for detective cameras, in the form of a small triangular box. The shorter sides are at right angles to one another, and are furnished, one with a lens and the other with a small ground glass plate, 1 in. by ⅞ in., on which the image of the object to be photographed is shown. It is fitted with perforated lugs for purposes of attachment, and is supplied at 2s. THE EDITOR.

## SUGGESTIONS FOR WORKERS AND HINTS TO INVENTORS.

AMMONIA GAS ENGINES.—For very many years inventors have been endeavouring to devise a form of boiler in which ammonia can be profitably used in place of water. As, to give a pressure of 100 lbs. to the square inch, the latter must be heated to a temperature of 300°, while ammonia will give the same pressure when raised to 60° only, the enormous saving of fuel secured by using the latter is obvious. Unfortunately, however, ammonia is not so cheap as water by a long way, and its use can only be commercially successful if the gas evolved can be recondensed into a liquid so as to be again subjected to expansion by the application of heat. According to a New York journal, an American inventor has succeeded in fitting a condensing apparatus to his boiler, which goes a long way towards solving the problem. No one, however, has successfully tackled it on this side of the Atlantic as yet, and ingenious minds may find the hint useful. It is quite possible that the ammonia engine may, under certain circumstances, form the intermediate link between the steam engine and the electric motor.

MECHANICAL SHOE BLACKING.—Considering the millions of boots and shoes which require blacking daily, it seems strange that no one has thought of producing a handy little apparatus which would save time and trouble when performing this operation. Electricity has already been pressed into service to drive mechanical blackers in certain shops at Paris and some of the larger American cities, but they are fitted up rather to attract customers than to effect any economy. Moreover, the average British housekeeper has not, as yet, laid on electricity into his house for motor purposes. The field is still open for the production of a cheap, handy, and effective substitute for the brushes. It need hardly be said that the shine produced by rapidly revolving polishers is, as evidenced by the electrical polishers to which we refer, much superior to that appearing on the boot blacked in the ordinary way.

WELDING COPPER.—Amateurs often ask for some easily applied process for welding copper—*i.e.*, dispensing with the use of spelter, and the consequent yellow marks along the seam when the operation is completed. To such the following description of an effective process may be useful, but it must be premised that great care in its performance is necessary, and that a first attempt is liable to be unsuccessful. The edges to be welded should be brought to a dull red heat, and most carefully cleaned from scale or ash. Then take 124 parts boracic acid and 358 parts phosphate of soda; mix them thoroughly, and apply to the seam. Increase the heat until the metal becomes cherry-red, and then, using a *wooden* (not an iron) hammer, weld the edges together. Non-success sometimes arises from either the edges being imperfectly cleaned or from want of judgment as to the colour of the metal before commencing to weld. The result, however, when successful, is very neat.

GAS METER.—The recent case, in which a gentleman, dissatisfied with the record of his company's gas meter, fitted an extra one at his own expense, which indicated greater consumption than the official meter, shows the need of a *really* accurate meter. Inventive ingenuity should be directed towards devising an apparatus for providing uniform pressure of gas before it enters the indexing chambers. Gas companies usually have their meters tested under the same, or nearly the same, conditions, whereas, as every gas-burning resident knows, the pressure from the mains often differs widely on different days of the week.

## A Corner for Those who Want to Talk It.

*** In consequence of the great pressure upon the "Shop" columns of* Work, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—Letter from a Correspondent.

**Testing the Accuracy of Framework.**—J. C. K. (*London, N.W.*) writes:—"In Work, p. 326, I read a simple way of testing the accuracy of framework by two diagonal measurements, having seen a similar statement, almost, in Work, May 2, 1891, thus: 'And a final check on its accuracy taken by measuring it across diagonally from corner to corner, when, if both diagonals are equal, the board will be square.' Though I do not think anyone will be misled into testing for squareness by this erroneous plan, I venture to send a sketch of a trapezoid, which has, at Fig. 1, a base line and two lines nearly at right angles to it, forming ends or sides, each line exactly $4\frac{7}{12}$ in. long and 5 in. on the top or opposite parallel line or side of an assumed

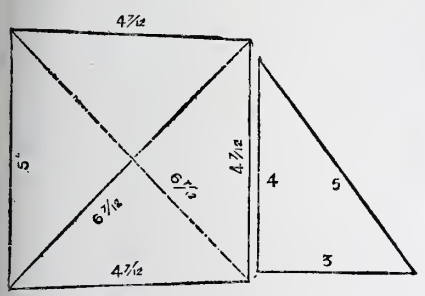

Fig. 1 Fig 2

Framework-testing Diagrams.

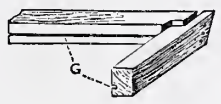
square. We will measure the two diagonal lines shown by the lines of dots. They are each exactly the same, $6\frac{7}{12}$ in., yet the sides are not square with the base line or top line, nor are the sides parallel with each other. There are several ways of ensuring accuracy of squareness to a frame, etc., by compasses or rule measure. One of the simplest and, perhaps, oldest known—practised by the slave workmen of Egypt and Greece thirty centuries ago—is to subtend a line from a base to a perpendicular, the base being as 4, the perpendicular 3, and the hypothenuse 5. This 3, 4, 5 is an immutable law of geometric proportion, and proves two sides are right-angled or square."

### II.—Questions Answered by Editor and Staff.

**Model Dynamo.**—A Novice.—Mr. Bottone, Wallington, Surrey, makes a small model Siemens dynamo capable of lighting a 5 c.-p. lamp, and sells this machine for 15s.; castings in the rough for the same machine at 5s. the set. He will also supply you with a 10 c.-p. machine for 30s., or a 20 c.-p. machine for 50s. If you care to get the castings and make the machine yourself, you will find full instructions in "Model Electric Lights," published in Work, No. 92, Vol. II., on December 20th, 1890. If you choose a 20 c.-p. machine, run it on two 10 c.-p. lamps, instead of one of 20 c.-p. You can get suitable lamps from the vendor of the machine. The machine will work best on a firm foundation, but, as it will have to be run at 3,000 revolutions per minute, it must not be in a shaky position. The lamp may be close up to the machine if so desired, but must not be subjected to severe jolting. If you will read carefully the series of articles on "Model Electric Lights," which appeared in Vol. II., I think you will obtain all necessary information on dynamos, lamps, etc. etc.—G. E. B.

**Carbon Plates.**—M. C. (*Lewisham, S.E.*).—Carbon plates may be made of powdered gas carbon (not powdered charcoal) mixed with treacle to a paste, compressed in iron moulds of the required shape, and baked in the moulds. Powdered charcoal mixed with resin or shellac will not do for the purpose even when baked in a mould, as the mixture would be too friable, and the plate be a bad conductor of electricity. As carbon plates are sold at a low price, it will not repay an amateur to make them himself. Gas carbon may be cut into plates by means of an old saw or a strip of sheet iron improvised as a saw, together with wet silver sand. An unlimited supply of elbow grease will also be required. As you can get carbon plates at a cheap rate from Messrs. Peppercorn, Broadway, Deptford; or from Bonney & Co., 19, Avenue Road, Lewisham, it will not pay you to cut them from gas carbon.—G. E. B.

**Bromide Enlargements.**—Water.—Procure your lengths of pitch pine wood 3 in. wide by 1 in. thick. Cut out a groove about ¼ in. deep, and 1 in. from one edge along the side of each piece—which, of course, must be of the proper length for the tray in question. The corners, instead of being mitred together, are best rebated. The preliminaries having been made ready, the grooves and corners should be well smeared with a mixture of ground red and white lead, made just thin enough, and no more, to work with gold size. Three sides of the frame being securely screwed together, a piece of stout glass is pushed into the groove, close up, leaving ¼ in. projecting to fit into the end piece, which is now carefully pressed on, and well screwed at the corners. Now we have a dish with wooden



sides and glass bottom, but not *sufficiently* watertight. Let this dry well in a warm current of air for a week, when we can set to work to render it absolutely waterproof with equal parts of pitch and paraffin wax *carefully* melted together, and well stirred during the operation. Having warmed the dish by the fire, and got it thoroughly dry, with a ladle pour some of the melted composition into all the corners, inside and out. If it happens to set too soon, get a hot spatula and rub it in. You will now have a thoroughly watertight dish, which had better be filled with water, and let stand one night, to dissolve anything prejudicial that may have been in the cement. Once more dry, and give the woodwork a coat inside and out with shellac dissolved in methylated spirits. When this is dry—which will be the case in a few hours—the dish is ready for use. Of course, small dishes may be made of lighter wood on the same principle. Pitch and paraffin wax is one of the best cements for this sort of dish. The accompanying diagram will show how the woodwork is put together.—D.

**School of Electrical Engineering.**—N. R. (*Carlisle*).—I think you are perfectly justified in making strict inquiries respecting the character of the school and its principal before parting with any money. Although I am not personally known to any of the gentlemen named in your letter, I should not doubt their good faith in recommending the school, as it cannot be of any personal interest to them to risk their characters by a false representation. The letters A.I.E.E. attached to a name represent that the owner is an Associate of the Institution of Electrical Engineers. On searching the members' list of this institution, I find the name among its associates. The school has been established several years, and is, I believe, doing good work.—G. E. B.

**Incandescent Gas Burners.**—C. B. V. (*Aldershot*).—If the pressure of the gas supply is weak, I think the light will not be improved by using incandescent gas burners, as my experience with these leads me to observe that they are useless when the pressure of gas is low. If the pressure of gas is fairly high, these burners give out a glowing, white, hot light, and they also give out considerable heat—more than an ordinary burner. They are useful where a room is to be lighted and heated with gas. I do not know the particular make mentioned in your letter, so cannot give the address of the maker. As you get such a bad light from gas, I recommend you to get some good oil lamps, as these give the next best light to good gas, and cost less than electric lights. If you have the power at hand to drive a small dynamo, then, as you have a good workshop and tools, why not make one, and lay down a small installation of electric light? You will find full instructions in "Model Electric Lights," published in Vol. II. of Work.—G. E. B.

**Motive Power for Dynamo.**—J. M. (*Hebburn-on-Tyne*).—Your idea, when worked out, should result in perpetual motion, if this were possible. If you could make a small dynamo to work a motor with part of its current, and then gear the motor to the dynamo, and thus work the same dynamo with its own current-driven motor, you would completely solve the question of perpetual motion. This equals the idea of a young friend of mine, who thought he could arrange a system of syphons to carry the tail water of a mill back into the mill-pond, and thus prevent waste of water. Suppose it takes, say, 100 units of power to drive a small dynamo 3,000 revolutions per minute. Part of this power will be used up in overcoming friction in the machine and belting, and part in heating the wires of the motor, still more in friction of the motor; so that we shall only get, at the best, about 70 units from the motor. As some of this will be lost in the friction of gearing with the dynamo, we shall only get about 50 units of power from the motor, or only half enough to drive the dynamo, even when the motor is supplied with *all* the current from the dynamo.—G. E. B.

**Water Engine.**—Water.—It is not possible to advise you without an inspection of the engine. Cannot you get a friend in your locality to look at it? Any working fitter could do so.—J.

**Bench Maker.**—J. O. H. (*Wandsworth*).—There is a cabinet bench maker in Old Street, St. Luke's, E.C., nearly opposite Pitfield Street, Hollis by name; but carpenters usually make their own benches.—B. A. B.

**Galvanometer.**—Galvanometer.—Take a needle, a little thicker than that fixed in the base-board, and fix at the eye end a piece of wood to form a handle, and using this in the same manner as a bradawl, work it carefully through between the coils of wire in the centre of bobbin, and when through, work it round to enlarge the hole, and slip it over the needle in the base-board. By using a little care, you can get the needle through without injuring the covering of the wire. Or you may fix a pin in the centre of bobbin before the wire is put on, and draw it out after the wire is wound on. You must be careful to fix the needle in the base perfectly square from the board, and at the proper height for the magnetic needle to be in the centre of the opening; also not to damage the point of the needle, and to make the conical hole in the brass very accurate, so that the needle will swing easily, as this will be more likely to impair the working of the instrument than if you should slightly abrade the covering of the wire.—M.

**Frosting Ornaments.**—A Would-be Decorator.—I have never heard of powdered mica, so cannot tell you where to buy it. As regards your difficulty, it is evident the acid has not sufficiently acted upon the mica; either it was not strong enough, or you did not boil it sufficiently long. Get the strongest acid and the thinnest sheets of mica, and try again, when you ought to succeed.—W. E. D., Jr.

**Chemical Apparatus.**—J. S. (*Little Horton*).—Put water into your flask, and suspend in it, by means of a string, a muslin bag containing your herbs. As the water distils over, it carries with it a little of the essential oil of the herb. Should any oil collect on the surface of the water, it can be drawn off. The oil which is dissolved in the water can be separated from it by saturating the liquid with common salt, when the oil rises to the surface.—F. B. C.

**Oil Painting on Silk.**—P. MacN. (*Shettlesworth*).—A preparation for this is sold by artists' colourmen, but the purpose will be served by dissolving a little isinglass in water, and sizing the silk with it. Take care to size it slightly *beyond* the future outline of the painting, or the oil will run.—S. W.

**Porcelain Studies.**—S. T. (*Amsterdam*).—As these are required *wholesale*, you are advised to apply direct to Messrs. Raphael Tuck & Sons, London.—S. W.

**Watch-Case Engraving.**—J. H. (*Ballina*).—Send your watch case to Messrs. Grimshaw & Co., 35, Goswell Road, Clerkenwell, or Haswell & Sons, 49 and 50, Spencer Street, Clerkenwell, either of whom will re-engrave or engine-turn it and repolish as new, the price being about 2s. or 3s., depending on being a double case or an open face.—A. B. C.

**White Pitch.**—W. W. (*Bristol*).—This is also called Burgundy pitch, and is obtained from pine resin or white resin. It is of a pale yellow colour, and is sold by most chemists; the price is, I believe, about 2d. per oz. If you cannot procure any, if you write me through our Editor, I can get you some. There are also Venice turpentine and Canada balsam, both of which are light-coloured gums, and which harden by exposure.—M.

**Answers in Work.**—J. W. H. (*Nottingham*).—While writing, why did you not repeat your queries?

**Medical Battery.**—Reader.—It is not enough to simply describe the battery as a "constant current battery." There are many types of constant current batteries. I must know the name of your battery before I can tell you how to re-charge it. If you cannot give me the name of the maker or of the type of battery, I must trouble you for a complete description of it; then I can give directions for re-charging the cells, and say nearly the probable cost. The address of Messrs. J. & A. Churchill is 11, New Burlington Street, London, W.—G. E. B.

**Low Voltage Incandescent Lamps.**—Lamps.—The lowest voltage lamps are those of one candle-power, having a voltage of from 3 to 8 volts. Then there are lamps of two and a half candle-power, having voltages ranging from 5 to 25 volts. If you will apply to Mr. Bottone, Wallington, Surrey, and tell him exactly what you wish to do, he will advise you as to the best lamps for the purpose of floral decoration, and supply you with all things necessary for the installation.—G. E. B.

**Electric Belt.**—J. A. R. (*Wandsworth*).—The current obtainable from such a belt, as proposed by you, would be very feeble. The pockets containing the zinc discs should be all on the inside, and the pockets containing the copper discs all on the outside, of the belt, opposite to each other, with only a thin partition of flannel between. The outside discs of copper should be connected to the inside discs of zinc in each alternate pair, and thus make a battery of the whole. I do not see how a belt of alternate pieces of copper and of German silver wire, connected "on the thermopile principle," can do any good. The heat from your body would not be sufficient to make such an arrangement a good thermopile. But, whatever arrangement you may determine upon, the effect upon your body will be in accordance with your faith in its efficacy. The curative action of all these electric belts is much increased by faith.—G. E. B.

**Copal Varnish for Floorcloth.**—H. F. (*Gateshead-on-Tyne*).—If the copal or oak varnish is evenly applied by a brush, and allowed a reasonable time to harden before being used, it would undoubtedly do much to preserve your floorcloth from wearing out so soon. At any rate, it will freshen up the appearance, though it will be well to bear in mind that the wear is on both sides, the underside being usually protected by a coat of paint. As you say your varnish dries in the open air, but not indoors, would it not be better to remove the whole outdoors some fine day and do it there, first taking the precaution of well washing it with some soda water (a handful of washing soda to a gallon of water), and wiping quite dry? If the varnish has thickened by keeping, it will be necessary to thin it down a little with turpentine—not naphtha, as you suggest—and the addition of a little japanners' gold size will assist its drying properties.—LIFEBOAT.

**Pin-hole Photography.**—JOHNNY GILPIN.—The number of WORK in which the article appeared is No. 17. The plates used, and the development of the same, are precisely the same as for other photographic work. The only difference between pin-hole photography and that with ordinary lenses is that the pin-hole image is *never* absolutely sharp, but that the focus is always the right one, no matter at what distance the objects may be from the camera. The exposure is always very prolonged, so much so, that pin-hole photography is useless for ordinary work or dark subjects. The exposure is regulated by the square of the distance between the pin-hole and plate, and also the size of the picture by the distance between them. The size of the plate is quite immaterial, as, at a proper distance, *any* sized plate can be covered; but with very large sizes the loss of light is so considerable as to render photography impracticable.—D.

**Oak Stain.**—READER OF "WORK."—You would have done well had you told us for what particular purpose you required the stain. Do you wish to stain common white wood in imitation of oak? or do you wish to make light oak darker? Had you given us these particulars, your question could have been answered more fully and to the point; as it is, we can only answer in a general way. To stain common white wood in imitation of oak by the aid of spirit stains and varnishes is a rather ticklish job for an amateur; to stain the colour of oak is a comparatively easy matter. It can be done by giving one or more coats of asphaltum dissolved in turpentine or coal tar naphtha (¼ lb. crushed asphaltum to a pint of turps); or you may thin down brunswick black with turps. The former is the most cleanly to use. Both must be used alone, not mixed with varnish; and both can be varnished over with spirit varnish, after first allowing a reasonable time to elapse for them to dry. If it is light oak that needs to be made darker, the asphaltum stain is a useful one, though the correct and most cleanly way is by means of fumigation, particulars of which you will find in "Shop," under the heading of "Stain" (p. 219, June 20th, 1891). If, on the other hand, it is cheap furniture you wish to do, you might do worse than read a reply given in "Shop" on "Graining Cheap Furniture," that appeared in the issue of June 6th, 1891 (p. 187). You will find there some useful hints. You say you have tried umber and spirits, but it does not suit. This would have been all right had you given the work a coat of patent size or varnish first, that had been stained by the addition of a little yellow ochre or lemon chrome—so forming a yellow ground to work on. The umber stain should be mixed with three parts spirits, one part polishor varnish (not all spirits). If, when this is applied, and while still wet, a grainer's steel comb is drawn over it, a passable imitation of oak will be the result. Finish by giving a coat of clear varnish. I append a couple of recipes for brown oak stains: (1) Mix together 2 oz. of pearlash and 2 oz. American potash in a quart of warm water, and apply to the parts to be stained. (2) 2 oz. vandyke brown, ½ pint liquid ammonia, ½ oz. bichromate of potash. A tinge of red in the polish or varnish will improve these. If stained varnishes are used, care should be taken to carefully strain through fine muslin before using; and you will be more likely to gain an even surface if the work has been previously sized over.—LIFEBOAT.

**Looking-Glass.**—F. L. (*West Cowes*).—Any glass merchant or furniture dealer will supply you with the above at about 3s. per foot super. But if you want such a quantity as would repay you for the cost of carriage, I should advise you to write to one or two large firms in London or Manchester for special quotations.—E. D.

**Lathe Making.**—LATHE-STRUCK.—It is well to be enthusiastic about the charming and useful art of turning, if your enthusiasm leads to patient and persevering work rather than trying to jump to the top of the tree at a single bound! Pray don't attempt to *make* a lathe till you know how to *use* one. Can't you get some workman friend to let you use his in the evening, when he has done work? You say you have no lathe, nor access to any; yet you write from a town where there must be a great many, and if you can't pay for the use of a lathe, you can, perhaps, earn the loan of one by working for its owner. Offer to go errands, etc., for some turner, for instance. If he will let you try your hand, make yourself useful to him, help him in any way you can *in his work*, and let him see you want to learn; and when you have worked at the lathe some two or three years, and can turn wood and metal, use files, chisels, tags, and dies; make and use drills; forge slide-rest tools; and, in short, when you have mastered the *a*, *b*, *c*, then you may think of making a lathe. Don't let your enthusiasm tempt you to try to do impossibilities, but rein it in, and make it keep you to the practicable.—F. A. M.

**Paint.**—H. E. R. (*York*).—If you had stated in what way the wall was damp, and from what cause, I might have been able to have given you a remedy far preferable to paint. Write to the Damp-proof Paint Co., Cannon Street, London, for particulars of their paint, and if you are not successful with it, let me know more about the damp, and no doubt we can get over the difficulty.—E. D.

**Waterproof Glue.**—F. B. (*Aldershot*).—If your two letters to the Glue Company had no fuller address than the one you sent us—which is quoted above—it is no wonder that you have received no answer to your communications. When you write a letter, you should add your full name and address.

**Printers' Roller Composition.**—POTASH.—A "compo." which is an improvement on the old glue and treacle, is said to be made of glycerine and gum; but instead of making, POTASH will be far wiser to buy his compo. ready mixed, as he can do from any printers' broker at from 1s. to 1s. 6d. per lb. The Durable Patent Roller Composition is sold only by the company so named (57, Shoe Lane, London, E.C.) and their agents.—S. W.

**Fixing Carbon.**—NO NAME.—Le Page's glue, or any bicycle cement, will fasten a piece of carbon to ferrotype or wood. These cements are very useful for all such purposes.—W. D.

**Safe Locks.**—J. A. (*Walsall*).—I cannot do better, in answer to your query, than quote Mr. Chatwood, the eminent safe maker. "In an ordinary lever lock, the bolt has fixed upon it, at right angles, a projection called the main stump, and each of the levers has a passage or gating, which, in a well-made lock, should be no wider than is absolutely necessary for the stumps to pass through. In unlocking the lock, all these levers have to be raised, each exactly to its right position, before the bolt can be withdrawn. If anyone of them should be raised too high, or not raised sufficiently, the stump is blocked, and therefore the bolt cannot be withdrawn. At the first glance it would appear impossible to pick such a lock, if the number of levers be considerable. The key has a number of steps, each of which—except the bottom one—lifts one of the levers. The bottom step then engages with the bolt, and draws it back. To pick such a lock, pressure is applied to the bolt, so as to cause the main stump to press against the face of the levers; then, by raising each lever in turn, the position of the gating is easily ascertained by the difference between the friction on the lever when pressed by the main stump and when in position and no longer pressed by the main stump. In a lock with many levers, special appliances are necessary for these purposes. The apparatus used in picking lever locks consists of a tubular key having one step upon it, and a solid key fitting inside it, and also having one step upon it, having an ordinary key bow with a lever arm carrying a small weight. These can be operated quite independently of one another. The step in the solid key engages with the talon of the bolt, and the weight on the lever arm attached to it causes the stump to be forced with suitable pressure against the faces of the levers. By means of the step on the tubular key, the levers are raised in turn to feel for their gatings, and as each is found, extra pressure necessary to retain them in position is provided by moving the weight along the lever arm. When all the levers have been thus arranged, the bolt is withdrawn." Lever locks with patented improvements, such as are now manufactured by Messrs. Hobbs, Hart & Co., and Messrs. Chubb, are practically unpickable.—T. W.

**Distemper Lines.**—J. B. (*Manchester*).—Lines of colour may be run with lining-fitch and straight-edge upon paper, distemper, or such-like absorbent surface either as "size colour" or "turps colour." For the former, mix *best* venetian red powder with water to a stiff paste, then thin for use with strong jelly size. This must be kept warm in using, as you may surmise. For turps colour, use japan gold size to make the dry pigment into "batter" consistency, then thin for use with turps. Both of these should work well and stand sizing. The simplest plan for blocking marble is a red or black pencil drawn round a wooden frame of block size.—F. P.

**Smooth Surface for Decoration.**—G. S. R. (*Tewkesbury*).—When a wall is badly plastered, no subsequent rubbing or smoothing will remedy the mischief. The best that can be done is either to prepare it in distemper, or to line it. After removing the old paper, and washing down the walls thoroughly to remove the old paste, etc., make some distemper (see Index, Vol. II.), but with *double* the quantity of *size*. Give the wall a good coat of this, used just warm, which will fill a lot of cracks, etc. Stop holes, etc., with plaster, and when all is dry, rub down with "coarse 2" glass-paper. It can now be treated with alabastine direct, or—a much better job—give it first a thin coat of oily paint. *Lining* the wall—viz., covering it with a stout white lining-paper—requires a paper-hanger's skill; and the wall must be also well prepared. The first is the easiest and dirtiest, and the latter the quickest and dearest, plan.—F. P.

**Japanese Leather Papers.**—F. R. E. (*Darlington*).—For Japanese leather goods, etc., *wholesale* and in large quantities, write Messrs. Rottman, Strome & Co., St. Mary Axe, London, who are makers, having factories at Yokohama, Japan. Maw & Co., Farringdon Road, City, E.C., are also large importers of all oriental goods. For odd yards and remnants, write Liberty & Co., Regent Street, W.—F. P.

**Gilding on Varnish.**—F. R. E. (*Darlington*).—For this class of gilding oil gold size is used. The surface of varnish scarcely ever being free from sufficient "tackiness" to hold gold leaf, it is first necessary to coat the work all over with albumen of one egg blown into half a pint of luke warm water. Twist it into a froth with the brush, and brush on the froth. Use the gold size very barely. When gilded (see recent article), wash off the egg size with hot water and soft sponge, which removes also all superfluous gold leaf.—F. P.

**Battery for Electric Light.**—F. G. (*Paddington, W.*).—Get four glass pickle jars or marmalade jars 7 in. by 4 in. The mouths of these should be from 2½ in. to 3 in. in diameter. Get for each bottle two carbon plates 7 in. by 2 in. by ¼ in., and one zinc plate 7 in. by 2 in. by ¼ in. Also get a binding screw clamp to fit each zinc plate, and a similar clamp with jaws 1 in. deep and 1½ in. apart, to clamp the carbon and zinc plates together in each jar. Amalgamate the zinc plates with mercury. Put the zinc clamps on the tops of the zinc plates, ½ in. at one side of the centre. Cut two strips from a cigar-box cover 3 in. by ⅝ in. for each zinc plate, place them along the top of each zinc plate on each side, place a carbon plate on each side of these, and clamp the whole together. The strips of wood will keep the carbon plates from touching the zinc plate, and the deep-jawed clamps will connect the two carbons. If you do not care to go to the expense of brass clamps, place a strip of sheet copper between the top of the zinc and the wood, and two strips between the carbon plates and the wood on each side to form connections. Separate the zincs and carbons at the bottom by two similar pieces of wood, and bind the whole together with indiarubber bands. This is a cheap makeshift. Battery plates thus put together can be easily taken apart to be cleaned. Charge each cell with a solution of chromic acid and sulphuric acid in water, 3 oz. of each to each pint of water, and allow the solution to cool before using. You should get 8-volt lamps to use with a battery of four such cells. Place the battery in a box in a cupboard or in the cellar, and lead No. 18 copper wires from the battery to the lamp-holders on the piano. Each lamp must be covered with a conical shade to screen the eyes from the glare of the light, and throw this down on the music-book. A switch should be provided to throw the lamps in or out of action at pleasure.—G. E. B.

**Faulty Induction Coil.**—NEMO.—Although four medium size Leclanché cells placed in series do not furnish a battery strong enough to work an induction coil 9 in. by 5 in., the current from such a battery will magnetise the core, and cause the hammer to vibrate, if the coil has been properly made, and the connections are all right. If you can get a current from this battery "through the machine" without "any magnetic effect whatever on the core," then there must be a serious leakage across the primary, such as connection between the first turn of the first layer and the last turn of the last layer, or the both ends in contact with the core, foot of break spring, or similar good conductor. If I could see it, I could tell you in a few minutes where the fault lies. Without seeing it, I can only suggest the above as being the most likely fault. If the coil is properly made, it should take the current from six bichromate or chromic acid cells.—G. E. B.

**Electro-Magnetic Apparatus.**—F. H. (*Drayton Park*).—To work the apparatus described by you, it will be necessary to have a horseshoe magnet with cores 3 in. by ½ in. fitted with bobbins 1½ in. in diameter, wound to the full with No. 22 silk-covered copper wire. The weight to be lifted must be attached to an armature of soft iron, ½ in. by ½ in., and long enough to span the poles of the magnet. The current should be furnished by three medium size Leclanché cells in series. Connect the cells to the clock and to the electro-magnet with No. 18 wire; then you need not fear any serious decrease in power whether the machine is placed twenty or forty yards from the clock. A stud must be placed on the clock face, and a spring contact fitted to the hour hand to sweep over the stud each hour and keep in contact with it for five seconds. Used thus, if properly fitted up, the battery would probably retain its power and keep in working order for several months, perhaps a year.—G. E. B.

**Measuring Instrument.**—POLYGON.—The instrument about which you inquire is a sector, by the aid of which all questions in proportion may be solved; lines may be divided either equally or unequally into any number of parts that may be desired; the angular functions, viz., chords, sines, tangents, etc., may be set off or measured to any radius whatever; plans and drawings may be reduced or enlarged in any required proportions, and, in short, every operation in geometrical drawing may be performed by the aid of this instrument and the compasses only. I suppose yours is the ordinary six-inch sector, which, when opened, forms a rule of twelve inches; and this circumstance is taken advantage of by filling up the space not occupied by the sectoral lines with such lines as it is the most important to lay down upon a greater length than the six-inch plain scale will admit. Among these the most usual are (1) the lines of logarithmic numbers, sines, and tangents;

(2) a scale of twelve inches, in which each inch is divided into ten equal parts; and (3) a foot divided into ten equal primary divisions, each of which is sub-divided into ten equal parts, so that the whole is divided into one hundred equal parts. This last is called the decimal scale, and is placed on the edge of the instrument. The "sectoral lines" proceed in pairs from the centre, one line of each pair on either leg, and are, upon one face of the instrument, a pair of scales of equal parts, called the "line of lines," and marked L; a pair of lines of chords, marked C; a pair of lines of secants, marked S; and a pair of lines of polygons, marked POL. Upon the other face the sectoral lines are: a pair of lines of sines, marked S; a pair of lines of tangents up to 45°, marked T; and a second line of tangents to a lesser radius, extending from 45° to 75°. Each pair of sectoral lines, except the lines of polygons, should be so adjusted as to make equal angles at the centre, so that the distance from the centre to the corresponding divisions of any pairs of lines, and the transverse distance between these divisions, may always form similar triangles. On many instruments, however, the pairs of lines of secants and of tangents from 45° to 75° make angles at the centre equal to one another, but unequal to the angle made by all other pairs of lines. The divisions of each sectoral line are contained within three parallel lines, *the innermost* being the line on which the points of the compass are to be placed, because this is the only line of the three which goes to the centre, and is, therefore, the sectoral line. The line of polygons is chiefly used for the ready division of the circumference of a circle into any number of equal parts from 4 to 12—that is, as a ready means to inscribe regular polygons of any given number of sides from 4 to 12 within a given circle. To do which, set off the radius of the given circle (which is always equal to the side of an inscribed hexagon) as the transverse distance of 6 and 6 upon the line of polygons. Then the transverse distance of 4 and 4 will be the side of a square; the transverse distance between 5 and 5 the side of a pentagon; between 7 and 7, the side of a heptagon; and so on. If it be required to form a polygon upon a given straight line, set off the extent of the given line as a transverse distance between the points upon the line of polygons answering to the number of sides of which the polygon is to consist; as for a pentagon between 5 and 5; or for an octagon between 8 and 8; then the transverse distance between 6 and 6 will be the radius of a circle whose circumference would be divided by the given line into the number of sides required. All regular polygons, whose number of sides will exactly divide 360 (the number of degrees into which all circles are supposed to be divided) without a remainder, may likewise be set off upon the circumference of the circle by the *line of chords*. Thus, take the radius of the circle between the compasses, and open the sector till that extent becomes the transverse distance between 60 and 60 upon the line of chords; then, having divided 360 by the required number of sides, the transverse distance between the numbers of the quotient will be the side of the polygon required. Thus, for an octagon, take the distance between 45 $\left(\frac{360}{8}\right)$ and 45; and for a polygon of 36 sides take the distance between 10 and 10.—F. B. C.

**Varnish for Walking Sticks.** — C. BROS. (*Leeds*).—These, when done in large quantities, are generally finished by drying in a hot room or drying stove. Suitable varnishes are sold by most varnish makers, amongst whom, in your neighbourhood, you might write to or call upon Mr. H. O. Milnes, Leeds Road Varnish Works, Bradford, stating your requirements; he will, I think, be able to suit you. Also with a black varnish suitable for dipping your iron wire in. If, however, you have no drying stove, or large quantity of sticks to do, what are known as spirit varnishes are most suitable. Foremost among these is that known as brown hard spirit varnish, made as follows:—Gum sandarach, 4 ozs.; seed lac, 2 ozs.; gum elemi, 1 oz.; methylated spirits, 1½ pints; when dissolved, add Venice turpentine, 2 ozs. Another:—Rectified naphtha, 1½ pints; gum sandarach, 2 ozs.; best amber resin, 2 ozs.; gum benzoin, 4 ozs. Both must be carefully strained before using, then applied with a camel's-hair brush. If required harder, this can be done by adding one-third part of French polish, made by dissolving 6 or 8 oz. of best orange shellac in 1 pint of rectified naphtha.—LIFEBOAT.

**Cleaning Old Gilt Frames.**—A. E. S. (*Wootton Bassett*).—The only way, save re-gilding, of improving the appearance of old gilt frames is to wash off the dirt and fly marks contained in the coat of size which covers all gold framework. This may be done by using a small sponge barely moistened with hot spirits of wine or oil of turpentine; *do not wipe* afterwards, but leave to dry. This process requires great care.—F. B.

**Alloy.**—ALLOY.—This querist asks to be informed of a metal nearest in strength to iron, which will not rust, and which can be melted on an ordinary fire. I think the metal or alloy which complies nearest with these conditions is brass. This may be melted on a close range fire under favourable conditions, and though greatly below iron in strength, yet it comes nearest to it to comply with the other two conditions — viz., non-rusting and fusibility.—R. A.

**Pewterers' Flux.**—A. E. (*Langton*).—The flux generally used by pewterers for soldering pewter counters, pots, etc., is Gallipoli oil. It is an inferior kind of olive oil, of a greenish tint. I have not tried it, but should think ordinary flask olive oil would do as well. As regards the composition of Baker's fluid, I believe it is simply distilled and diluted chloride of zinc.—R. A.

**Melting Brass.**—NO NAME.—Figs. 1 to 4 illustrate the standard type of brass-melting furnace. Fig. 1 is a vertical section, through one of the furnaces and the chimney. Fig. 2 is, on the right-hand side, a section through the right-hand furnace (× × in Fig. 3, and Z Z in Fig. 1); and, on the left-hand side, a view in front of the left-hand furnace, seen from the ash-pit (Y Y in Fig. 3). Fig. 3 is a general plan; Fig. 4 a view of the cover. In these figures, A, A, are the melting holes or furnaces, measuring from 12 in. to 18 in. square, according to the amount of metal that requires to be melted. A 14 in. or 15 in. hole will take a pot with a melting capacity of 50 lbs. or 60 lbs. The depth of the furnaces will range from 2 ft. to 2 ft. 6 in. It is essential to give ample depth, in order that the crucible shall be entirely enclosed in the fuel. The reason why furnaces are built in twos or threes, is to get sufficient melting capacity for heavy casts; or even where that is not the case, to be able to use one furnace while the other may be undergoing repairs. Still, if you are an amateur, and intend only to melt brass for your own use, a single furnace will suffice. Underneath the furnace is the ash-pit (B) and the opening (B') through which the ashes are raked into the front area (C). In Figs. 1 and 2, the line D D represents the level of the stone or brick floor, into which the furnaces are built. The ash-

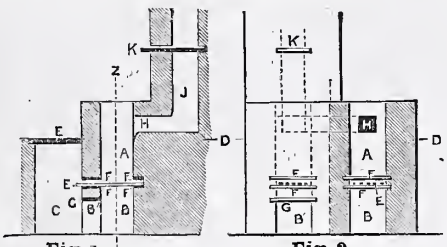


Fig. 1

Fig. 2

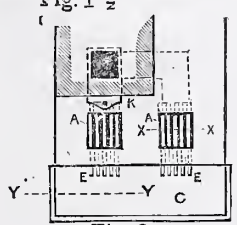

Fig. 3

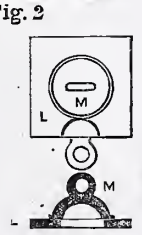

Fig. 4

Brass-melting Furnace.

pit (C), therefore, lies entirely beneath the floor level, and is covered over with a cast-iron grating (E). The object of this arrangement is to allow the attendant standing on the grating to be well over the furnaces, and so be able to exercise all his strength in lifting the pots of molten metal out of the furnaces. To clear the ashes out from underneath, it is necessary to remove the plate (E) and get down into the pit (C). E, E, in the figures are the fire-bars, upon which the fire is built; they are simply bars of wrought iron about 1 in. square, laid loosely across the bottom of the furnace. It is necessary to make them easily removable, so that the attendant, getting down into the ash-pit, C, may draw them out endwise, and let the cinders drop into the ash-pit, B. Replacing the bars, the fire can be rebuilt. In order that the constant removal and replacing of the bars shall not break away the brickwork, plates of iron (F, F) are built into the brickwork immediately above and below the bars. A similar plate (G) is built in to carry the brickwork over the opening B'. Both furnaces lead, by the openings H, into a common chimney (J); and the height of this chimney should not be less than from 12 ft. to 15 ft. A short chimney will not create sufficient draught to melt the metal quickly and properly, and artificial blast is not used for brass furnaces. The draught is regulated by means of the damper (K), placed in the chimney, and all the air necessary for combustion passes down through the perforated cast-iron plate (E). Fig. 4 shows a cover used for the mouths of the furnaces (A). L is a square cast-iron plate, having an eye cast in for sliding it on and off the furnace mouths. This plate is left in position during melting, but a light cast-iron top (M) is removed from time to time, for the purpose of watching the progress of the melting, and to throw in fresh fuel, if necessary. The furnace is built of fire-bricks, built with fire-clay joints, the clay being mixed with water to about the consistence of thick cream. Either gas coke or furnace coke can be used for melting brass, but the latter is more satisfactory, because of its heat-giving power. After the fire has been built, it is allowed to burn up, and then the crucible, with its charge of metal, is set about midway in the furnace, and covered over with fresh coke; the cover (L) and tile (M) are then put on, and the melting proceeds for an hour or more. You can purchase crucibles of the Morgan Crucible Company, Battersea; they will cost a trifle over one penny per pound of capacity. Now, in reference to the last part of your query, I am afraid I must refer you for the present to treatises written on the subject. The subject of moulding, to include that of the brass foundry, will be treated of in WORK by-and-by, and if so it will possess more practical value than any book I can recommend you. There is a book by Graham, price 2s., published by Crosby Lockwood & Co.; and there is another by Larkin, price 10s. 6d., which, I believe, is published by Spon. There is also Spretson's work, which contains a chapter on the brass foundry, one on fine-art work, and one on bell founding.—J.

**Re-tinning Rusty Spots.**—R. H. (*Notting Hill*).—In answer to your first query, I must say that I have seen a good many churns repaired, and also repaired many myself; but I never knew anyone "take on" the job of re-tinning the rusty patches—that is, unless there was a hole there, and a piece of tin had to be put on it. In this case, of course, the usual method of scraping or filing must be adopted to keep it clean, and then use spirits of salts and a soldering iron and solder to "tin" it preparatory to soldering on the piece. This is the usual, and, in fact, the only, way to get over it. If, as you say, you cannot get on with spirits of salts or resin (resin is no use for rusty tin), there must be something wrong, either with your materials or your method of procedure. (2) How to keep tools from turning rusty in a few hours after cleaning. You are quite right in supposing that this is caused mainly by the fumes of the spirits—this is one of the ills that tools are heir to in a tinman's shop. I will, however, offer a few suggestions that will help you to minimise the evil. In the first place, I would ask, Why do you want your tools bright? There are only a few tools that it is absolutely necessary to keep polished, such as the anvil, a few heads, and a few hammers. The anvil you should make a tin cover for, and grease the face of the anvil; for the hammer and head you can have wash-leather bags or caps to tie on over the faces, and keep them in a drawer when not in use, and clean them once a week whether they need it or not. The ordinary tools that lie about in constant use it is almost impossible to keep clean without constant looking after; but I find that, after they have got to a certain degree of tarnish, if they are rubbed occasionally with an oily rag, and then well rubbed dry, that they will scarcely be affected. Of course, faces of hammers and of tools will need to be rubbed up now and again. In conclusion, never keep any unkilled spirits of salts in the workshop, and cover your spirit jar when not in use, and I think you will go a great way to get over your little difficulty.—R. A.

**Patent Lock.**—A. M. (*Willenhall*).—If the patent for the lock still exists, you certainly must not make any imitation of it. Your best plan will be to consult a respectable patent agent, or approach the maker of the lock, and see if he will buy your improvement.—T. W.

**Relief Scraps on Screen.**—J. W. (*Morley*).—I know of nothing better than a stiff glue paste, such as that used for hanging Japanese "leather," and other heavy embossed papers. First dissolve the glue by boiling, and to prevent its burning to the bottom of the saucepan, wrap it in rag and tie it to the lid; then stir in the flour and boil. The paste should have time to soak into thick paper or card before fixing.—S. W.

**Prescription.**—SHEF.—We do not undertake to answer in WORK any questions appertaining to medical matters.

**Lime.**—E. F. B. (*No Address*).—You may mix the lime with coarse sand, fine gravel, coke breeze, crushed spar, or granite. The material should be screened through a mesh of the required size, and also screened a second time through a smaller mesh to remove the fine dust. You may put two parts to one of stone lime, and if chalk lime, rather less, unless the lime is very strong. You must not exceed this, or it will not set hard. You might try on a small quantity first. If you had said for what purpose, or how you mean to use it, I might have been able to give you more definite information. If you want it to set quickly, you could mix a little Portland cement or plaster of Paris with the lime. If this is not exactly what you require, if you write again, giving more particulars, I shall be glad to give you any further information.—M.

**Polish for Bookcase.**—H. A. W. (*Blyth*).—All dirt, grease, and furniture paste must be first removed by careful washing with soda and water and powdered pumice-stone or Bath brick (common washing soda the size of a walnut to a pint of warm water). It can then be French polished, if you like, but I cannot advise you to make your maiden efforts at polishing on anything with carvings and mouldings, etc., such as your clock case would be likely to have. Far better practice on some flat surfaces first, reading carefully the articles on French polishing appearing in the present volume of WORK. For the present, a decidedly fresher and more satisfactory appearance will be given by the application of one or two coats of brown hard spirit varnish, such as can be bought at any respectable oil and colour merchant's, to be applied carefully with a camel's-hair brush.—LIFEBOAT.

**Phonograph Cylinders.**—J. P. A. (*Walthamstow*).—I do not think it would be worth your while to try to make the above from your waste product. The demand at present does not seem to be very large. I could not undertake the trouble of inspecting one.—W. D.

III.—QUESTIONS SUBMITTED TO CORRESPONDENTS.

**Ink for Poster.**—C. B. (*Highbury*) writes:—"I shall be very much obliged to M. D. C. (*Liverpool*) if he will tell me how to mix a good red ink or paint for poster-writing. The stink of the benzine and oil paint recommended by SMILING SMUDGER is horrible. It also runs a little. Gum water is not of much use."

**Crimson Dye.**—G. B. (*London, W.*) writes:—"I should be much obliged for the ingredients for a good crimson dye, which would be economical and fast—for cloth."

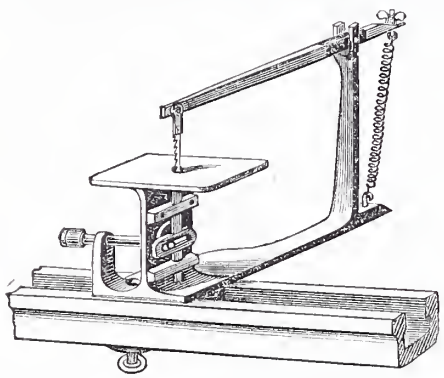
**Nets.**—C. C. (*Dartmouth*) asks:—"Could some correspondent kindly give in 'Shop' instructions, with drawings, as to how to make a trawl net for a 10 ft. beam? I should also be glad for notes concerning other nets."

**Upholstery.**—QUEEN'S ISLAND writes:—"Will any reader tell me how to cut the cloth to cover a couch so that it will be free of wrinkles, as those I have as yet covered do not look very well?"

**Cotton Band Machine.**—E. W. (*Halifax*) writes:—"Will any reader kindly inform me of the best and cheapest method of making a *small cotton band machine* to make lengths, say, from 1½ yd. to 2 yds. long?"

IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

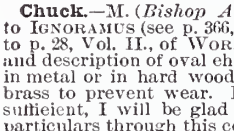
**Mandrel for Lathes.**—J. A. M. (*Stamford Hill, N.*) writes, in reply to J. T. (*Walworth*) (see page 159, Vol. II.):—"For jobbing engineering work I can recommend A. W. Salter, 15, Brunswick Street,



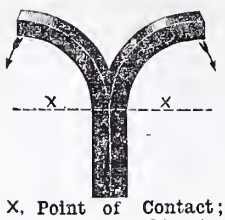
Hackney Road. He has done a good deal for me, and has forge, steam power, and almost every needful appliance at hand. Above is a drawing of a fret-saw attachment for my lathe which he has just made, and which will, I think, prove a serviceable tool."

**Chuck.**—M. (*Bishop Auckland*) writes, in reply to IGNORAMUS (see p. 366, No. 127):—"If you refer to p. 28, Vol. II., of WORK, you will find sketches and description of oval chuck, which you can make in metal or in hard wood, facing the V slides with brass to prevent wear. If the information is not sufficient, I will be glad to give you any further particulars through this column, if you write again. I can get you the castings, if you send me your address."

**Galvanometer.**—F. S. (*Normanton*) writes, in reply to GALVANIC (see page 206, No. 117):—"I will tell how I made a cheap and simple galvanometer. If, like me, GALVANIC is hard up, it will be just the thing he wants, as it cost me but a trifle, and any amateur could make it. First, I made a box like a linesman's detector; that is, two halves hinged together, 5 in. by 3¾ in. by 2½ in. Before putting on the front, I cut a hole 3 in. in diameter, and into this fitted a glass, which I got off an old bicycle lamp, and thus had glass and rim complete. I made the dial by taking a thin piece of wood, just large enough to fit inside the front half, and pasted on a sheet of white paper. Then on the side on which the paper was pasted I fixed my needle, which I made out of an old coil spring, and made it 1½ in. long for the support. I took a piece of brass shaped as in diagram, A being needle and axle, B piece of thin brass clamped between dial and angle brass, and C being angle brass. The needle simply rested on pivots, the bottom being slightly heavier to keep in the centre of the dial. I must not forget to say that the needle was magnetised. At the back of the dial I fixed a bobbin of wire (six layers No. 24 s.c.) lengthways across the dial, and connected the ends to terminals at the top of the box. On sending a current round the coils of wire, the needle was deflected to either side, according to which way the current was sent. To give the dial a finished appearance, I drew two half circles round the top of the needle which represented the graduations. If GALVANIC liked, he could fix a horseshoe electro-magnet to the back of the box, with the poles pressing against the back of the dial, but this would not be so good as a coil, as he would have to find which way to send the current to repel the needle; but perhaps some other reader could describe a better galvanometer, as this would be of no use for a professional electrician."



**Joining Vulcanite, Steel Etching, Rubber Stamps, etc.**—H. B. (*Sheffield*) writes:—"I have gone through the Indexes of Vols. I. and II. of WORK, but cannot find the description of a method to fasten together two pieces of polished vulcanite. I shall be greatly obliged if any of your correspondents can inform me what composition to use without heat or need for repolishing to securely fasten together two flat surfaces, say, ⅜ in. square, at bottom of strips 4 in. long by ½ in. wide, to resist a strain of 1 lb., as shown on enclosed sketch, and also to withstand the action of water. Some years ago a patented process was shown in Sheffield to etch upon steel direct from a rubber stamp in conjunction with certain acid salts, and was called 'E. Menstacta's New Direct Etching Process'; it is now, I believe, impossible to procure in this country the particular mixture of salts used. Could you inform me, through the medium of WORK, what ingredients to use which, in a plastic state, would contain sufficient power to light etch into steel direct from a rubber stamp a word moulded from 'nonpareil condensed type,' which, as you will probably be aware, does not carry a great body of ink in printing?"



X, Point of Contact; + Direction of Strain.

**Lace Frame.**—C. E. M. (*Birkenhead*) writes, in reply to MART (see page 14, No. 105): "Here is a description of a simple macramé lace frame, which I have found quite as convenient as any of more elaborate construction. Smooth a piece of pine, 28 in. by 8 in. by ⅜ in. thick; at each end of this screw on a piece 8 in. by 1½ in. high, and ⅜ in. thick. The screws must be put in from the back, three to each piece. On the outside of each of these insert a row of about twelve round-headed screws, ½ in. apart. Those on the right-hand end should be put in at an angle of 45°, points down. (Fig. 1.) The reason for this

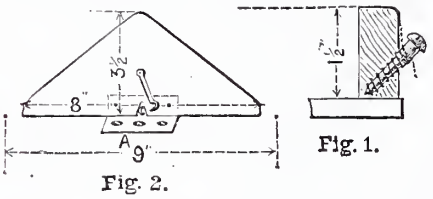


Fig. 2.

Fig. 1.

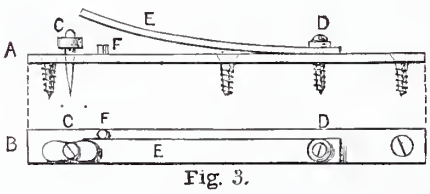

Fig. 3.

Lace Frame. Fig. 1.—Section of Right-hand End; Dotted Line, Foundation Cord. Fig. 2.—Flap—A, Hinge and Notch in Wood to allow for Eye. Fig. 3.—Brass Attachment—A, Side View (open); B, Top View (closed); C, C, Button; D, D, Pivot Screw and Washer; E, E, Spring; F, F, Small Brass Stud, to prevent Displacement of Spring.

is that, when a foundation cord is stretched across the board, it only requires one turn round the screw to secure it tight. The secret of making good macramé lace lies in having the foundation cords strained as tight as possible. A couple of flaps are hinged on to the back of the board, about 4 in. from each end. When the board is in use it rests on these, which are held in position by hook and eye. (Fig. 2.) At the left-hand side of my board I have screwed a brass attachment, for gripping the lace when a long piece is being worked. It consists of a brass plate 8 in. by ⅝ in. by 1/16 in., to which is attached a piece of spring-brass, one end turning on a pivot, while the other is placed under a brass button when in use, and kept in place by a small stud. (Fig. 3.)"

V.—BRIEF ACKNOWLEDGMENTS.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—D. S. (*Glasgow*); W. M. (*Dundee*); A. G. (*Dublin*); LISFARREN; F. R. (*Salford*); T. W. (*Bolton*); J. B. (*Stoke Newington*); E. J. (*Yeovil*); DENIS; JACK PLANE; J. O. H. (*Nottingham Road*); R. J. H. (*Penzance*); E. B. (*Dorsetshire*); W. P. (*Scarborough*); F. W. & SON (*Billingshurst*); YOUNG CHIPS; H. N. (*Ballycanew*); M. & C. (*Grimsby*); CHOPSTICK; W. D. (*Belfast*); E. H. (*Warrington*); S. B. # A WONDERFUL MEDICINE.

# BEECHAM'S PILLS

Are universally admitted to be worth a Guinea a Box for Bilious and Nervous Disorders, such as Wind and Pain in the Stomach, Sick Headache, Giddiness, Fulness and Swelling after Meals, Dizziness and Drowsiness, Cold Chills, Flushings of Heat, Loss of Appetite, Shortness of Breath, Costiveness, Scurvy and Blotches on the Skin, Disturbed Sleep, and all Nervous and Trembling Sensations, &c. &c. The first dose will give relief in twenty minutes. This is no fiction, for they have done it in countless cases. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

**Worth a Guinea a Box.**

FOR FEMALES THESE PILLS ARE

"A priceless boon, a treasure more than wealth; the banisher of pain, the key to health."

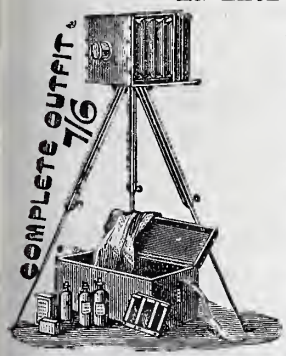
These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the nervous and debilitated is,

***BEECHAM'S PILLS have the Largest Sale of any Patent Medicine in the World.***

Prepared only by the Proprietor, T. BEECHAM, St. Helen's, Lancashire, in Boxes 9½d., 1s. 1½d., and 2s. 9d. each. Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*

## AMATEUR PHOTOGRAPHY.

*AN EXCELLENT OPPORTUNITY FOR BEGINNERS.*



In making their Cheap Photographic Sets for Boys, and Beginners whose means are limited, J. H. SKINNER & CO. have striven to reach the **maximum of efficiency, combined with the minimum of cost.** This they claim to have now attained by using the best machinery wherever practicable, and by selling them at a small profit they are able to place in the market their **Improved Eclipse Cameras and Outfits,** which for quality and price combined defy successful competition. Every set guaranteed perfect, and if found otherwise on receipt will be exchanged or money refunded on return of goods.

**THE IMPROVED ECLIPSE CAMERA SET, price 3s. 6d.,**

Consists of a full ¼-plate sliding bellows Camera (taking pictures up to 4¼ in. by 3¼ in.), made of solid mahogany, polished, fitted with a good double convex, brass-mounted lens, improved dark slide, light-proof; focussing-screen, improved focussing arrangement, packet of dry plates, developing and fixing solutions, and full instructions, enabling any amateur to take a good Photograph. Price **3s. 6d.;** or securely packed by Parcels Post, **4s.**

**7s. 6d. COMPLETE PHOTOGRAPHIC OUTFITS. 7s. 6d.**

Comprising ECLIPSE CAMERA SET, as above: also PHOTOGRAPHIC PRINTING APPARATUS, consisting of hardwood printing frame, with brass spring back, sensitised albuminised paper, gold toning solution, fixing solution, glass rods, cards for mounting, with complete instructions. Also hardwood folding tripod stand and focussing cloth. Price **7s. 6d.;** securely packed, post free, **8s. 6d.** If packed in portable wood case, with hinged lid and leather strap, as in Illustration, **9d.** extra. Every set is carefully examined before being sent out, and guaranteed to be in working order. N.B.—If Apparatus does not give satisfaction, and is returned uninjured within three days of receipt, we guarantee to refund purchase-money.

**THE STANLEY OUTFIT, price 10s. 6d.; by Parcels Post, 11s. 6d.**

This set is precisely the same as the 7s. 6d. Outfit, except that it includes a better Camera, with folding tailboard, a double dark slide, and is sent out packed in hardwood box, with hinged lid and leather strap, without extra charge.

**The Marvel, Norfolk, or Compacta ¼-plate Camera Sets,** price **£1 1s.** each; or by Parcels Post, **1s.** extra. These sets consist of a superior ¼-plate Camera, with hinged focussing screen, will take horizontal or vertical pictures, mahogany double dark slide, superior achromatic lens in sliding brass mount; also polished hardwood folding tripod.

For better sets, see our Photographic Catalogue, price **2d.,** post free.

***A Wholesale Dealer's Stock-in-Trade at about Half-Price.***

J. H. S. & CO. having purchased from the Trustee the Stock-in-Trade of Mr. J. Methersill, of 6, Southampton Row, and 60, Holloway Road, London, at a large reduction off cost price, are offering it at a little more than half ordinary prices. Send for List, post free on application.

**J. H. SKINNER & CO., Manufacturers, W Department, EAST DEREHAM.**

## FRETWORK FOR AMATEURS

OF BOTH SEXES AND ALL AGES

The most Fascinating and Profitable of all Home Pastimes

250 000 Fretwork Designs, 100,000 ft. Solid & 3-Ply Fretwood Veneers, etc., 1,000 gross Fretsaws, etc., always in Stock.

**To Beginners—A Complete Outfit, 2s. 6d., post free.** Comprising 12 in. Steel Frame, 24 Saw Blades, Awl, File, 3 Designs, with sufficient planed Fretwood, and full Instructions. 6 ft. assorted planed Fretwood, 2s. 6d.; 12 ft. ditto, 4s. 3d., post free. Book containing 12 sheets full-size Designs, 1s. Fretsaws 1s. 4d. per gross.

New Catalogues of Machines, Designs, Wood, Tools, etc., with 60 pages and 600 Illustrations, and full instructions for Fret-cutting, Polishing, and Varnishing, price 4d., post free. A Specimen 6d. Fretwork Design SENT GRATIS with each Catalogue; also a List of Designs, Outfits, Tool Chests, etc., at Greatly Reduced Prices to clear. N.B.—All orders MUST be accompanied by remittance. Apply—**J. H. SKINNER & CO.,** Manufacturers of Fretwork Materials, **W** Department, **East Dereham, Norfolk.**

*Kindly mention this paper when ordering.*

### A CABINET FOR OLD CHINA.

BY F. JERMAN.

INTRODUCTION — SIZES OF MATERIAL — WOOD — CONSTRUCTION—DOORS AND FITTINGS—PAINTING—CONCLUSION.

MOST of the readers of WORK, I daresay, have hobbies. Some go in for collecting stamps or birds' eggs, or in making collections of rare objects from the mineral and vegetable kingdoms. Perhaps a few are collectors of old china, and naturally want a cabinet in which they can show the fruit of their labours to the best advantage; and at the same time stow them away safe from the ravages of the domestic servant, who, under the pretence of "dusting," would gladly smash everything destructible in a house: the most valuable articles being, of course, the first to be destroyed. The article shown in the accompanying design may at first sight appear too complicated for the amateur carpenter to make, but on a close study of the drawings and reading the following directions these difficulties will vanish. The design is of a cabinet that I have just completed myself, and I think that any other amateur can "go and do likewise" if he has a well-stored chest of good tools. In execution it looks very well, although the small moulds around the panels are all stock patterns. This cabinet can be made into an excellent bookcase, being much preferable to a few open shelves, the glazed front effectually keeping out the dust; and the cupboard beneath would then be a good place to keep unbound magazines and journals.

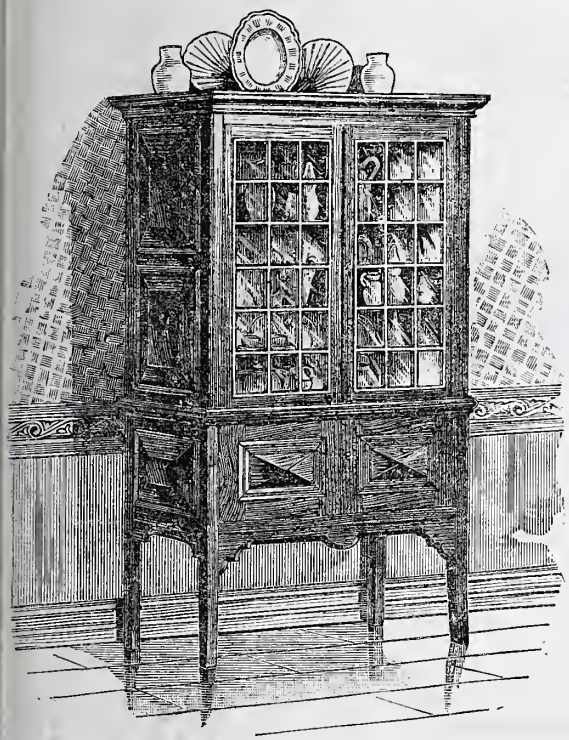

Fig. 1.—Perspective View of Cabinet for Old China.

The following are the measurements and lengths of wood required:—

1¾ in. square in four corner posts, 22 ft. run; 1¾ in. square stuff elsewhere, 22½ ft. run; ⅜ in. back, 11 ft. 8 in. super.; 1½ in. top, A, 4 ft. 3 in. super.; 1¼ in. shelf, B, 4 ft. 3 in. super.; 1¼ in. shelf at C, 3 ft. 6 in. super.; ¾ in. four shelves in cabinet, 13 ft. 4 in. super.; 1 in. mould round sides, 15 ft. 8 in. run; 2 in. bolection mould in front panels, 8 ft. 4 in. run. The glazed frames in front are formed of 1 in. by ⅞ in. stuff, with ½ in. bars. The

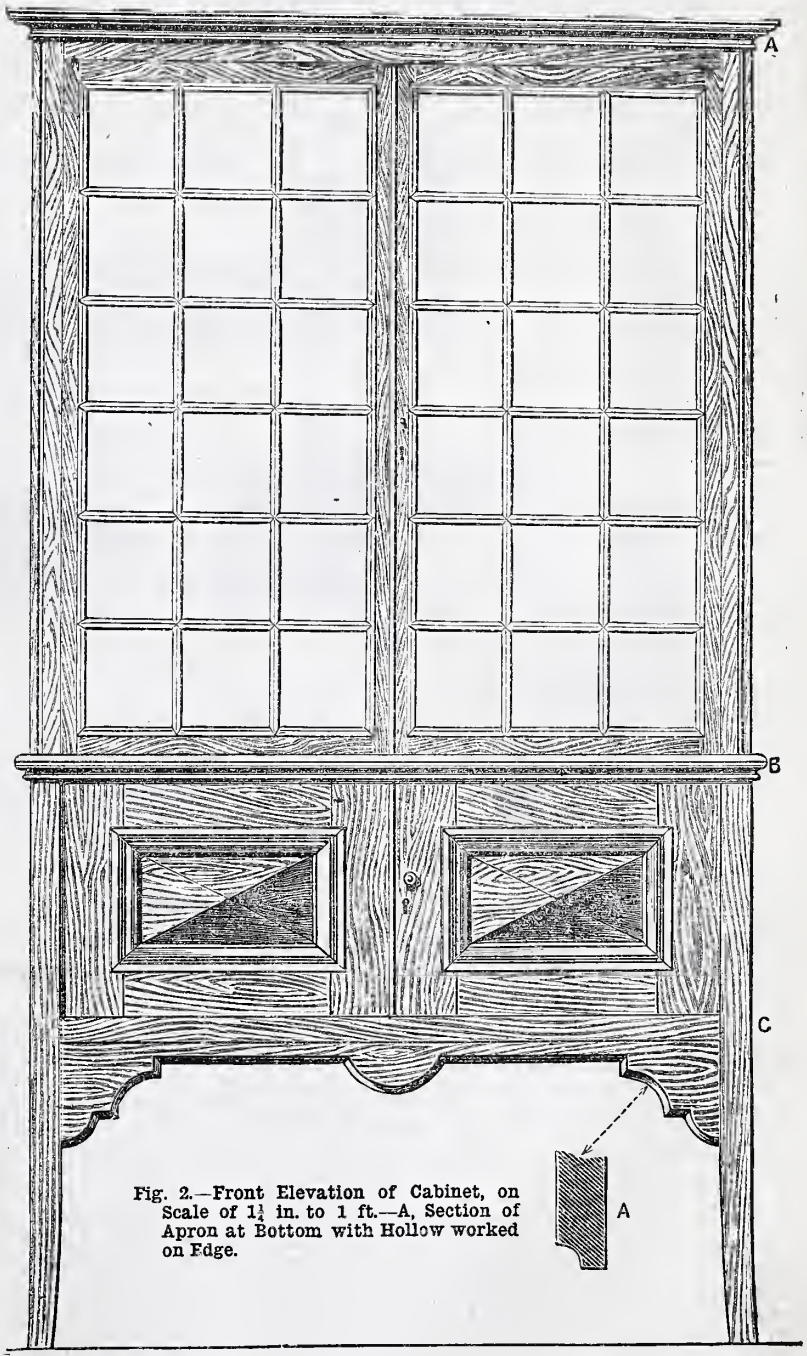

Fig. 2.—Front Elevation of Cabinet, on Scale of 1¼ in. to 1 ft.—A, Section of Apron at Bottom with Hollow worked on Edge.

frames to lower doors are 3 in. by $\frac{7}{8}$ in., with $\frac{5}{8}$ in. bevelled panels. The panels at the side are of 1 in. stuff, also bevelled. The size of the cabinet when finished is 5 ft. 6 in. high, 3 ft. broad, and 1 ft. 3 in. deep, outside measurements.

If an inexpensive cabinet is desired, the wood used may be red or yellow deal.

The angle uprights should be first cut out, the two in front to diminish at the bottom. Between A and B (Fig. 2) a bead is worked on the angles, and a groove is made for the side panels. The front uprights must be rebated $\frac{1}{4}$ in. for the glazed doors, and the two back uprights rebated $\frac{1}{2}$ in., as shown. The horizontal pieces grooved similarly for the panels must now be tenoned into these uprights, the panels being got ready and fitted into the grooves at the same time, similar to the manner in which a panel door is made. The moulds are then mitred properly and bradded on. The ornamental apron at the bottom is cut out of 11 in. by $\frac{1}{2}$ in. stuff, and tongued into the uprights, etc. A hollow is worked on the edge, as shown at A (Fig. 2). On each of the sides of the cabinet four strips of 2 in. by $\frac{3}{4}$ in. stuff are tenoned into the uprights to take the shelves. The shelf, B, is $1\frac{1}{4}$ in. thick, with 1 in. projection; a mould is worked on the outer edge, and the square holes for the front uprights are chiselled out carefully, and holes are cut also for the back ones. This method of keeping the shelf in one piece necessitates more care and time than if the mould is merely planted on; but, on the other hand, it adds to its good appearance, and makes a better job. This shelf and the top, A, are firmly secured to the horizontal pieces. The shelf, C, is $1\frac{1}{4}$ in. thick, rebated and screwed to the horizontal pieces all round, and cut out where the angle studs occur. The four intermediate shelves, three in the glazed front and one in the cupboard underneath, of $\frac{3}{4}$ in. stuff, are now screwed to the pieces mentioned above for the purpose. As an appearance of lightness and elegance is required in a cabinet of this description, the moulding at A is purposely made of very little height. It is worked on the top piece $1\frac{1}{2}$ in. thick, thus dispensing with the heavy cornice which is usually fixed on sideboards, wardrobes, etc. The back can now be placed in the rebates, care being taken to fix the pieces firmly together, with triangular strips nailed round to keep them in close.

Everything is now in position except the doors. The glazed doors are each 2 ft. 10 in. high and 1 ft. $4\frac{1}{2}$ in. in breadth, with frames and bars as before mentioned and rebated meeting styles. The glass is 21 oz. best sheet, care being taken to choose it without flaws and bubbles. Fit the panes with beads inside, bradded on instead of puttying. The doors are hung with small brass butts. A couple of small bolts are required in one leaf, and a small china handle and lock and key on the other. The frames of the two lower doors to cupboard are tenoned together, and a 2 in. mould run round panel. The hinges and fastenings are similar to those in the glazed front.

An excellent method of treating the cabinet is to paint it three coats, leaving the panels a sage green, the frames a blue green (called, I believe, "French" green), and the mouldings picked out in dark green and black, and afterwards varnishing the whole.

The sketch in Fig. 1 gives an idea of how the work will look when completed, and I think the above description will make everything clear. If there is anything that any reader may not understand, I shall be pleased to correspond with him through the columns of "Shop." I do not, however, think that any woodworker of average capacity and skill will find much that is difficult in the construction of the cabinet. The parts that will prove most troublesome are the glazed doors, but it is recommended that the style shown in Figs. 1 and 2 should be adhered to, as it is thoroughly in harmony with the other parts.

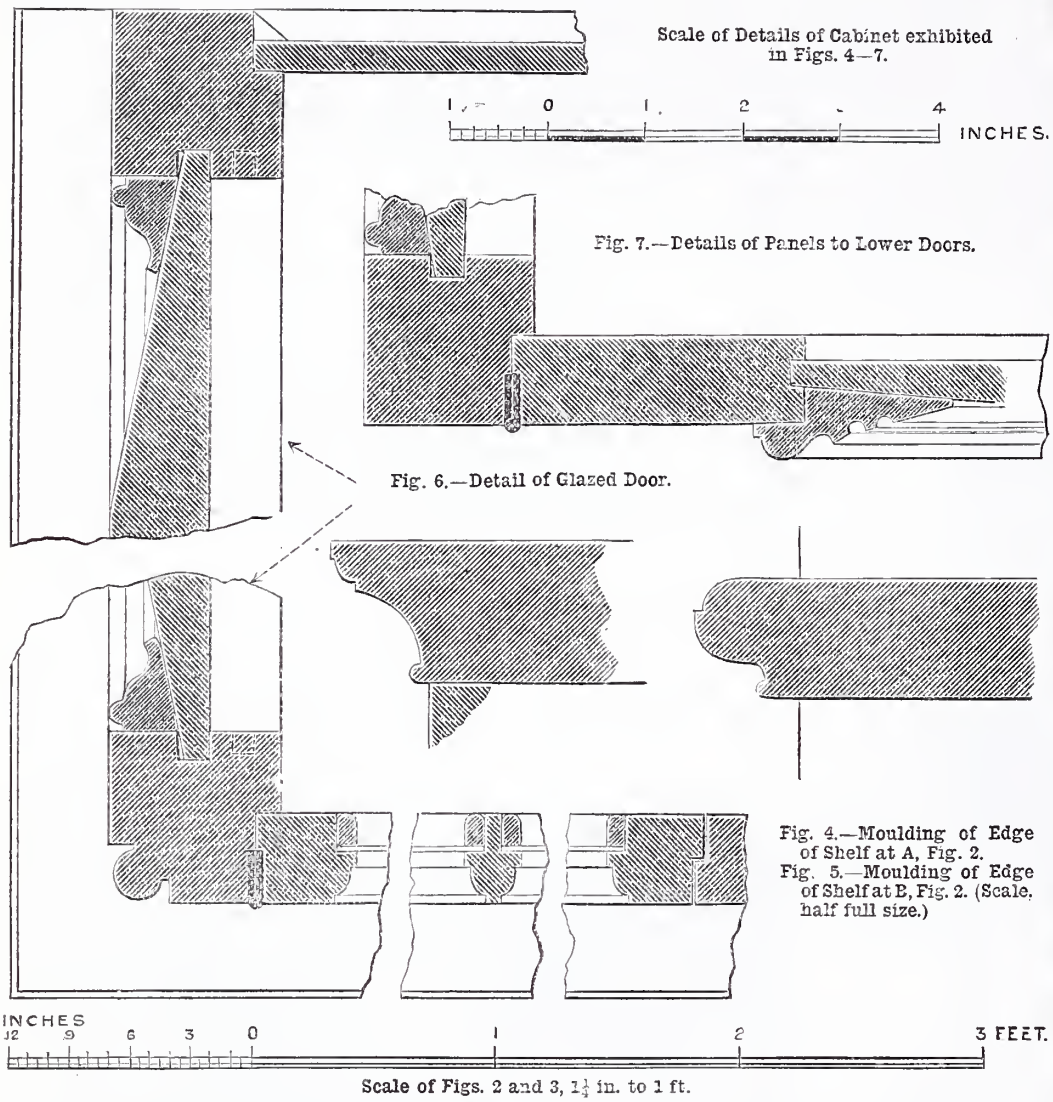

Fig. 7.—Details of Panels to Lower Doors.

Fig. 6.—Detail of Glazed Door.

Fig. 4.—Moulding of Edge of Shelf at A, Fig. 2.
Fig. 5.—Moulding of Edge of Shelf at B, Fig. 2. (Scale, half full size.)

Scale of Figs. 2 and 3, $1\frac{1}{4}$ in. to 1 ft.

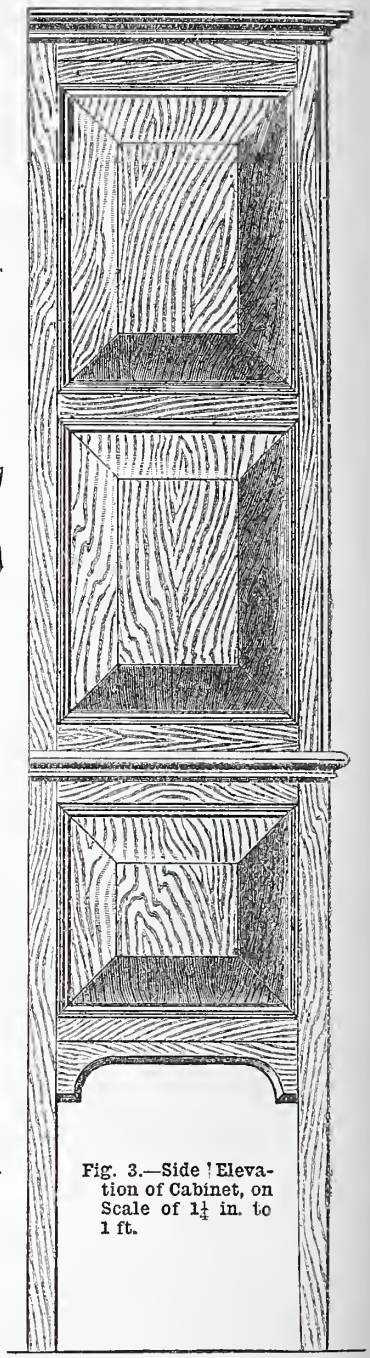

Fig. 3.—Side Elevation of Cabinet, on Scale of $1\frac{1}{4}$ in. to 1 ft.

## THE SAFETY BICYCLE: ITS PRACTICAL CONSTRUCTION, ETC.

BY A. S. P.

FRAME READY FOR THE FITTINGS—MAKING AND BENDING L-PIN—BRAKE-WORK—BRAKE LEVER—LAMP BRACKET—MUD-GUARDS—ADJUSTING PINS—DRIVING AXLE AND CHAIN WHEEL—CRANKS AND PEDALS—FOOT-RESTS AND STEP—SADDLE AND SPRING.

WE left our frame brazed up and finished ready for the various fittings, such as brake-work, mud-guard, L-pin, etc., and we have the frame with these parts in place in the annexed illustration (Fig. 29). The other figures accompanying this chapter are Fig. 30, L-pin; Fig. 31, A, B, brake lever; Fig. 32, A, B, brake spoon; Fig. 33, A, B, adjusting ring with lamp bracket; Fig. 34, brake-spoon hingeing-pin (full size); Fig. 35, adjustable brake-rod complete: A, the $\frac{3}{8}$ in. tube; B, the rod; C, the lower fork for attaching to spoon back; D, the upper fork for attaching to brake lever (Fig. 31); E, adjusting piece with set-screw (Fig. 38) fixed on upper end of tube, A; Fig. 36, ends of mud-guard stay-rods that fit on to axles (full size); Fig. 37, A, B, spring bracket for L-pin.

We will now proceed to the making and fitting of these parts, and first of all the L-pin (Fig. 30). It is made from a bit of round steel bar turned to $\frac{5}{8}$ in. exactly; it takes 13 in. of stuff to make. After being turned and smoothed ready for the final polishing, it is bent to a right angle, the two arms being equal lengths. The bending may be easily done as follows: heat up to a bright red in the centre; cool both ends in water, leaving $1\frac{1}{2}$ in. in the centre red; then grip in a vice and slip a piece of tube on the other end to act as a lever, and the bar will be easily bent to the required angle. Of course, the whole thing has to be done pretty smartly in order not to lose the heat. After bending, the L-pin has to be finished for nickel-plating by polishing on the emery-wheels, or, in the absence of wheels, with fine files, emery-cloth, and oil. In draw-filing with fine files it is an improvement to chalk the file. All cross file marks must be removed by draw-filing before the work is ready for emery-cloth.

Before finishing L-pin see that it moves freely in the vertical socket in the frame, and that the spring bracket (Fig. 37) also moves freely on it. The ends of the L-pin should be nicely rounded, and after the whole is polished with the finest emery-cloth it is ready for the plater.

We next take in hand the brake-work. The spoon (Fig. 32) is a stamping or casting; A is the upper side, B the side view. The end C is that which receives the hingeing-pin (Fig. 34). This part of the spoon is as long as fits in between the fork sides; it is bored right through for the pin $\frac{5}{16}$ in.; its face within the fork sides is $\frac{1}{2}$ in. clear of the wheel rubber. A hole is bored through each of the fork sides to receive the pin, that on the one side being the full size of the pin, that on the other somewhat less, and tapped for the screwed end of the pin. When the pin is in place the ends should be flush with the outer surface of the fork; the head end of the pin has a slot for turning with screwdriver, as shown in the figure. The spoon should move freely on the pin and have no side movement, else it will give a disagreeable rattle on the road. The spoon, after being fitted on its pin, is taken off and finished up, not for plating but for enamelling. On the back of the spoon (fig. 32, B) will be seen a pin to attach the lower fork end of brake-rod. The fork end, C, is neatly fitted to this pin, and a $\frac{1}{4}$ in. hole bored for a small bolt. The tubular portion of the brake-rod has already been noticed in the brazing process. It has only to be finished up for enamelling like the spoon. The solid rod, B (Fig. 35), is finished $\frac{1}{4}$ in. thick, and should fit neatly and slide freely in the tube, A. It is 9 in. long, including the forked head. This part is bought as a rough stamping, and has got to be finished for nickel-plating. The forked end has got to be fitted to the end of brake lever (A, B, Fig. 31). The fork is first filed with a flat file to receive the lever; the lever is then filed down to fit in tightly meantime. When fitted in, a $\frac{1}{4}$ in. hole is bored through both fork sides and lever to receive a bolt and nut, same as at spoon back. These bolts are bought for the purpose with neat hexagon heads and nuts. When the hole is bored as above, a piece of wire is driven into it and the fork part and lever filed up and finished together, which makes a neat tradesmanlike job. The set screw at E fixes the rod, B, at any desired height within the tube when adjusting the handle-bar.

We now tackle the brake lever (Fig. 31). This is 15 in. long and $\frac{7}{8}$ in. broad at the broadest part—namely, where it hinges to the lever lug (Fig. 26, page 356). It is about $\frac{1}{4}$ in. thick throughout its length, but at the right-hand end in the figure it is flattened out in the edge direction into a shallow spoon form, as a grip for the hand. When bought, the lever is a straight bar, and has got to be set. The end, A, B, has a double bend. This is necessary to bring it out in front of the steering-post, the lever being hinged directly under the handle-bar. At C the lever has to be bent to the same set as the handle-bar, so that the spoon part will be immediately under the handle, in the best position for gripping. This lever being fitted into the lug, D (shown full size, Fig. 26), has to be bored for $\frac{1}{4}$ in. bolt, as before described.

The spoon end of the lever is set downwards, as shown in A (Fig. 31), and this being done, this part—namely, the brake lever—is finished by grinding and polishing, or by filing, to be nickel-plated.

Fig. 33, A, B, is the lamp bracket and set-screw collar combined. This part may be neatly fitted to the top of the steering-tube. It is a steel stamping, and has to be finished up for plating, so it is not brazed, but fixed to the tube with two small flush screws. As will be seen from B, Fig. 33, a hole is bored through the bracket through which the brake-rod passes. The back part of this bracket is bored $\frac{5}{16}$ in. and tapped $\frac{3}{8}$ in. for the set-screw.

The adjusting cone ring, C (Fig. 8, page 168), here shown full size (Fig. 38, in section), is fitted on to the steering-tube before the lamp bracket at top; it also has a set-screw flush with a slit for a screwdriver. This part is turned and finished in the lathe, and is plated.

Now, having completed that part of our work, we will attend to the mud-guards.

The mud-guards are made of very thin steel, and are rolled to fit any size of wheel required, and in section like Fig. 39. The rear mud-guard is about a half circle, that for the front wheel being somewhat less than one-fourth of a circle. The front guard is fixed by a screw at its upper end hard under the fork crown, where a hole has been previously tapped and the screw fitted; it should at this part be an inch clear of the tire. The lower end is supported by stays (see Fig. 36). These stays may be round, flat, or half-round iron. I have shown them of half-round iron, as in section A. The ends have to be doubled in forging to get stuff enough to form an eye with a $\frac{7}{16}$ in. or $\frac{1}{2}$ in. hold, as the hub axle may require. The manner of forging these is clearly shown in the figure. This stay is made long enough to form the pair; it is simply bent in the middle to go round the *outside* of the mud-guard, and should be made of a length to stay the guard one inch from the tire, as at the upper end, as the neatness of a machine depends very much upon having the mud-guards concentric with the wheel tires.

The rear mud-guard is fastened to the frame at two points: first at the bottom bracket by a small screw to the tube; second, to the rear of the socket at upper end of the bent tube, D (Fig. 1, page 33). It is also stayed at two points by stays made exactly as the front guard stays. The inner ends of the stays are slipped on to the ends of the axles, and the whole tightened up with the outside nuts. This mud-guard should also be an inch clear of the tire throughout its whole length. The fact of the rear axle being adjustable by sliding in the slots does not affect the position of the mud-guard seriously, as the wheel being moved backwards or forwards in the slots carries the mud-guard with it, the stays being on the axle ends. The stays, where they pass round the mud-guards, are riveted by at least two small $\frac{1}{4}$ in. rivets, and filed off flush on the outside. The rivet holes should therefore be countersunk before riveting.

Fig. 40 is one of the adjusting pins of the rear wheel, full size (see Fig. 6, page 168, where it is seen in place half size). It is 2 in. long and $\frac{5}{16}$ in. thick. Its outer end presses against the axle ends where they are supported in the slots. When the pins are screwed to push the axle outwards, the slack of the chain is taken up, so as the chain wears and requires taking up these screws are brought into requisition. When, however, the axle has travelled out to near the end of the slots, a link must be taken out of the chain and the two screws wound back for readjustment.

I previously described the fitting of the bottom bracket bearings by bolting through the knuckle joints. They should now be fitted in together with the axle and its chain wheel: without the key, however, as yet. Now the rear driving-wheel is put in its place and adjusted to run in the centre of the fork tubes, otherwise to run in line with the bent tube in front of it. This being done, the chain wheel has got to be set exactly in line with the hub cog-wheel. This may be done by using a straight-edge or a taut string, or even a good eye. When the two wheels are got into line, the chain wheel is marked in its place on the axle, and the latter being removed from the bearings, the wheel is firmly keyed on.

It takes about 4 ft. of chain for one machine. This chain is provided with a small bolt and nut. This bolt fits the holes in every link, so that wherever the chain may be cut the bolt fits for joining. To fit a chain on a new machine, the rear wheel axle should be pulled in to the inner ends of the fork slots; when the chain is placed over the wheels and the ends placed alongside each other, it will be seen at once which link to remove. To cut the chain, both the rivet ends of the same link are filed down level, then punched out, and the bolt will fit the rivet-holes. The chain will hang loose, and has got to be pulled up by the

adjustment screws above referred to. It must be observed that for use the chain should not be pulled tight; the bottom half of the chain should hang a little curved when the upper side is taut, as when driving the machine.

If the cranks are bought in the rough, they are first bored to fit the axle ends, which should come through flush, and no more. I have shown in detail the two prevailing forms of cranks (Figs. 17 and 18, page 308). The cheaper crank is Fig. 17, keyed on; so it will remain a matter of choice which of the two sorts is adopted. The most approved length of cranks is from 6½ to 7 in. The outer ends of the cranks have a slot some 1½ in. long, to allow of varying the stroke of the pedals. The inner ends of the pedal pins slide in the slots, and are fixed at any desired place by a ½ in. nut with a washer behind it.

The pedals are generally bought ready-made and plated, and they may be plain or ball, according to the depth of the pocket of the buyer.

Pedals may be made up from the parts, however, as all the parts are sold by the dealers. In preparing the cranks for the pedals the slots must be filed out till the flattened end of the pedal pin enters, when it should move freely along the slot without shake. Then the cranks are finished up for plating or for enamelling, according to choice, although they are, as a rule, plated.

The foot-rests on the front fork may be plain pins fixed into the fork sides, and clothed with rubber, the pin having a small nut on the outer end to prevent rubber from coming off; or if the rubbers have close ends, they are cemented on to the pins with tire cement. The adjustable foot-rest is much preferred by many, as it may be placed on the fork side at any desired height. It is made of a steel strip about ½ in. broad, bent double and widened to clutch the fork side, where it is fixed at the back by a small bolt passing through both ends. The upper edges are serrated to prevent the foot slipping. They are nickel-plated, and sold in pairs at about 1s. 6d.

The step (Fig. 7, page 168) is fitted by screwing the tenon ⅜ in. and tapping the extension on the left rear fork; it should be screwed in tightly and filed off flush on the inside, as a nut might interfere with the hub.

If a rubber step is preferred, a plain ⅜ in. pin some 2½ in. long, with the outer end reduced and screwed for a ¼ in. nut, a piece of pedal rubber, or a foot-rest rubber, is placed on the pin, and a small washer and nut keep it secure.

Another kind of step is the loop, which is hung on to the end of the axle, hangs down about 2 in., then turns upwards, and has a round flat button for the foot to mount by.

We have now gone over nearly every part of our machine, with the exception of the saddle and spring. We have in the market the saddle and spring separately and the saddle and spring in combination.

When the saddle and spring are separate I use what is called a three-coil spring; the saddle is mounted on top of this, and it is in conjunction with this spring that the bracket (Fig. 37) is used. In the combination the saddle is stretched on a spring frame, having the bracket for the L-pin as

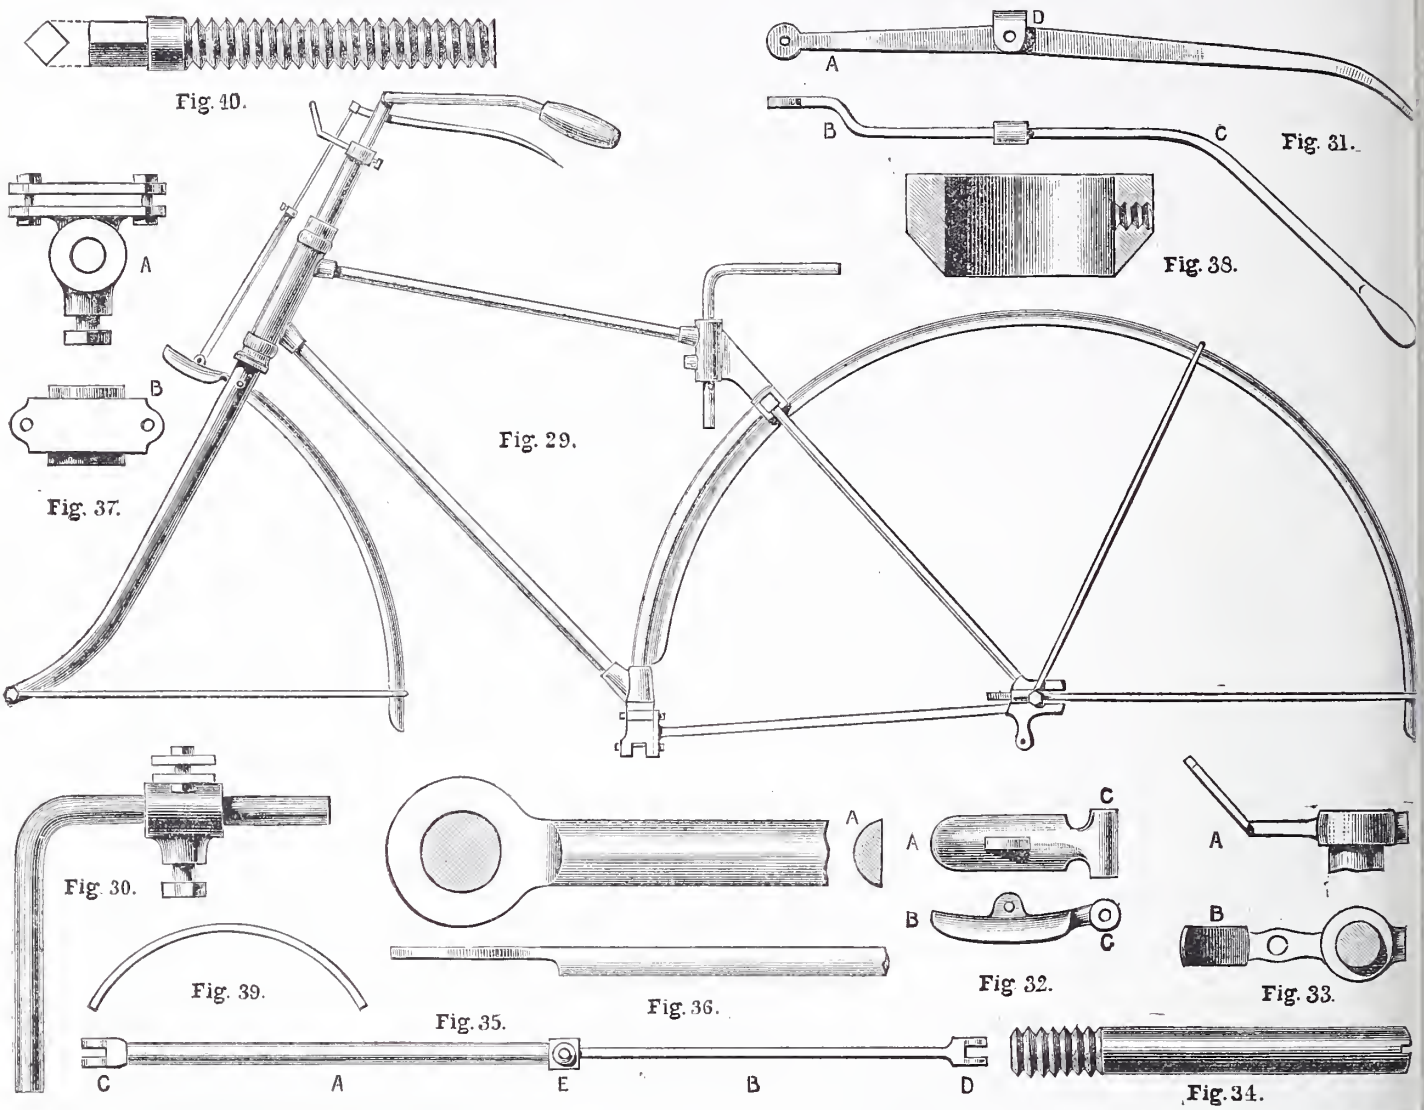

Fig. 29.—The Frame minus the Wheels (⅛ full size). Fig. 30.—L-Pin and Bracket. Fig. 31.—Brake Lever. Fig. 32.—Spoon. Fig. 33.—Lamp Bracket. Fig. 34.—Spoon Hinging-pin. Fig. 35.—Brake-rod. Fig. 36.—Mud-guard Stay Ends. Fig. 37.—Spring Bracket. Fig. 38.—Adjusting Collar. Fig. 39.—Section of Mud-guard. Fig. 40.—Screw for adjusting Chain. Figs. 30, 31, 32, 33, 35, 37 are ¼ full size. Figs. 34, 36, 38, 39, 40 are full size.

part of the under side of the frame, as in Fig. 1 (page 33). This combination is considerably dearer than the other, the cheapest being about 7s. 6d.

Having completed all the fitting, our next work will be the choosing and fitting the rubber tires, which I will leave over for the next article, which will be devoted to the consideration of the enamelling and the plating of the bright parts of the machine, as well as that portion of our subject already mentioned. Nothing will then remain to demand our attention except the final fitting up of the entire machine and the last touches necessary for its final preparation to take the road as a machine completed and ready for daily use.

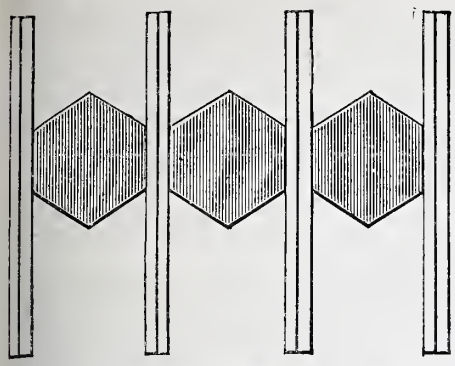

Fig. 84.—Laying out of Wires to be turned as in Fig. 83.

## WIRE-WORK IN ALL ITS BRANCHES.

BY JAMES SCOTT.

### Peg Latticing—Hexagonal Mesh.

Every day one meets with fencing along palisades, in front of poultry pens, along garden walks, etc., of the description represented in Fig. 83. This pattern is one of the commonest made use of, but it is being greatly superseded by the diamond crimped mesh. However, the hexagonal mesh is a very useful and strong description of work, and deserves the patronage it has received.

The hand method of working it is comparatively simple. The process is delineated in the progressive diagrams (Figs. 84, 85, 86, and 87). A number of hard wood or iron pegs, corresponding in number to the number of clear holes required in the work, are inserted across the bench, as shown in Fig. 88, in a straight line with one another, each peg being separated from the other each side by about the space two or three thicknesses of the wire would occupy, and each being hexagonal in shape, as represented in Fig. 89. The pegs must be the same size as the mesh required to be made.

An even number of wires of the proper gauge are laid, as in Fig. 84, on the bench. One pair will be on the outside of the end peg at one side of the bench, and another pair on the outside of the peg at the opposite extreme; while the remainder will be disposed of in pairs between the rest of the

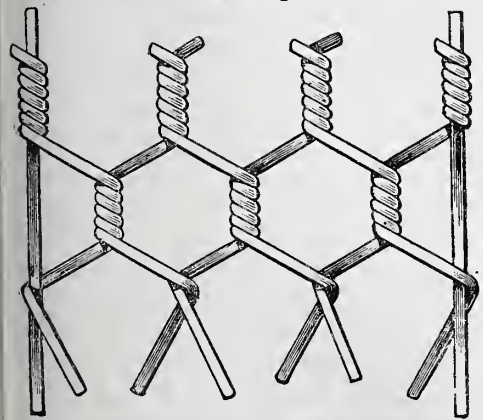

Fig. 92.—Diagram showing how Wires are crossed to obtain Diamond Meshes.

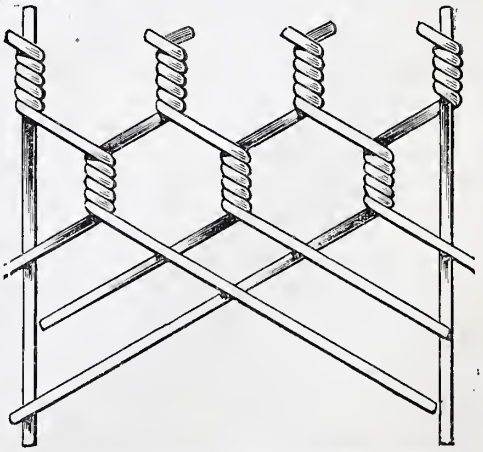

Fig. 93.—Another Mode of crossing Wires to obtain Diamond Meshes.

pegs. I have only used three imaginary pegs in my illustrations, for the purpose of economising the space at my disposal.

A wire bound round the bench can secure the wires temporarily by the latter being hooked on to it; or small staples can be driven into the bench, on to which the wires may be attached; or, in lieu of these means, the ends of them can be turned and driven into the bench. The object for thus temporarily securing them will be understood as I progress with my description.

The inner wire at one side, and the one nearest to it of the adjacent pair, are twisted by the hands or pliers, according to the toughness of the work, until the twisted section is in length equal to one side of the hexagon (Fig. 89); then the remaining single wire of the second pair is twisted in a similar manner in connection with the wire nearest to it of the third pair. So the operation is proceeded with until they assume the appearance shown in Fig. 85. The two outside wires will always remain in a straight line—*i.e.*, they will not follow a hexagonal shape, but merely be twisted round the others where necessary. The ends which have until now been secured to the bench must be twisted, and will appear as in Fig. 86. At this stage the work is placed over the pegs, as in Fig. 87, a half mesh remaining outside the pegs at each end. It will be found necessary to remove one of the pegs occasionally to permit this to be accomplished.

When in the position last mentioned, the same process is followed as described above, a wire in each pair being twisted around the wire nearest to it in the pair close by. Every time they are twisted the same number of turns must be given them to bring all twisted sections to the same length as each other. By following these means, any length of netting or latticing can be made; the finished portion being rolled when it becomes a source of inconvenience. It will be necessary to use a weight to keep the work steady.

When the ends of the wires are reached, they can be joined on to others in order to continue the length. We will suppose that the ends are shown in Fig. 86 (A). The ends of the wires to be continued with these are indicated by B (Fig. 86). Each separate wire of B is twisted around the wire facing it in A for a certain distance, which certain distance must be just so far as will allow the sides of the mesh, when the pegging is continued, to be of clear wire as the remainder is composed of.

There are other variations of the same method, the results of which present a very different aspect—at any rate, in some opinions. I am of this opinion, for I should most decidedly say that the meshes shown in Figs. 90 and 91 are each different in appearance to the other, and both present a different aspect to the one we have just previously given attention to.

We will take Fig. 90 for our present consideration. In this mesh a single row of diamonds is introduced between every two, three, or more rows of hexagonals. The hexagonal pegs will serve for this description of work every bit as well as for that of merely hexagonal ones. To effect the difference, it is only necessary to allow the plain wires to cross one another, as in Fig. 93, when a row of hexagonals is finished, instead of placing them in a continuous straight line as is done in Fig. 85. The wires, where they at first cross one another, are then twisted with two turns, again coming straight, as shown in Fig. 86. Here they are proceeded with in the same manner as at the start of the work; each pair where they cross being twisted, as in Fig. 92.

Dealing with the mesh in which there are two rows of diamonds, it is quite suffieient to say that the method of working will only differ from the others noticed in that the wires are again crossed when one row of diamonds have been completed, and are treated in exactly the same manner by being twisted twice, and then continued in a hexagonal mesh.

There are other varieties of this mesh. Sometimes the twisted sides of the hexagon are lengthened to twice the distance occupied by the plain sides; but those which I have endeavoured to make clear to the reader will convey an idea of their construction.

Very many workmen were in the habit of using but one peg to make this kind of netting. It is true that "experience teaches;" and that is the reason why they could twist the wires to form a hole, take them off the peg, make more holes, and thus finish the work.

I may in a future paper describe the peg latticing machine, but I do not absolutely promise to do so. There is a gentleman in Norwich who, I am given to understand, enjoys what might reasonably be termed a monopoly of the manufacture of peg latticing—at least, he supplies wire-workers all over the kingdom with this description of goods, the majority of warehouses or workshops preferring to purchase it from him to manufacturing it themselves.

## PORTABLE BOOKCASES.

BY H. J. L. J. MASSÉ.

ADVANTAGES OF PORTABLE BOOKCASES—OXFORD BOOK-BOX FOR READING MEN—WRITER'S BOX-BOOKCASE—TWO-SHELVED BOOKCASE—ALTERNATIVE METHOD OF CONSTRUCTION—HANGING SHELVES.

THOUGH a portable bookcase is to many persons quite unnecessary (and they may pass over what I have to say on the subject), still, on the other hand, there are many people who, when away from home, cannot, from the nature of their calling, manage to be absolutely without a few books on some special subject or other, or a few books of reference. Many persons are deterred from transporting books with them on their travels because of the damage often done in transit to their mute but trusty friends, and also because of the difficulty of placing them conveniently for use and of securing them from over-inquisitive eyes.

In my own undergraduate days at Oxford a favourite plan for reading men was to have a box with the inside fitted with movable and easily adjustable shelves. This book-box being made of deal as a rule, or pine, fitted with a lid sliding in a groove, could be fastened with a till lock or one or two screws and sent home or to one's destination during vacation, reading parties, or what not, by goods train.

This form of bookcase is, in my opinion, the best for actual travelling, though others may be considered more portable, and can be put together by anyone who is at all clever with his head and fingers at a very small cost. While I am writing I have by me a mahogany box which I use as a book-box. It measures 16 in. by 9¼ in. by 6 in., and will hold about thirteen or fourteen books of average thickness not exceeding the size known as post octavo. It is a cigar box with a sliding lid, and was bought long ago from a tobacconist when I was a boy and delighted in having a box to keep my treasures in. After its partial covering of gaudy paper had been removed by soaking, it was French polished, and finally I fitted it with an American window-sash lock. These locks, by the way, slightly resemble the well-known Yale locks in the shape of their keys and general construction. The box can easily be carried by means of a luggage-strap or brass drawer handle.

This form of box-bookcase can naturally be varied in size to suit the wants of any person who may desire to make or possess one. I have seen them 3 ft. square by 8 or 9 in. in depth, and the quantity of books they held was surprising. Larger sizes than this are made, but they are apt to be rather cumbersome, and require to be structurally heavier.

Another kind can be made by anybody skilled in turnery, or could be made by using up banister rails. The mode of construction is as follows:—After choosing and preparing the pieces of wood for the shelves—the size must be left to the maker of the case—and settling on the distance to be allowed between the shelves, two narrow strips of wood, say 2 in. wide and ½ in. in thickness, are to be screwed on at the back of the shelves: about 6 in. from the ends of the shelves is a good distance to fix them. These two strips or slips will serve to keep the shelves rigidly in position (if the shelves are cut out to receive them so much the better), and being serewed in can be removed in a few moments. For the front of this bookcase small columns can be turned and fitted with the two-ended screws used in fixing the ends to curtain poles. These screws will of course pass through holes in the shelves; at the lower end of the columns they may be screwed into knobs which will serve for front feet if the bookcase be designed for standing on a table; at the top ends the knobs may be made slightly more elaborate.

So far I have described the construction of a two-shelved bookcase—*i.e.*, one which will hold only one row of books—but the principle may be extended, and an upper tier for smaller books added as occasion may require. There is scope, too, for design in the shape of the shelves, which may range from the severely rectangular to the what I may call lodging-house mantelboard pattern.

Yet another way of knocking together a small bookcase would be to make the slips for the back slightly stouter, and hinge the shelves on them in such a way that they shut down closely on to the slips for travelling. The front columns would fit in as described above, and would take up very little space in any box or bag.

There is a way of suspending a shelf or set of shelves from the wall with strings or cords, the shelves being adjusted in their places by means of knots. These shelves are certainly portable, but they are often unsightly and untidy because they hang, as they are made, crooked, it being not the easiest thing in the world for anyone new to the work to make a firm knot at a given point in a string or cord. A good way in making them is to use chain, strong in proportion to the weight to be carried, remembering that a chain is in no part stronger than its weakest link. The distance between the various shelves may be regulated by neat little pins of stout wire passing through the links just under the shelves to be supported by them.

It is advisable, whether cord or chain be used, to fix a thin strip of wood at right angles to the shelf where the holes for the cord or chain are made.

## MEANS, MODES, AND METHODS.

### An Excellent Brown Stain.

A brown stain, which can be used on all kinds of wood, and made a lighter shade if desired simply by the addition of water, can be made in the following way:—Take vandyke brown ½ lb., a pennyworth of burnt sienna, and 1 lb. of washing soda. Add two quarts of water, and boil for twenty minutes. This stain only costs sixpence for two quarts, is very strong, and will stain floors light oak, dark oak, and walnut colour; and is, in fact, about the most useful stain we can possibly have. H. H.

### Springs for Gluing Purposes.

Very useful articles can be made from old sofa or chair springs by simply cutting them off in rings, by which means we shall get large and small sizes, suitable for all jobs.

Fig. 1. Fig. 2.

Fig. 1.—Spring. Fig. 2.—Method of using Spring.

The method of using them is exceedingly simple. Take, for example, a thin slip of hard wood is to be glued on to a rail, as in the case of drawer work. After rubbing out the glue, pull on a few springs, taking care not to open them too much (but just letting them spring on, as it were), and it will be found they will hold the joint close while the glue sets. A little thought will discover lots of jobs (where glue is used) that the springs will be of great use for. Fig. 1 shows a spring cut off, and Fig. 2 the method of using the spring. H. H.

## HOW TO MAKE AN INEXPENSIVE GLASS DOOR-PLATE.

BY FRED JOINT.

Whilst looking over the pages of Work, men of limited means have, as a rule, first to consider the cost, or probable cost, of articles in the making. No doubt there are many that have fancy articles in their minds, only waiting for the "necessary" to come to hand to commence operations.

Those who had the good fortune to visit the Work Exhibition, doubtless, carefully examined the "Waste Product" department. In essays exhibited by me was one on the treatment of broken china ware for window-boxes, plant-holders, etc.; and another, cork dust (the packing from grape barrels), for gardens, ferneries, etc.; and now, to complete effects, I herewith give an artistic glass door name-plate, at a trifling cost to make.

First get a piece of glass cut a little under the size of plate required, and then draw your name (or the name you wish) on a piece of transparent paper. This must be drawn neatly and well to ensure good results, so if, however, you are not skilful in lettering, I advise the study and practise of articles in back numbers of Work on the subject, otherwise procure a copy of Vere Foster's Printing Book, which is sold by or can be got from any stationer, and gives several forms of lettering. When this is mastered, paste the edges to the glass, taking care to put the paper on the top, name upwards. Also be careful to see that it is placed even and straight with the centre.

With a fine camel-hair brush and some brunswick black, follow out all parts *not to show*. When this is dry, trim off any surplus black with any sharp-pointed instrument, and clean the glass with a fine rag, then with gum or glycerine cover the name part left, and again leave to dry or get "tacky." Now cover over with gold leaf, carefully laying it down even and straight, so that when the paper is removed from the front you find the name appearing boldly in gold with a relief of deep black. Varnish the back to prevent damp getting to the gold, and frame in the usual way, staining the frame to match your door.

A more elaborate method is to shade your printing with white and blue, or white and brown, giving the whole a bordering of about ¼ in. in gold.

Cost of materials, complete, about one shilling.

## A COMBINATION COAL-BOX AND MUSIC-STAND.

BY W. NEWTON.

Novelty and Utility of Design—Parts and Measurements — Fixing Sides — Bottom Board—Top Board—Brackets—Front—Uprights — Cross-rails — Music-stand — Its Construction—False Base—Coal-box and Receiver—Drop-handle—Quadrant Stay—Finishing.

This piece of furniture I introduce to amateur carpenters as a novel design concerning the combination of the coal-box and music-stand. The plan on which the former is made is not new, though I believe the manner of fixing the coal-receiver and the front is not common, and more simple than hanging the coal-box to the sides by means of swivels or swing joints. However, this does not much concern the amateur, providing he can get a design that can be worked out with comparatively little difficulty.

This particular piece of furniture is very easy to make, and yet, if carefully put together and nicely finished, is a very creditable article for either dining or drawing-room—in fact, anywhere where the piano may happen to be, as it naturally would be in a room where there is also a fireplace. One is apt to connect the piano with music when speaking generally, though, of course, it is not necessary to have a piano to have music; but this is drifting away from my subject, and I will call my readers' attention to Fig. 1, which shows a general view of the furniture in question.

The measurements are as follows:—Bottom board, 18 in. long by 14 in. deep, of ⅝ in. or ¾ in. wood. Sides of box, 2 ft. high by 12 in. wide, ¾ in. thick; the top board 21 in. long, 13 in. wide, ¾ in. thick. The wood used would possibly be one of the following:—oak, mahogany, walnut, pine, or ordinary deal. Personally, I don't aspire to either of the first three-mentioned, as a rule; first, because of the expense, and secondly, because I am not a good French polisher. Nor do I think, from my own experience, that many amateurs are; and such woods to look really well, and to repay for the cost, require polishing, so I generally stick to yellow pine when I want a natural coloured wood, and varnish it well; or common deal when the article is to be painted or enamelled, and so think the question of the material to be used must be left open, to suit the taste and pocket of the amateur.

The sides are fixed to the bottom by screws from underneath, and should have a clear space of 13½ in. between them, and also leave a margin of 2 in. of the bottom board in front. This will bring the sides flush with the bottom board at the back, the idea of the margin in front being to prevent the possibility of the furniture tilting forward when the coal-receiver is pulled out for use (see Fig. 2), to which I will refer again later on. The top board, A, is screwed on to the sides in like manner, overlapping them in front 1 in., and each side about 3 in. Four fancy brackets, 4 in. by 3 in., as shown supporting the top board, are more for finish, so need not be fixed very firmly; ½ in. wood being used for these. The front of box must be of substantial thickness—certainly not less than ¾ in., as it will have to stand the weight of the coal-receiver, and should be "made up:" by which I mean, not cut out of a single board, but having two uprights and two cross-rails. The uprights are 4 in. wide; the cross-rails 6½ in. This will leave an open space in the centre, measuring 11½ in. by 5½ in., to be filled in according to fancy. A good plan is to get a hand-painted tile, 12 in. by 6 in., or two 6 in. fancy tiles of some delicate tints, letting them into a rebate at the back ½ in. deep, the space admitting of a ¼ in. margin on all sides.

The uprights and cross-rails are, I need hardly mention, mortised and tenoned; and every amateur will know how to set about this who knows anything at all about carpentering, so there is no occasion to go more into details. And in making the front, or door, as I shall call it, it is as well to let it be full large, so that when fixed together it can more easily be squared up and fitted into its place, two thin fillets being screwed to the sides of the box for the door to shut against. Two strong brass hinges, 2½ in. long, are next let into the bottom edge of the door, so that they are flush with the surface when shut together (the knuckle edge being outwards); then screw them on to the bottom board, and this must be done before the back is fixed on. The back is of ⅜ in. wood, the grain running horizontally, and screwed on to the sides at back. Referring again to the door, the width of the uprights and cross-rails if left plain would sink the centre panel into insignificance, so I found a fancy moulding, 1 in. wide, mitred at the corners, and fixed on about 2 in. from the sides, and 3 in. from the top and bottom, greatly relieved the flat appearance, the moulding being fixed on with thin glue and needle points.

So much for the coal-box; but before proceeding to explain the music-stand I offer a suggestion for a false base, should the amateur consider the furniture not high enough, as it will not be higher (as shown) than about 3 ft. 9 in. In Fig. 3 I give a plan for a false base, which can be made up as follows, after the sides have been fixed to the bottom board:—Prepare three pieces of wood 4 in. wide, one piece ¾ in. thick, two pieces 1 in. thick, of sufficient length to form the front and two sides; and as the corners are mitred, this must be allowed for when cutting out the pieces. In Fig. 4 I give a section, showing how the base is made up. First, a piece (A) ¾ in. thick, with the front edge rounded, is screwed on to the

bottom board; B is 1 in. thick, with front edge hollowed and screwed to A; C, 1 in. thick, front edge rounded and screwed on to B. All screw-holes to be well countersunk, so that each piece screws flat against the other, having the appearance of a solid moulding, and all corners to be mitred. By referring to Fig. 4, it will be seen that the base projects slightly beyond the bottom board of coal-box. I have recently fixed a base of this sort to mine, and am pleased with the result, so that I think others may feel inclined to do likewise. The lining for the coal-box or coal-receiver I will refer to further on, and proceed now to explain the top part for the music-stand; and in so doing I must refer my readers to Fig. 5, which shows the uprights, that are the main and sole supports for the shelves and side pieces. The uprights are 1 ft. 9 in. long, of $\frac{3}{4}$ in. stuff, $1\frac{1}{4}$ in. wide, the front edges being beaded, and a groove, $\frac{5}{16}$ in. wide, $\frac{1}{4}$ in. or $\frac{3}{8}$ in. deep, cut down the centre. This is done by the aid of the "plough;" but in the event of the amateur not possessing this particular plane, a simple method is to get a marking-gauge, and set it so that when marking from both edges of the wood it will leave a space of $\frac{5}{16}$ in. wide in the centre. Then lengthen the marker, and by filing it flat, like the head of a spear, it will form a cutter sufficiently good to cut in the required depth; then, of course, a $\frac{1}{4}$ in. chisel will take out the centre. The uprights should then be screwed to the *back* of the top board, A (Fig. 1), 1 in. from either end; but, before fixing them, grooves should be cut in the top board to correspond with those on the uprights, and in a line with the same, for the side pieces, B, to fit into; and should be 9 in. in length. These grooves can more readily be cut out with a chisel, as they are "cross-grain." The shelves and side pieces should next be cut out, the former being of $\frac{3}{4}$ in. wood, the latter $\frac{3}{8}$ in. thick. Shelf E, the lower one, is 21 in. long, 10 in. wide; shelf D, the top one, 1 in. less in width. These are grooved on both sides, to take the side pieces. The grooves underneath shelf E are 9 in. long; the grooves between the shelves that hold the side pieces, C, are 8 in. long; and those on the top shelf, for the side pieces, H, are 7 in. long; all grooves, of course, being in a line with those on the uprights. The side pieces, B, are 8 in. high, when fitted, so should be cut $8\frac{1}{2}$ in. by $9\frac{1}{4}$ in. long, to allow for letting in; and those marked C are 7 in. high and 8 in. long when fitted, taking care that the grain of the wood is vertical. The top side pieces, H, are cut out to match the four brackets under the top board, A, and the height of them can better be judged after the shelves and other side pieces are fixed, the latter being glued into the grooves; and the former, in addition, should be strengthened by screws through the back of the uprights. The back, G, only extends down as far as the top shelf, and can be of thin wood, say, $\frac{3}{8}$ in., which is screwed on to the uprights at back, the top corners being level with the tops of the uprights, the points in the centre about 3 in. higher. A moulding or beading, $\frac{3}{4}$ in. wide and $\frac{1}{3}$ in. thick, makes a finish for the back, and is fixed on by screws from the back. The knobs on the top of the uprights can be of wood or metal; but should the amateur not possess a lathe, he can get some very effective brass knobs, such as are used at the ends of picture-rods. And, in conclusion, I would suggest that all edges showing which are drawn as square should have a beading on them, which is easily done with the "bead-router" so much advertised. The beading helps to relieve the appearance where the wood is required to be thick—such as the shelves, for instance—for, being intended for sheet or bound music, they have to stand a good weight if full. To prevent the music slipping through at the back, three laths, 1 in. wide and $\frac{1}{2}$ in. thick, should be screwed to the shelves and top board, A, at the back; and they also help to strengthen the stand.

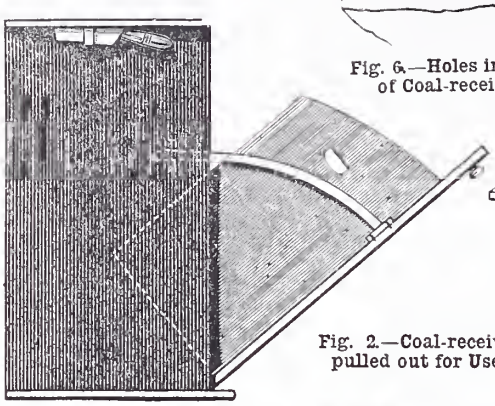

Fig. 2.—Coal-receiver pulled out for Use.

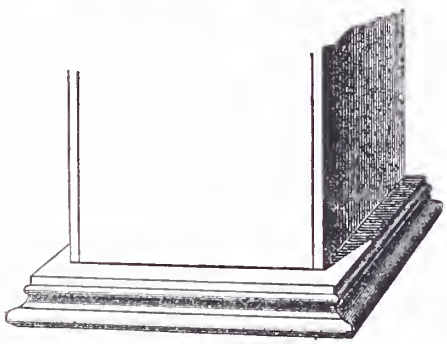

Fig. 3.—Plan for False Base.

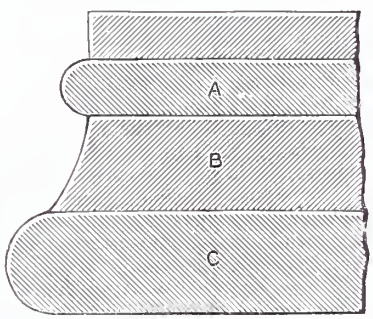

Fig. 4.—Section showing how Base is made up.

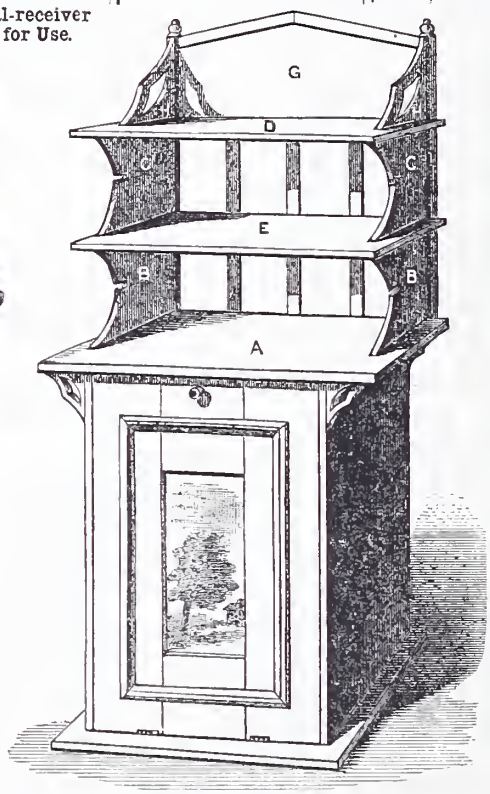

Fig. 1.—General View of Coal-box and Music-stand.

I now refer the amateur to Fig. 2, which is a section of the coal-box, and shows position of the coal receiver when pulled out for use. The receiver should be of the following size (strictly *outside* measurements):—Height at front, 18 in.; ditto at back, 15 in.; width, $11\frac{1}{2}$ in.; back to front, 10 in. This, of course, can be made of wood, but I would strongly advise the amateur to get one made in galvanised iron, as there is no fear of rust through wet coal; and an iron one will last a dozen wooden ones. It is hung on to the door, and should have two holes cut in the front, as shown in Fig. 6, the same shape as mirror-plates, so that it can be easily taken out, if required, for filling. Two drop-handles of iron wire should be fixed on the sides, either in or outside, for the purpose of lifting. Two stout round-headed screws, 1 in. long, are fitted in the door as far as they will go without appearing through, and the receiver hung on these. To hold the door in a proper position when opened to get the coal out, what is known as a quadrant stay should be fixed on one or both sides, if necessary. I endeavour to explain what I mean in Fig. 7, and the amateur will probably have to get it made either in brass or iron. The plate A is a fixture on the stay, and is screwed to the door; the plate B is a guide for the stay, and is screwed to the side of the coal-box. The end of the stay is turned up slightly to form a stop, and this coming against the plate B will prevent the receiver from coming out too far. So

in case of two stays being used, they must be handed—*i.e.*, one right and one left hand. A small piece will have to be cut out of the fillets on the sides, to allow for the stay moving in and out; and there is a space of 1 in. allowed either side, between the receiver and side of coal-box, for the stays. A strap of brass or hoop-iron screwed inside to the top board will hold the coal-scoop; and this, I think, completes the handy piece of furniture, with the exception of a small brass knob to open the door with. The weight of the receiver and its contents will be sufficient to keep the door closed. However, a small spring catch could be fixed on the top edge, if thought necessary. As to the finish, this will entirely depend upon the kind of wood used, and also upon the taste of the amateur; but I offer two suggestions. If made of yellow pine, which can be obtained nearly or entirely free from knots, a good way is to size the wood, and when dry, sand-paper it well, being careful to remove any roughness; then put on a coat of best copal varnish (dark oak), and when it is hard, sand-paper again, and apply a second coat. This will have the desired effect of giving a fine bright surface, and will show up the grain of the wood. I have done this with other pieces of furniture that I have made, with good results. I don't recommend spirit varnishes at all; they are cheaper, but not lasting. If ordinary deal has been used, the best plan is to enamel the furniture, but first it should be primed with a coating of white lead, turps, and a little red lead to harden it. This soon dries, and should then be sand-papered, and a coat of ordinary paint put on, consisting of white lead, turps, boiled oil, and a little driers. If the amateur mixes his own paint, he should always strain it through some fine netting or similar material; otherwise, it will not leave a smooth surface. On this the enamel can be put, the colour of which I leave to the maker.

Some of our readers may not care to have the coal-box surmounted by a music-stand, being unable to play. Under such circumstances a small revolving bookcase, or set of bookshelves that can be turned to suit the need of the owner, might be substituted for the music-stand, being extremely simple in construction and easily made, or the top might be finished to form a box-table, after the manner of the pretty little box-table described in a recent number of Work. If these are not liked a newspaper rack could be placed above the coal-stand, or the pedestal may form a stand for a bust, or be utilised as a jardiniere.

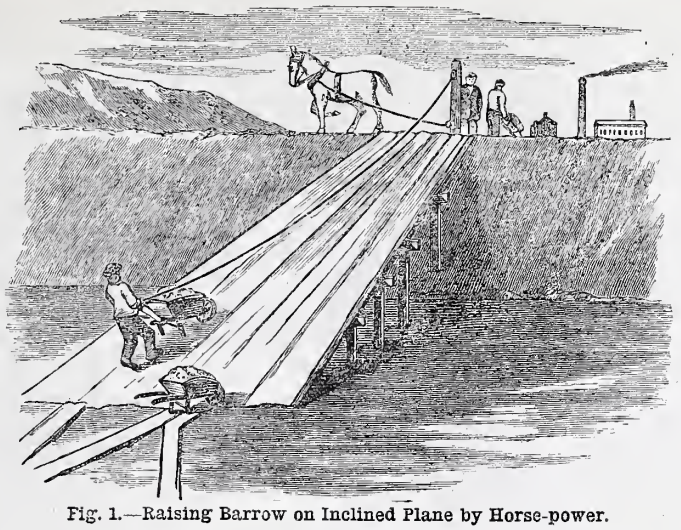

Fig. 1.—Raising Barrow on Inclined Plane by Horse-power.

## LABOUR-SAVING APPLIANCES ON THE MANCHESTER SHIP CANAL.

BY P. B. H.

Most of the readers of this paper will have come across descriptions of, if they have not seen, the large American diggers, which, with two scoopsful, load a contractor's waggon, or the powerful steam excavators, both German and French, which are incessantly at work on the above vast undertaking, now happily nearing completion, and which save such a vast amount of manual labour. In fact, they save so much that it would have been impossible to have constructed it without their aid. These great machines have been described so often and at such length in so many papers that I shall make no reference to them here. There are, however, in odd nooks and corners various labour-saving devices of a smaller kind, employed where the larger machine could not work, and which I will here endeavour to describe.

One of the first devices I saw, and which I have illustrated, is shown in Fig. 1, where a docile horse pulls the loaded barrow and man up an inclined plane formed of boards laid on temporary staging, the incline from the bottom of the canal to the top of the bank being too great for a man alone to wheel the loaded barrow up it.

One man attends to the incline, the full barrows being brought to him and the empties taken away below, while, on the bank, the full ones are removed and the empties brought to the top. Suppose a loaded one is below; the man slips over the handles a board perforated with two holes for that purpose, and to the centre of which the end of the hauling rope is fastened. The man now lifts the barrow in the ordinary way, but, instead of pushing it, he has only to hang on and guide it while both are drawn up by the horse, which starts at the word of command, and stops when it feels the tension on the rope diminish by the load reaching the top; it then turns round and walks back to the starting-point ready for the next load. The man now removes the board and hauling rope to one of the empties and proceeds, generally by sliding to the bottom of the incline. Should his velocity increase beyond safety pitch, the boy at the top puts the brake on the rope, which passes from the barrow over the pulley in the top of the post, then down to a swinging pulley near the ground, and then to the horse. It is really wonderful to see how expeditiously the work is done.

In certain cases hand-carts were used instead of barrows on these inclines; the proceedings were otherwise the same as in the preceding case.

A somewhat similar plan is used for raising the building materials for some arches in course of construction which had almost attained the necessary height of some seventy feet above the surface of the canal. In this case the rise is vertical, the rope passing from the horse round the swinging pulley at the bottom of the scaffolding, up over the pulley on derrick, and down to the floor, where it is fixed on the barrow, which the horse, at a word of command, immediately hauls up to the top. The man on the building seizes hold of it and draws it inwards as the horse backs a few paces to allow the load to descend. The horse now quietly turns round and proceeds to its starting-point. It may here be noted that in all cases where the horse is used the feeding-trough is placed across its path to mark its limit, but even with this they seem almost human from the manner in which they obey the word of command, starting, stopping, backing, turning, and walking back to the starting-point with the utmost precision.

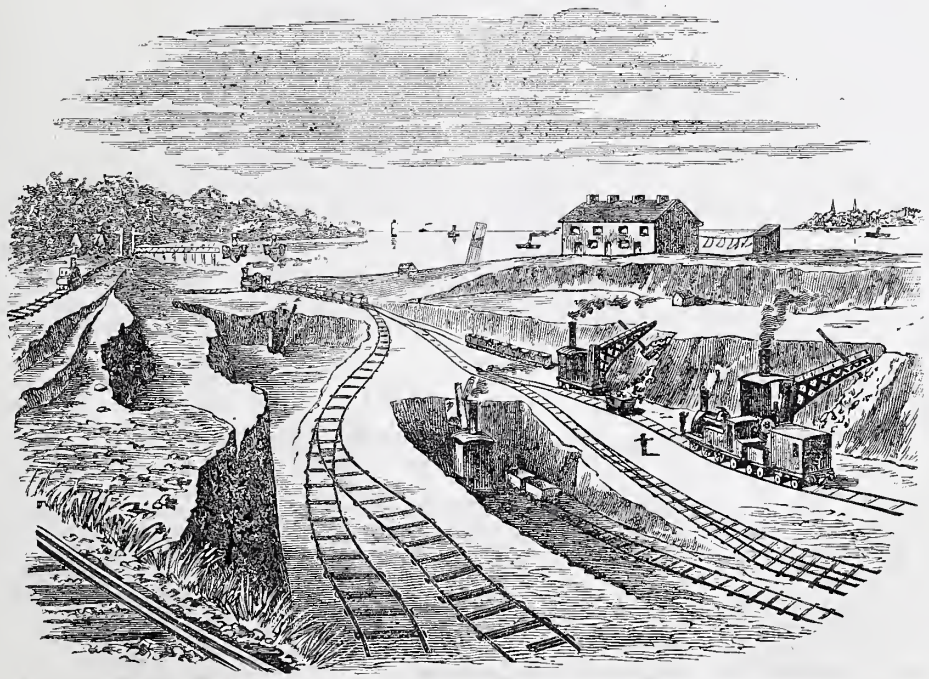

Fig. 2.—Mode adopted in excavating the Site of the present Eastham Locks.

Near some of the arches under construction there was a locomotive steam crane employed for lifting the blocks of granite for the masons. This, when not in use for them, was employed as an auxiliary to the horse in the preceding case for raising the barrows, which it did by travelling along its pair of rails with the end of the rope hooked to it.

Where material had to be raised a short distance and then taken further away to some other spot, the hand-carts or barrows were wheeled on to horizontal platforms, worked in pairs, travelling on inclined rails, one ascending while the other was descending. In this case the platforms were raised and lowered by a small steam engine.

Fig. 2 shows the excavations in progress, but taken some time ago, for the Eastham Locks, which have been lately completed and opened for traffic. The view is taken looking in the direction of Liverpool. The full depth is not yet reached in sketch even in the lowest pit shown.

The above are only a small proportion of the many devices in use, among which are concrete-mixers, a vast quantity of which is used. There are steam pumps, engines, and locomotives innumerable, and I should strongly advise anyone in the neighbourhood to pay a visit to this gigantic work.

## OUR GUIDE TO GOOD THINGS.

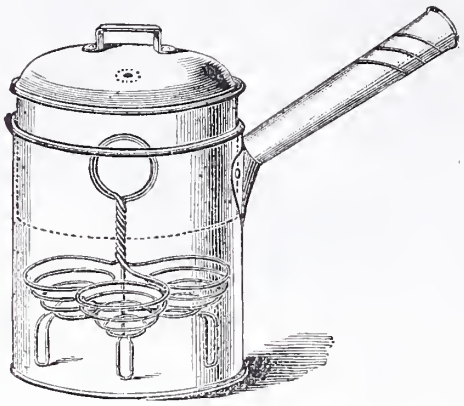
*** Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

### 63.—Planner's Patent Signal Egg Saucepan.

Not a very important kitchen utensil, perhaps, is the Patent Signal Egg Saucepan introduced by Messrs. H. G. Planner & Co., 1, Arthur Street East, London Bridge, E.C., and supplied by the inventor, Mr. Planner—who was for many years with Messrs. Deane & Co., the well-known ironmongers near London Bridge—or by any ironmonger or hardware dealer, at 1s. each, or 1s. 3d. post free. Its lack of importance, however, is counterbalanced by its great utility and unerring action, and the trouble it saves to all who boil eggs by its aid by saving them the trouble of watching the clock to see when they have been boiling for the regulation three minutes, or three minutes and a quarter, as some prefer to have it. The construction of the saucepan may be seen from the accompanying illustration. The eggs are put in the holder and deposited in the saucepan; just sufficient cold water is put in to cover the eggs, the deep-rimmed cover is put on, and the eggs are left to boil. Do not put in more than enough water to cover the eggs, for on this depends the generation of just sufficient steam, when the eggs are ready for table, to sound the whistle by the rush of steam through the hole in the lid, and declare the eggs as done. It should find a place in every house.

### 64.—The "Apollo" Picture-cord Grip.

The "Apollo" Picture-cord Grip is another useful invention, patented by Messrs. Smith and Davies, 9, Acton Road, Harlesden, London, N.W. I am unable to give the price, but this may be easily ascertained by writing to the patentees. The construction of the grip may be seen from Fig. 1 of the accompanying illustrations. From a substantial brass back plate projects a kind of box, whose interior is hollowed out in such a manner that the sides of the interior are slanting and slightly closer at the top than they are at the bottom. In this hollow or slot a couple of jaws are placed, grooved on the inner surface and slightly roughened to retain a better grip on the picture-cord when placed between them. The jaws are then held in position by a plate screwed across the opening, as



**Planner's Patent Signal Egg Saucepan.**

shown in Fig. 1. The jaws are furnished with flanges projecting laterally and in opposite directions from the top of each to prevent withdrawal from the box-like cavity when a downward pressure is exerted on them, and the left-hand jaw has a similar projection at the foot, which acts against the bottom of the other jaw and brings it up with the jaw to which it is attached when an upward pressure is applied. The grip is fastened on one side of a picture in the position shown in Fig. 2 by a screw through a hole made to receive it in the bottom of the back plate, and if the picture be large and heavy, another screw may be placed through the slot visible at the head of the back plate in Fig. 1. One end of the picture-cord is tied to an eye screwed into one side of the picture in the usual way, and the other is placed downward through the jaws of the grip. When the weight of the picture is thrown on the cord the jaws are drawn upwards and forced together by the pressure of the bevelled sides of the box on the similarly bevelled

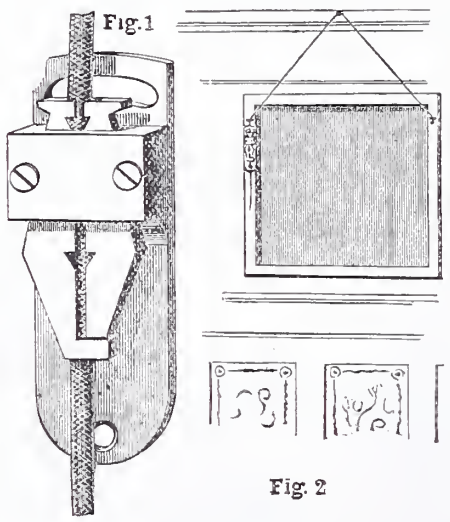


**Fig. 1.—"Apollo" Picture-cord Grip. Fig. 2.—Mode of Attachment to Back of Picture.**

sides of the grip. If it be desired to adjust the picture, or raise it or lower it, as is often the case, all that is needful is to raise the picture with the left hand so as to take the weight off the cord, and then with the right hand to manipulate the cord until the desired height is ascertained. It is in this ready regulation of the height of pictures that the "Apollo" Picture Grip becomes doubly valuable.

### 65.—New White Developer.

Mr. G. W. Secretan, 210A, Tufnell Park Road, N., has sent us a sample of his "New White Developer," which we have tried, and find it well bears out his statements as to its value for developing snap shots and rapid exposures generally, and giving a good, clear, and brilliant image. In these days, when hand-cameras are so much in fashion, such a developer is, undoubtedly, a great acquisition. It can be used repeatedly, retaining its clearness and active properties for some time; of course, gradually becoming slower in its action until exhausted. Being in one solution, requiring only dilution with water, is much in its favour, simplifying the process, and ensuring a proper working solution without any trouble. We can recommend it to our readers with every confidence. It is sold in half-pint bottles at 1s. each. He also sends us a specimen of Dunmore's "Unique" Black and White Cloud Negatives, for which he is agent. These clouds are extremely delicate and rapid printers, and no two are alike, and are very effective. When added to landscapes where the sky would otherwise be a blank space, they have a wonderful realistic effect, and their price places them within the reach of all. For the future we should not see so many landscape pictures destitute of clouds. The Editor.

## SUGGESTIONS FOR WORKERS AND HINTS TO INVENTORS.

Hydraulic Propulsion.—The substitution of the screw or paddle by some method of hydraulic propulsion is still engaging a good many minds, and has recently been much discussed at the meetings of engineering societies, etc. We do not deem it likely that the speed hitherto attained of nine miles per hour is ever likely to be exceeded with the existing form of sea-going hull. But for extremely light draught steamers, such as are necessary for some of the tropical and Australian rivers, the fact that the machinery could be placed in any convenient position would be a distinct gain. Very light draught, again, would permit of a much higher rate of speed being attained in proportion to the power, while it, of course, entirely precludes the use of a screw and is not advantageous to a paddle-wheel. Breadth, too, has often to be taken into consideration in tropical river navigation, so that, on the whole, an effective hydraulic propulsion engine has a field open to it. The existing patterns must, however, be improved on, if the engine is ever to be adopted even for the restricted uses above specified.

Sheet Iron in Castings.—Some few of our readers do their own casting, and a yet larger number have castings made for them when fitting up small engines, etc., in their amateur workshops. It may interest them to know that American iron founders are adopting a simple system of strengthening castings, which renders them practically unbreakable either by extreme changes of temperature, such as sometimes occur in stoves, or by an accidental blow. This consists in placing sheet iron in the centre of the casting, even ¼ in. oven plates being found to be rendered safe against fire by this protection. It is estimated that a plate thus prepared possesses six times the strength of one cast without a sheet-iron core. As the breakage of brass castings is also an occasional source of annoyance, especially when they have to stand heavy jerks and strains, such as come upon boat-cleats, crutches, hooks, etc., it would seem worth experiment so as to ascertain whether they could be similarly strengthened.

Rapid Printing of Stereos.—A direction in which inventors could usefully set their brains to work is that of a rapid process for printing engraved blocks or stereotypes. The output of an illustrated journal is restricted by the fact that printing it by means of the continuous web has as yet been found impossible, and that the reciprocating motion has therefore to be adhered to. It certainly does not seem as if human ingenuity were unable to overcome the difficulty; but the machine has yet to be invented.

## SHOP:

### A Corner for Those who Want to Talk It.

*** *In consequence of the great pressure upon the "Shop" columns of* WORK, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* WORK *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—Letters from Correspondents.

**A Lathe Wanted.** — J. B. (*Leeds*) writes:—"There are lots of things I should like to make, and could make, if I had a lathe. I have saws, chisels, and gouges, but I want to do some turning. I noticed that in Vol. I. of WORK, page 444, under the *nom-de-plume* of STOKER, and under the heading of 'An Opinion of WORK,' a writer says he has made a lathe, and the materials in it only cost him about 4s. 6d. I should be very glad if STOKER would kindly enumerate in WORK the materials which only cost him that amount."

**Elizabethan Twist in Lathe.**—C. C. E. (*London*) writes:—"With a polite letter I have received from W. P. W. the specimen of work proffered on page 270. It is simply a double stranded spiral cut with a ¼ in. hollow drill, in no sense an Elizabethan twist, which may be described as a cylinder wound round an imaginary axis, the pitch of which may vary as you please, but the section is always circular."

**Saws and Lathes—Erratum.**—A. R. (*Scorrier*) writes:—"In my reply to A. C. (*No Address*) (see No. 125, p. 332), the passage halfway down should read: 'A machine with two belts will clean up from fifty to sixty spokes per *hour*,' not per minute."

**Fret Machine.**—NORTH JACK writes:—"Will you please note that in Fig. 2 (see WORK, No. 58, Vol. II., p. 91) the measure given is shown from top of foot to underside of table board, while it ought to he from the floor line to the top of table. The figures 1 ft. 7 in. should be 17 in., thus making the distance from floor to top of table 2 ft. 7 in., as given in Fig. 1. Also, that the distance between the uprights is 18 in., not 1 ft. 8 in. (see Fig. 1); and the table board is 23 in., not 2 ft. 3 in. The side bearing pieces are given too short in the timber list."—[You and all other correspondents submitting intricate drawings, involving such an array of figures as is contained in your fret machine and its parts, should be careful to indicate very clearly what dimensions, etc., are really intended.—ED.]

**Water Glue.**—J. B. (*Poole*) writes:—"I have tried this, and do not think it can compare with Le Page's fish glue for strength of joint; it also has the disadvantage of showing a line of colour at the joint darker and thicker than other glue. Nevertheless, being waterproof, it is a useful adjunct to the workshop."

**Brush-making by Machinery.**—W. B. (*Huddersfield*) writes:—"As a journeyman brnsh-maker I should esteem it a favour if you would give us some particulars on brush-making by machinery."—[I shall be glad to receive on approval any paper on "Brush-making by Machinery."—ED.]

**Birmingham Punch Trade.**—W. B. (*Huddersfield*) writes:—"If at some future time a chapter could be given to the Birmingham punch trade, I think it would be of considerable interest to many readers of WORK."—[I shall be happy to hear from any reader who can write on this subject.—ED.]

### II.—Questions Answered by Editor and Staff.

**Bear on Pole.**—OLRAC.—Your own common sense should tell you that if the bear is, as you say, constantly facing the man who walks round the pole, he is not going round the bear.

**Bookcase and Chiffonier.**—F. N. (*Manchester*).—If you purchase the Index to WORK, Vol. I., and that to Vol. II., you will find several designs which, with no great ingenuity, may be adapted to your requirements.

**Protection Stamp.**—HIGGINS (*Altrincham*).—The Government stamp on a provisional protection costs only £1. Duplicate specifications must, however, accompany this proper stamped form, and all must be done in strict accordance with the Patent Office regulations. A patent agent's usual charge for obtaining such protection is £3 3s. to £4 4s.—R. & C.

**Watch-making Tools.** — Makers' names and addresses have frequently been given in "Shop." Consult the Indexes of WORK, Vols. I. and II.

**Draughtsmanship.**—DEWDROP. — This subject will be treated in WORK shortly.

**Umbrella Silk.**—M. A. H. (*Richmond*).—Consult the London Directory for wholesale silk merchants. Any one of them will supply umbrella silk.

**Basket-making.** — J. K. (*Middlesbrough*). — When I receive papers on the subject they will appear. I await the convenience of the practical hand who offered to write on this subject, and whose offer was entertained by me. You may lead a horse to the water, but, as you are probably aware, you cannot make the said animal drink. In the same way you may accept proposals for articles, but you cannot make the proposers write.—ED.

**Camera and Banjo.**—D. M. S. (*Glasgow*).—Purchase the Index to Vol. II. of WORK, and you will find much upon cameras and banjoes.

**Glass Shades.**—R. S. S. (*Trevor*).—Glass shades can be procured of Messrs. James Powell & Sons, Whitefriars Glass Works, Temple Street, London, E.C. They have one very nearly the size you want, viz., 21 in. high, by 38½ in. by 13½ in., and which they quote at £4 10s., less discount for cash. If this would suit you, it would, I think, be much cheaper than having one specially made; I would advise you to correspond with them. I may say, for the benefit of those interested in electricity, that the above firm supply glass jars for Wimshurst induction machines.—W. E. D., JNR.

**Indiarubber Stamp Making.**—E. P. B. (*Penge*).—A paper on this subject will shortly appear.

**Violin Varnish.**—R. O. B. (*Edinburgh*).—Write to Mander Brothers, Wolverhampton; they will be able to supply you, or at any rate direct you to one of their agents who will do so. Several articles on violin making have appeared in the present volume.—B.

**Weights of Galvanised Iron Sheets, etc.**—OLD SUBSCRIBER.—A sheet of 24 gauge (6 ft. by 2 ft.) galvanised iron will weigh 14 lbs. or thereabouts; 22 gauge 17 lbs., and 20 gauge 19 lbs. You would not want to use much thicker than that, I suppose, though you do not state the size boat you want to build. I think you will have some difficulty in making a boat of this material. The worst thing about galvanised iron is its tendency to peel when seamed or worked, and whenever the galvanising peels off, it will soon rust. The best way is to galvanise articles after they are made, but in the case of a boat this would be rather awkward.—R. A.

**Magnetising a Clock.**—KENILWORTH.—I do not think it possible to magnetise the steel works of a clock simply by connecting the brass frame to a battery and bell, and using it as an electric time alarum. If an electro-magnet is used in or near the clock for any purpose, the steel portion of the works might become magnetised.—G. E. B.

**Electric Bell Jumpers.** — AMATEUR BELL FITTER (*Clapham*).—I confess to entire ignorance respecting "electric bell jumpers." Heat the soldering iron by any means at your disposal.—G. E. B.

**Sable Pencils, Glass Embossing, etc.** — M. T. C. C. (*Belfast*).—Prices of sable pencils (Brodie and Middleton's): lark, 5d.; crow, 7d.; duck, 9d.; goose, 11d.; extra goose, 1s. 6d.; small swan, 2s. 6d.; middle swan, 3s. 3d.; large swan, 4s. 4d. each, post free. To test a sable pencil, wet it in the mouth, put the point upon thumbnail, and twirl round; if it keeps its point it is good, if it opens or splits reject it. M. T. C. C. cannot have read my early chapters on sign writing or he would not have asked this question. I am sorry to say I cannot give any useful information on glass embossing and gilding on glass in this column; it would require several pages to do so. If the Editor thinks fit, I shall be glad to contribute some articles on the subject in the next volume.—H. L. B.

**Repairing Silver Umbrella Handles and Collars.**—H. L. (*Bradford*).—Very many of these mounts are so extremely thin that it will take a very good workman to make a decent job of repairing them. The way to set about it will be to get the mount perfectly clean, and then to solder it with silver solder. Many details on this matter can be obtained from answers in No. 46, page 732, Vol. I. of WORK, and in No. 111, page 92, Vol. III. If these answers do not make the matter clear, then write again, and give me the points on which information is particularly wanted; and also state what you know of soldering. The greatest difficulty is, I think, in getting the solder to run in the seam. Now, if that proves so, then it may be well to put pieces of silver across the seam, or else put a plate of silver on either the inside or outside to help to draw the solder across the join; but in very many cases it is simplest and cheapest to make a new mount entirely. I have not taken pewter solder into consideration, as no good workman likes to use it. If, however, it is to be used, then see that a good-sized plate is made large enough to well cover the join. And it will be better if it be made to form an ornamental addition. For example, if a hole is to he covered, a shield or lozenge-shaped piece would do. If a collar is to be added, then two lines near the edge may improve it, or it may be made into the form of a strap and buckle, etc. etc. Pewter solder is of no use by itself, whereas hard solder amply suffices for this kind of job as a rule. There is a book that gives many details of silversmiths' work. Its name is "The Silversmiths' Handbook," published at 3s. by Crosby Lockwood & Co., but it is intended for those that have already some experience in that kind of work, and would not, I think, help you much.—H. S. G.

**Overmantel.** — J. H. S. (*Romsey*).—An article describing a dressing-chest is in hand, and will shortly appear. It is one that you would have little difficulty in making after your experience with the overmantels.—D.A.

**Converted Fret Machine.**—J. L. (*Airdrie*).—Much has appeared in Vol. II. upon this subject. Consult the Index to the volume.

**Stripping Electro-plated Coats before Re-plating.** — TOMMY HEATH. — All good workmen strip off old coats of gold, silver, and nickel before re-plating the articles. Although the old coat may look smooth to the eye, it may not be firm, and we cannot he sure of the new deposit adhering firmly to the old deposit. If it is worn away in places quite smooth, those bare places expose the metal beneath, and this will form, with the coat, two elements of a galvanic pair when placed in the plating solution, the result being a loose deposit at the junction of the old coat. Again, let the old coat be worn off ever so smoothly, it will look patchy, and these patches will show distinctly in the newly-deposited coat. The few operators you saw at work at the Crystal Palace and elsewhere had not the conveniences at hand for stripping off the old coat. The operation was performed there for the amusement of the puhlic. I do not find the operation of stripping any more tedious than other parts of the necessary preparation. The whole process is fully described in "The Electro-plater's Handhook," pages 101-104.—G. E. B.

**Varnish for Bright Spokes.** — K. M. D. (*Harling*). — The best transparent varnish for bright spokes is the Silico transparent enamel, in 1s. bottles, with brush. It is put on with the brush. The best varnish for iron beds is the Club black enamel, 1s. bottles, or 12s. per gallon, wholesale; both the ahove from the Silico Enamel Company, 97, Hampstead Road, London, N.W.—A. S. P.

**Griscom Electro-motor.**—T. J. (*Warrenpoint*).—I am sorry to have to disoblige you and other readers of WORK, but really cannot see my way clear to describe and illustrate every part of a Griscom motor, in the narrow confines of "Shop," in such a way as to enable you to make one from the instructions and illustrations. This motor is most difficult to make because of its compact form, which necessitates the exercise of more than ordinary skill and patience to wind with wire, and fit with armature and commutator. There are better and even more powerful types of motors in the market, and these will receive my attention at no very distant date, when I may also have something to say about the Griscom type. The Leclanché battery is altogether unsuitable for working a motor. A book on electro-motors is in course of preparation, and will shortly be published.—G. E. B.

**Tinting Photographs.**—W. T. A. P. (*Portsea*).—There is no method of tinting photographs and opals with water-colours that can dispense with a trained knowledge of colouring and considerable practice, if the results are to be worth looking at. Procure a handbook on the subject and carefully read it; you will then see that considerable knowledge and skill are required to attain a passable proficiency. There are just the same manipulations required for these pictures as for any other. In case the photograph itself is to show and form the shadows, light tints of suitable transparent pigments may be applied. This is probably the most easy method of colouring; especially when the high lights are strengthened by the application of touches of opaque colour to impart solidity of effect. Another method formerly much in vogue was to apply powder colours to the flesh, with a suitable brush or stump, and put a flat tint of transparent colour over the drapery. To make passable pictures by this means did not require much practice; but it can he easily understood that pictures so coloured would hear no comparison with skilful water-colour painting. To give crude directions for tinting, first of all prepare the surface of the print by a wash of oxgall to receive the colour, then proceed to colour the flesh and lighter portions, finally the drapery, using a little gum in the deepest shadows.—E. D.

**Platinum Contacts.**—F. W. (*Addlestone*).—As the price of platinum has more than doubled during the last few months, and is now nearly equal to that of pure gold, you will get but a very small bit of No. 20 wire for a shilling. I therefore advise you, and other amateur readers, to use platinum foil for contact points, instead of platinum wire. A tiny piece can easily be soldered on to the tip of a screw, and will last a long time.—G. E. B.

**Pocket Accumulator.**—S. G. V.—(*Boro'*).—As I described these in my series of articles on "Model Electric Lights," I will not take up the valuable space in "Shop" by repeating the description, but must ask you to be good enough to refer to those articles.—G. E. B.

**Frame Gilding.**—G. A. H. (*Stockport*).—Smooth your frame free of dust, and give it a couple of coats of gilders' clay; when dry, brush over with gilders' oil of gold size, and let it remain for about twelve hours, when it will bc found just tacky; put your gold-leaf on with gilders' tip, and dab down with cotton wool. When dry, go over work with clear size; when this is thoroughly dry, it is ready for picture.—G. R.

**Adjustable Rebating Cutter.**—M. E. M. (*Heywood*).—The little tool mentioned in Vol. I., page 301, will do very well for cutting the rebate in an "oval picture frame, photo size."—ED.

**Ferrotype Photography.** — FELLOWS. — There are numerous one shilling handbooks published on the wet process. One by J. Wergo, of Berners Street, is perhaps as good as any. Any bookseller will supply them. The "Ferrotype" process only

differs from the glass process in respect of the material on which the collodion is spread—glass in one case, and enamelled iron plate in the other. Ferrotype plates being opaque, do not require backing as glass plates do, otherwise the finishing is precisely the same.

**Wood Carving.**—"UT SPES NON FRACTA."—Unless you are by trade a wood carver, or have a thorough knowledge of the art, there is no way in which you can earn money by it, as there is little demand for any but the best work. You might refer to WORK, Vol. II., Nos. 64 and 74, and try what you can make at "chip" carving, which is the easiest form of work, but I doubt whether you would find much of an opening in that way.—M. E. R.

**Polishing and Mounting Horns.**—PIP will find directions for polishing horns in Vol. II., page 440, No. 79. As regards mounting, he might cut out an oval in 1 in. board, cover it with plush, and screw the horns upon it.—M. M.

**Labels.**—J. G. N. (*Manchester*).—You should advertise in our "Sale and Exchange" column.

**Cyclometer.**—H. C. S. (*Ipswich*).—I am practically unacquainted with the mechanism and movement of the cyclometer; further than that, it is an instrument for measuring the distance travelled by the machine. They are now greatly improved, and can be adjusted to any size of wheel. The instrument is fastened to the revolving shaft of driving wheel, and every revolution produces a click which is indicated on the face-plate similar to a gas-meter. There are numerous different makes of the instrument, and I should think that unless your correspondent is a watchmaker or a working optician, the job would be too much for him; at any rate, he would need to have one to copy, and I rather think the parts could not be procured from a maker. The instrument can be bought at prices from 17s. 6d. to £2 2s. The "Signal" cyclometer is sold at 30s., and can be had of Wilkins & Co., 66, Holborn Viaduct, London, E.C.

**Setting out Dulcimer-Blocks.**—G. A. (*Parkhead*).—I expect you have worked your stuff to the full dimensions given, and consequently your back edge, including the moulding, measures 1¼ in. I intended to convey in my paper, when giving thicknesses, those usually accepted when speaking of them. Thus, ¾ stuff is ¾ stuff less the saw mark, and this, when planed on both sides, would be not more than ⅝ in. Again, it is recommended to make the moulding from "a piece of inch stuff rounded up and divided into four lengthwise." These, when cleaned, would not be more than ⅝ in. thick, which would leave the back about 1 in. in thickness, and allow sufficient room for the top strings. However, it will be easy for you to allow ¼ in. more at top in "setting out," and this should give you ample room, and the difference divided by 20, the number of notes will not be appreciable.—R. F.

**Clock Wheels.**—WATCHMAKER.—I am sorry to say I cannot give any information how to cut out a clock wheel from sheet brass. As a rule, I believe, they are cast and then filed out to finish. When I was an apprentice I know we used to get them in blanks cast—that is, just like your drawing. We used first to well hammer them to harden, then drill a hole in the centre, turn them down to size, and make a circle width of band, allowing for teeth; then finish crossing out, and cut the teeth. I would advise you to do the same. Send to the tool shops for the sizes you require, or you could get them already cut with the teeth and ready, with a little filing at the crossings to mount; or drill a hole at each corner of the crossings, and punch out roughly with a keen chisel and finish off. I wish I could give you an idea how to make a die or stamp, but I doubt if you could make it pay unless you went in for making them wholesale, as you would require powerful machines to do what you require.—A. B. C.

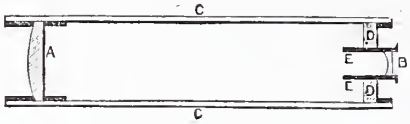
**Fixing Brass Plates.**—NAME-PLATE.—I gather from your letter that you are compelled to rivet your plates on the machines. Would not round-headed brass bolts, secured in rear or beneath, do as well as riveting? and which would look far more workmanlike. Another way would be to send the part of the machine on which the plate is riveted to the engraver, who would do his work as usual. The other alternative is to take a graver and cut out all the old spoilt wax, grind up some wax with gold size till liquid enough to run freely, fill the letters, and clean off when dry with spirits of wine. You will, perhaps, gather some further information from "Engraving on Metal," which appeared in Nos. 33, 38, 43, 45, and 48, Vol. I.—N. M.

**Japanese Stencils.**—M. S. (*Todmorden*).—I tried at the chief shops for Japanese stencils in vain; they were all out of them. Should I succeed in finding the address of a salesman, I will let you know in the pages of WORK. To cut them accurately would be less easy than to trace a design on your enamel (with carbonic paper) and paint it neatly by hand; so that unless you can come across the real thing, I fear you must be content to wait. If the Editor of WORK has room for them I would allow him to reproduce some I have belonging to me.—E. B. S.

**Chemicals for Portraits.**—J. D. (*Bethnal Green*).—Your best plan would be to purchase some elementary work on photography—say Burton's "Photography for Beginners" (1s.). You would then see what chemicals would be required. Any photographic chemist or dealer would supply you with reliable materials. The book can, of course, be obtained from any bookseller.—D.

**Camera.**—PHOTO.—Any photographic material dealer will supply your wants. A camera for ferrotypes would be fitted with what is termed a wet plate dark slide. The size is quarter plate, and the price varies, according to the quality, from 30s. upwards. A second-hand one could be bought at very much less. We do not make a custom of recommending any particular firms. The advertisement sheets of any photographic publication contain numerous addresses where all you require is supplied.—D.

**Telescope.**—W. M. (*Honiton*).—You will find very considerable difficulty in making a telescope "about 6 in. when closed"—that is, if you mean one having three or four draw-tubes. The difficulty would lie, not in the selection and arrangement of the lenses, but in the lathe-work connected with the tubes. I think I am right in assuming that you have not a lathe, but even if you have one, and can use it, you will learn more of the tube making and fitting by five minutes' examination of an ordinary pocket telescope than you would gain from a column of detailed instructions here. You say, "I do not want to make an expensive telescope; I want to see a good distance, and to be able to say that I made it myself." The latter is a very commendable desire, and you had, perhaps, best start to satisfy it by trying to make the least expensive and most simple form of all telescopes, the only form of instrument which, without sliding tubes, can be contained in 6 in. This form is called the "Galilean telescope." For its construction you will want two lenses. A plano-convex, say, 1⅝ in. in diameter



**Telescope.—A, Object Glass; B, Eye Glass; C, C, Tube (Brass or Paper); D, D, Disc of Wood bored to take the Small Sliding Eye Tube, E, E.**

and 6 in. in focus (the object glass), and a plano-concave, say, ½ in. in focal length. These should be arranged as in diagram: the one at a distance of about 6 in. from the other. The magnifying power will be 12, and is found by dividing the focal length of the object glass by the focal length of the eye glass—that is, $\frac{6}{\frac{1}{2}} = 6 \times 2 = 12$. You can increase the power either by obtaining an object glass of greater, or an eye glass of less, focal length. The cost of the two lenses necessary should not be more than a couple of shillings, if you use the common lenses. Of course, if you get achromatic lenses you will have to pay more. Your letter is in very general terms; and that is why I cannot definitely answer you. Will those readers of WORK who send telescope queries remember that the more information they give me the better information I can give them? They need not be afraid of making their letters too long.—E. A. F.

**Bending Brass Treads.**—P. D. (*Liverpool*).—I am not aware of any machine made specially for bending these step plates, or treads, as they are termed in the trade, but I can tell you a very simple way to do it, without anything but home-made appliances. Supposing that you have a bench with its front edge quite flat and true; then get a piece of wood cut out the thickness of the step that the plates are for, have one edge of it rounded off to what you want, and let it be about 3 in. longer than you want the treads to be. Bore two ⅛ in. holes an inch from each end, and screw it to the bench with two coach screws; bore two

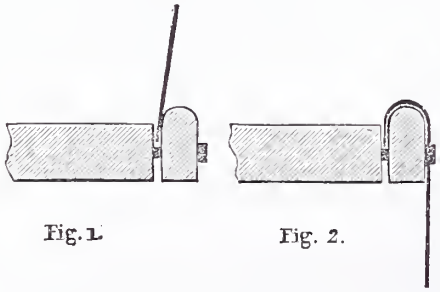


Fig. 1. Fig. 2.

**Bending Brass Treads. Fig. 1.—Section of Arrangement for bending Brass Plates. Fig. 2.—Showing Plate bent.**

smaller holes an inch away from the bolt-holes, and tack into the bench two wire nails for the brass to rest on as you slip it between the block of wood and the bench. These must be adjusted so as to give the right amount of turn under to the tread. The *modus operandi* will then be as follows:—Slip a plate of brass between the block and the bench; screw the coach screws tight, and bend down with both hands; undo the screws and take out. Half a turn of the screws will be sufficient to tighten and loosen the plates, and I think you will find it answer very well. Figs. 1 and 2 will still more plainly show what I mean. Of course, this will not remove dents; but I think you will find it a saving of time against the rollers, besides getting every plate exactly alike.—R. A.

**Patent.**—J. K.—I do not see anything in this to sustain a patent, nor do I think it would be upheld on a trial. There are some disadvantages. For instance, I do not see what is to hinder the sewer gas from flowing out through fresh air inlet. Also, should any pressure occur, the gas will be forced into the houses sooner than into the street.—F. C.

**Fret-saw for Lathe.**—S. P. (*Penarth*).—Where can you and your friends have lived if they don't know of the numerous "rigs" for fret-sawing on the lathe? You don't say whether you wish to buy or make one. You can buy one from the Britannia Company, Colchester, but it is an easy thing to make, and can be done in many different ways. I think your first step might be to get some of the catalogues published by dealers in fretwork materials, as besides the prices you would see many illustrations of tools, etc., from which you could gain new ideas. For instance, write to Messrs. Harger, of Settle, Yorks, sending six stamps; or to Messrs. Churchill, Cross Street, Finsbury, E.C., and enclose twelve stamps; you will get a delightful picture-book, richly worth the money, containing hundreds of illustrations of new American tools, etc. You can certainly utilise your brass face-plate by screwing a ¼ in. steel pin into it about ½ in. from the centre to drive the lower arm of the saw; but take a good look round first, and see what others have done, is the advice of F. A. M.

**Paint or Enamel.**—ANCONA.—There is no article of the above nature that will resist the continual action of soap or similar alkaline natures. "Bath varnish," which is specially made for re-painting, etc., insides of house-baths, is the most durable article you can use, without, as you remark, the firing process. If you use this for finishing your painting on tin surface, mix your paint itself with three parts of turps to one of bath varnish only—no oil or other driers—and then, when finished, leave it to harden as long as possible. For using on grained work, get "fine copal oak varnish." This will do for all ordinary purposes, excepting floors or furniture that is *sat upon*, for which "hard-drying" or "church oak" is required. Varnish should never be tampered with, especially by the novice. Adding oil will ruin it.—F. P.

**Dry Point Work.**—J. H. (*Bacup*).—The process alluded to in the photographic advertisement you sent, and which is termed "dry point work," is a method of working up enlargements. It is done by a needle-point brush, and consists of fine dots. There is one apostle, though I forget his name, who turns out splendid work, but he stands alone. The others are not, as a rule, very good hands.—F. P.

**Medium for Tile Painting.**—KILN BURNER.—"Fat oil" of turpentine is the most serviceable and least expensive of the various mediums used for china and tile painting. Other oils, possessing naturally the same qualities as the above product, are oil of aniseed, oil of tar, and oil of lavender. These necessary qualities are: First, that the medium should not "set" until sufficient time for manipulating the colour is given; secondly, that they shall be of a nature such as the firing process can properly carry away or disperse. The greater portion of tile painting—treating the art from the unprofessional aspect—is executed upon china or *glazed* tiles, and not upon "biscuit," as you desire. With the former, the firing can be done without much risk or trouble; but when it comes to *glazing* and firing the painting, you will agree that the process requires the convenience of a pottery works. The district from which you write suggests that you are able to command this latter aid, and as I presume you have some object in painting on "biscuit" direct, I therefore aid you as far as I can. Now, respecting the "tube colours," are they made for the purpose?—viz., kiln work. If not, then don't suppose you will do any good with them, since only such pigments as are *chemically* adapted for firing must be used. Assuming they are the right pigments, "fat oil" cannot be bettered, so far as I am aware, for the medium. Fat oil of turpentine can be made by exposing a little ordinary commercial oil of turpentine ("turps") in an open vessel and to an atmosphere both warm and dry. The fatness arises from the bulk of the "volatile" element or "spirit" evaporating, and leaving behind the resinous part of its nature. A table-spoonful may be exposed in a saucer—as in such a vessel it is largely exposed to the oxidising action of the air—until it thickens and diffuses itself all over the vessel. If the latter is stood in a second saucer, nothing is wasted, and there is least "mess." When once "fattiness" is obtained, the property is readily communicated to the fresh turps added thereto as the former is gradually required. Fresh turps is used to thin and spread the colour with after the pigment has been worked into a stiff paste with fat oil alone. Tile painting may also be done in water-colour by adding a little dissolved sugar to the *dry* prepared colours, using just sufficient to prevent the work from dusting off. Tile and china painting is not, as you are doubtless aware, a matter within the province of "Shop" to more than touch upon. It is an art, a difficult professional art, requiring knowledge of chemical properties as well as artistic ability and experience. I fancy it is your tube colours that are all wrong in chemical nature.—LONDON DECORATOR.

**Printing on Tin.**—CURIOUS.—A reply was given to this query in quite an early number of WORK, recommending the querist to inspect the various patent specifications relating to the decoration of tin plates; but it has occurred to the writer that every town does not present the same facilities for search as the one in which the writer is at present residing; he, therefore, gives an extract from the complete specifications, Nos. 13738 and 14321, 1887 (No. 14321 was completed 1st February, 1888), of a Mr. Rees, "for decorating or printing tin plates and other sheets," as follows:—"The object of my invention is to produce a simple and very efficient means for, and method of, decorating or printing on tin plates and other sheets, which shall have many excellences over the usual methods, especially in the results obtained and in the speed and economy of material and labour with which the operation is effected. In the ordinary methods of decorating and printing on tin plates and other sheets, as at the present system usually employed, the following evils are generally experienced: In the direct system the two hard surfaces of the tin plate or sheet and the stone or other printing block are brought into direct contact, whereby one or the other is very quickly damaged, and therefore, although this is the speediest method, the expense caused by this injury is so great that the most common method is the transfer system. In the transfer system, on the other hand, the impression is oftentimes spoilt by the necessary subsequent operation of removing the paper or other transferring material, which also is wasted after being once used, and fresh paper or material has to be prepared for each impression, whereby also increased expense is incurred; and when this system is employed, the tin plate or sheet has to be coated with a film of transfer varnish, by which the lustre of the tin plate is diminished. By this invention these and other evils are obviated and removed, and the operation is, or may be, effected as quickly as by the direct system, without injury to the tin plate or sheet and the stone or block, while the increased labour and expense of the transfer system are saved, the results are improved, and there is no danger that the impression will afterwards be spoilt in the manner as aforesaid. To carry out this object, and to perform my invention, I take a piece of millboard, cardboard, or other similar material, preferably a hard-rolled and glazed millboard, or it may be a metal or wooden plate, of the required size and shape for the tin plate that is to be decorated or printed; and when made of millboard or other material that requires treatment to render it waterproof, I rub the same with hydrocarbon oil, which, if required, may hold in solution paraffin wax or other similar substance; and on the board or plate before mentioned I secure a piece of varnished cloth or canvas, or vellum, or parchment, or skin, or other material having an impervious surface, preferably leather cloth or oil haize, which covers the board or plate either wholly or in part, in accordance with the design, pattern, or lettering to be printed, and the surface of this material is then, in any convenient manner, made perfectly smooth and level, and is treated with hydrocarbon oil or turpentine, or a mixture of the same, in such wise that a thin film covers the entire surface of the material, or so much of the same as will receive the design or pattern or lettering, the surplus oil or turpentine or mixture, if any, being removed. The required design, pattern, or lettering is created in the usual manner upon a stone or metal plate, or on a wood block or other ordinary material, and is inked over as is customary, and the aforesaid prepared surface of the board or plate is pressed thereon in any usual manner, taking off the impression. The so-treated surface of the board or plate is then similarly pressed on the surface of the tin plate or other sheet that is to be decorated, and the design, pattern, or lettering is properly imprinted thereon, being taken off the prepared surface of the board or plate, which is then lightly rubbed over with fresh hydrocarbon oil or turpentine or a mixture of both to ensure that the aforesaid film is duly in position, and is ready to take another impression from the stone or other printing block, which, if required, has again to be inked, and to transfer this impression in the same manner to the same or to another tin plate or other sheet. To save time and labour and expense in thus decorating or printing on the tin plates or other sheets, I preferably form the prepared surface as before described on both sides of the board or plate, and when one of these surfaces has been pressed as aforesaid, and the stone or other printing block having (if required) been again inked, the other prepared surface of the board or plate is pressed thereto, and the tin plate or other sheet is placed on the treated surface of the board or plate, and on pressure being applied in any usual manner the tin plate is properly decorated or printed or lettered as before described, while at the same time the other prepared surface of the board or plate receives the impression from the stone or other printing block. The tin plate or other sheet is then removed; this so-exposed prepared surface of the board or plate is treated as before described with fresh hydrocarbon oil, or turpentine, or a mixture of the same, and the board or plate is again reversed in position on the stone or other printing block, and the aforesaid procedure is repeated, and so on. In the same manner two or more colours can be worked into the same design or pattern or lettering, in, and by, the usual course of procedure, care, of course, being taken that the several parts are always placed in the same positions in respect of each other by using any of the ordinary registering appliances. It is obvious that this invention can be used and performed as before described, in any of the usual machines, such, for example, as the ordinary hand-working lithographic press, or the ordinary lithographic machine with cylinders or rollers, or otherwise."—N. M.

**Sundial.**—TIMA asks for a method of calculating the various angles of the hour lines with the meridian line for a sundial lat. N. 53° 36'. Also whether the same angles are gone over in each hour in all seasons. I will answer the last question first. There are but four days in the year when the sun casts its shadow correct with a good clock. The sun as a timekeeper is exceedingly irregular, though its irregularities are absolutely regular. This arises from the fact that the earth's equator is not coincident with the plane of its orbit round the sun. Any almanac will give clock fast or slow with the sun to show correct time. Suppose the almanac shows clock fast 15', then when the shadow of the style falls, say, on the four o'clock line, the true time is 4.15, and so on. First of all, we must make our gnomon. The elevation of the

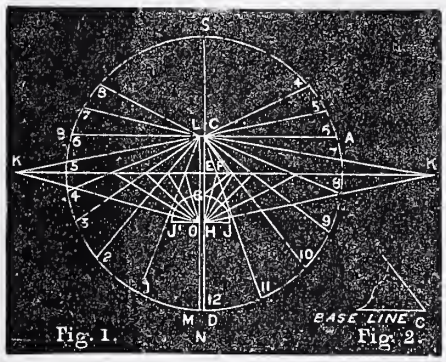

Fig. 1. Fig. 2.

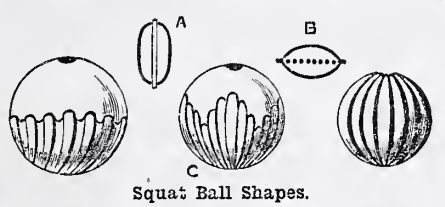
Sundial.

gnomon must be of the same angle as the latitude of the place for which it is intended—that is to say, the edge which casts the shadow must be coincident with the polar axis of the earth. To mark off the angles, draw a straight line, C D; perpendicular to this draw A B. Draw an angle, E C F, equal to the latitude of the place, 53° 36'. Cut this angle by the line K K—the precise position is of no consequence—and make the same angle, E F G. Measure the distance from E to F, and mark off the same from G to H. Place the point of the compass at H, and strike a quadrant from G to J. Divide the distance from G to J into six equal parts. From the point H draw lines cutting those divisions on to the line K K. Now from the point C draw lines to cut through K, intersecting the lines previously made. Line A is six o'clock, K is seven, and so on to eleven, the line C D being noon. Measure the exact thickness of the gnomon, and equal to that draw the line L M, and from that lines corresponding to those already made must be drawn. Carry the lines seven and eight a.m. through the centre, and we shall have our seven and eight hours p.m., and carry the five and four p.m. lines through the centre, and we shall get the five and four a.m. lines. The point of the gnomon, C, Fig. 2, must be placed at C on the lines L and C. If TIMA does not know how to find the angle of the gnomon, or the true meridian of the place where he intends his dial to be fixed, I shall be happy to give him the needed information.—O. B.

**Squat Ball Making.**—NO NAME.—I am sorry your inquiry respecting mill, etc., was delayed. The weight of the mill is 150 lbs., and 20 in. in diameter. I would have sent working drawing, but as the mill is the only one in use, as far as I am aware, it will become the subject of a patent. The delay has been caused by my desire to find a manufacturer of fancy balls in Birmingham, as I understood they were made there; but I have not found one. In Sheffield, Messrs. Tucker and Sons, York Street; Messrs. W. Gallimore and Co., and Messrs. J. J. Maxfields, Arundell Street; Messrs. Pearson and Co., and Messrs. Oates and Co., Rockingham Street,



Squat Ball Shapes.

are agents for them. The fancy balls are made almost round, and then put into a hydraulic press, under dies which, having the flutes or ornamental parts cut in them, are forced into the balls to form the ornaments as shown at C. The squat balls and balls with flanges are made the same way as round ones. To make this shape, edges are not trimmed off, but pressed in two halves and soldered, as at A. These edges are used for turning a bead on the ball as shown at B. The balls are manufactured chiefly in France and the United States of America. The cost of the machines varies from £100 to £300: they are made by Messrs. Bliss & Co., Brooklyn, New York.—B. W. R.

**Marbling.**—HAMMER-CHEWER.—If you can afford about a couple of guineas for six good hand-painted specimens, write Mr. W. G. Sutherland, 15, St. Ann Street, Manchester, and mention WORK as your source of advice.—LONDON DECORATOR.

**Patterns for Turning.**—A. H. J. (*Norwich*).—Mr. Fritz Collins, Summerhays Place, Bath, did supply, and probably still supplies, sheets of patterns for this purpose; but I cannot, of course, say whether they would be such as would suit your taste.—M. M.

**Hot-air Engine.**—J. R. (*Liverpool*).—It would probably take too much room to give directions for making a hot-air engine in the "Shop" columns, but you can get information on the subject in Nos. 1,154, 1,156, 1,088, of the *English Mechanic*. The first contains a drawing by Mr. Seal, which was followed, but failed to work well owing, I think, to the air displaced being too small in comparison with the working cylinder; I think the displacer should move through three or four times the cubic inches that the working piston does. The last number, 1,088, contains a section of Robinson's hot-air engine.—F. A. M.

**Wimshurst Machine.** — W. A. (*Bury St. Edmunds*).—(1) Thin sheet brass will serve equally as well as, if not better than, tinfoil for the sectors of a Wimshurst machine. They need not be lacquered. (2) The brass wire used in making scratch-brushes would be much too rough for the collector brushes, and would, as you say, scratch the sectors and render them useless. The best material for brushes is "yellow warp twist," sold by lacemen at about 8s. or 9s. per lb. This is made of fine electro-brassed copper wire, flattened to form a ribbon, and twisted around a thread of cotton, then several of these threads are twisted together to form a loose cord. A small bunch of these cords forms an excellent brush for a Wimshurst machine. If you experience any difficulty in getting this material, write to Messrs. Bonney & Co., 19, Avenue Road, Lewisham, S.E. They are connected with the trade, and will get you the twist at a reasonable cost.—G. E. B.

**Polishing Bullocks' Horns.**—J. M. (*Sutton-on-Hull*).—If they are at all rough, the roughness must be got rid of by rubbing with rather fine glass-paper, and then by scraping with a sharp steel tool, such as a razor, or else with a piece of glass. The actual polishing is done after this by some cutting powder—such as Trent sand and water or powdered pumice and water—applied by means of cloths, until quite a smooth, regular surface is obtained. After removing all particles of this coarse powder, we next try a finer one, such as powdered charcoal or very fine brickdust; both of these with water, and on some pad or bob made of cloth, to allow of a great amount of friction being used with them. To finish and obtain a bright surface, the horns should be washed quite clean; and then washed chalk or very fine whiting can be applied, as before, on a cloth pad. This can be moistened advantageously with some very weak acid—vinegar will do—and a final finish can be given with some dry whiting applied by the palm of the hand. It is not the materials so much as the friction that is essential in obtaining a good polish.—H. S. G.

**Combined Knife and Spoon.**—J. H. (*Uxbridge*).—We cannot advertise your article in WORK free of cost. You must be prepared to pay for gaining publicity for your invention. If it is a good thing you would do well to consider the patenting of it.

**Kaleidoscope.**—R. W. I. L. (*Gawler, South Australia*).—I have forwarded a second letter (registered) to your address, seeing that the first had failed to reach you.—T. R.

**Sauce.**—ONE IN A FIX.—Questions concerning sauces, pickles, or condiments, do not come within the scope of WORK. You cannot do better than refer your question to the Editor of *Cassell's Saturday Journal*.

**Applied Mechanics.**—R. R. (*Dumbarton*).—You cannot do better than purchase "Applied Mechanics," by Sir R. S. Ball (Cassell & Co., London, E.C.), price 2s.

**Ebony Stain.**—A. C. (*Leicester*).—Your query has been fully answered since your letter was written, under "Ebony Stain," in "Shop," p. 332, No. 125, which please read.—LIFEBOAT.

**French Polish.**—T. F. (*Willington on-Tyne*).—As regards your sideboard, we can only surmise that you wished to stain it in imitation of walnut; or why use vandyke brown? for in getting it nearly black you must have been very lavish in its use. A too lavish use of stains generally gives to the articles thus treated a painted rather than a stained appearance. It is always best, in staining, to build up the colour gradually. Two coats of weak stain will be found far better than one strong coat; and it is always better to try their effects on odd pieces of wood previous to using on the finished article. Had this precaution been taken, it would have saved you much trouble, for we regret to say it will *not* be possible to make your sideboard lighter coloured without removing the varnish. Which kind you used, by the way, you did not tell

us. For hints "How to remove French polish or varnish," please refer to "Shop," p. 188, No. 116. If, however, you decide to make the best of a bad job, the varnish can be French polished on if the precantion be taken to make it smooth with fine glass-paper, taking care not to rub the stain off the sharp edges when working on the carvings and mouldings. If, when "bodying up," you still find the colour hold out dark, you may give to the whole a richer appearance by using red polish, made by adding a few drops of red stain—which is made by dissolving two-pennyworth of bismarck brown in a quarter of a pint of methylated spirits. Your sideboard, if made true to the design, would look remarkably well thus finished. It may be that you have been misled by these so-called browns. Bismarck brown gives a rich red colour, while, as yon know, vandyke varies from brown to nearly black. We hope these hints will be of use to you, and help you out of your difficulty. If not, write again.—LIFEBOAT.

**Tools.**—GRANITE.—Both S. J. Addis and J. B. Addis & Sons are known as makers of *first-rate* carvers' tools. Unless GRANITE wishes to buy in large quantities, it will be better to get the tools through the nearest tool dealer, any of whom will supply Addis's tools. Nurse & Co., who advertise in WORK, pnblish a catalogue which contains a list of carving tools, tabulated as Addis's tools are numbered. Melhuish also does the same. As to the other maker, GRANITE will perceive that these answers should be so framed as to benefit other readers as well as the querist, and should not depreciate any tool maker in comparison with others. That being so, I can only say that I have not chanced to try any gouges by Greaves, but that I have had chisels and plane irons by that maker, and that they have been of excellent quality.—B. A. B.

**Organ Pipes.**—E. A. P. (*Beckenham*).—It has already been pointed out (col. 1, p. 382, No. 128) that the statement that the 16 ft. tone can be obtained from a 4 ft. pipe is a slip. You can reduce the height of your organ in several ways: (1) by planting some of the largest pipes on the floor; (2) by

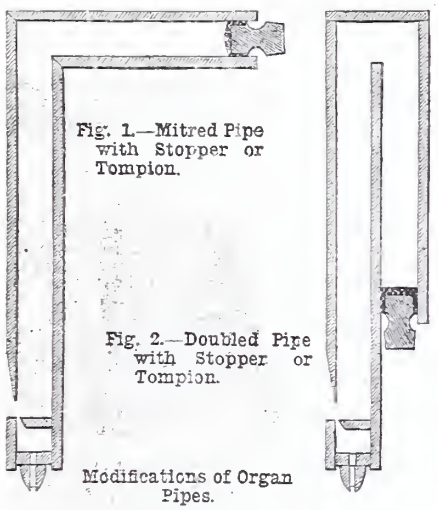


Fig. 1.—Mitred Pipe with Stopper or Tompion.

Fig. 2.—Doubled Pipe with Stopper or Tompion.

Modifications of Organ Pipes.

laying them horizontally at the back of the instrument; (3) by mitreing some of the largest pipes; or (4) by doubling them. I annex a sketch showing the last two items. So long as you obtain the length and diameters of the pipe, it does not matter whether the pipe is straight or not. Indeed, bonrdon pipes are often improved by being mitred. Both open and stopped pipes can be treated in these ways for the purpose of redncing their height.—M. W.

**Machines for Blowing Organs.**—J. A. G. (*Southport*).—There are motors made to work by electricity, and others by gas; bnt I am unable to state the initial cost or the cost per hour of working. Inqnire of the small engine makers in the London Directory.—M. W.

**Bicycle Chains.**—H. H. C. (*Yeovil*).—I am not aware of any chain being made small enough for a model tricycle. Information on the subject can be had of the following firms (chain makers): Brown Bros., 7, Great Eastern Street, London, E.C.; Perry and Co., Limited, Birmingham; F. Brampton & Co., Oliver Street, Birmingham. If H. H. C. can make a model tricycle, it should not be difficult to make the chain any size he wants. He has only to make a punch in the shape of each link, to cut the links from a bit of sheet brass, then get a bit of very fine brass tube, say, ⅛ in. out, and cut in lengths for the rollers.—A. S. P.

**Safety Bicycle.**—CYCLE.—(1) Messrs. Cassell and Co. will snpply back numbers of WORK, containing cycle-building papers, four of which are now pnblished. (2) W.S. tubes in large quantities from Herbert & Hubbard, Coventry, and Credenday (tube makers), Birmingham. Tubes, small quantity cut to length, of St. George's Cycle Co., Upper Street, Islington, London; Brown Brothers, 7, Great Eastern Street; and others. (3) The best enamel I know of to pnt on with a brush without stoving is the club black, hard-drying enamel, sold in all cycle shops in 1s. bottles; got in large quantity of the Silver Enamel Co., 97, Hampstead Road, London.—A. S. P.

**Boiler Feed.**—INNEK.—In place of a force pump an overhead boiler feed may be used, but the tank must be at a sufficient height to resist the pressure of steam, which would otherwise drive the water out of the boiler up into the tank. To find the necessary height of tank in feet above the boiler, multiply the gauge pressure of steam in pounds per square inch by 2¾. Thus, if you have fifteen pounds pressure in the boiler, the feed tank must be 15 × 2¾ = 35 ft. above it. You may, instead, feed your boiler by a small injector. These are now sold by model makers.—F. C.

III.—QUESTIONS SUBMITTED TO CORRESPONDENTS.

**Stick Handles.**—APPRENTICE writes:—"Will anyone give me information on the mixture of imitation silver for making stick handles? the cost of same, etc., being a consideration."

**Black Varnish.**—T. L. (*Chew Magna*) writes:—"Will any reader of WORK kindly inform CARADOC the ingredients used, and their proper quantities, for making black varnish suitable for ironwork, etc.?"

**Inlaid Oval Table Top.**—A. E. (*Wandsworth*) writes:—"I have a mahogany table (round) diameter 2 ft. 9 in. I want to make a movable *deal oval shape top* for same, and would be glad of any advice in 'Shop,' particularly about the thickness of wood, how to find dimensions, joining, fixing the top easily and firmly, also what the exact length of the oval would be if the narrowest part is 3 ft. 6 in. Would one of the exhibitors of inlaid tables at the recent WORK Exhibition kindly give me instructions how to inlay the table top? Every time I visited the Exhibition I spent some time in admiring and examining the work both of prize and non-prize winners, but failed to find out how the wood was cnt so even, and fixed in so true. I should also be glad of a list of suitable woods, thickness, and the best place to obtain them. Should I begin to inlay work in the centre or outside? A design would be acceptable."

**Metal Plate Book.**—SHEET IRON writes:—"In No. 58 of WORK, page 94, ALIQUANDO mentions a book on metal plate work, by C. T. Millis; would he kindly give price and where pnblished?"

**Bamboo Work.**—E. C. W. (*London, E.C.*) writes:—"I should like to be informed where I could obtain small quantities of lacquered panels for bamboo work; also buttons for the ends of cane. I should also like to know whether there is a book published on bamboo work."

IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Lubricating Oil.**—PETER writes, in reply to F. F. M. (*Edinburgh*):—"The following is a recipe for lubricating oil for bicycles. Use one-fourth of paraffin oil to neatsfoot oil. It will work all right. Just shake up before oiling machine. I use it for my own machine."

**Mandrel for Lathes.**—H. F. (*Stratford, E.*) writes:—"I do not know what size mandrel J. T. (*Walworth*) (see page 159, Vol. II.) requires, but I snppose it is not larger than one I had made some time ago, for a 4 in. heavy metal-turning lathe, and it only cost me 15s., and was hardened cast steel. I can recommend the firm as being very moderate in their charges, and workmanship and materials A 1. The address is: Price's Manufactnring Co., 24, Randall's Market, Poplar, E."

**Wood Pulp.**—J. W. G. (*Redhill*) writes, in reply to ÆON (see page 538, Vol. II.):—"There is the Wood Pulp Company, Thetford, who make all kinds of hollow ware of the above kind."

**Punt.**—W. H. M. (*Preston*) writes, in reply to W. P. (*Cardiff*) (see page 634, Vol. II.):—"Does this correspondent require information as to making a dinghey or yacht's punt, or does he refer to a Thames punt? In either case I shall be glad to assist him on hearing further."

**Mining Engineering.**—M. (*Bishop Auckland*) writes, in reply to S. H. M. (*Liverpool*) (see page 334, No. 125):—"You should, about the age of seventeen, be articled to a mining engineer in practice for four years, and at or near the end of the term go in for the examinations which are held in various towns. You will have to pay a preminm, and will not receive any pay during the time you are serving your articles. You can go in for one branch of mining only, but it is better to know all. If you had given more definite particulars, I would have been better able to advise you."

V.—BRIEF ACKNOWLEDGMENTS.

Questions have been received from the following correspondents, and answers only await space in SHOP, npon which there is great pressure:—W. B. (*York*); T. S. (*Liverpool*); J. R. (*York*); G. F. C. 3 STOPS

# THE WONDERFUL ORCHESTRAL ORGANETTE.

3 STOPS

(BY ROYAL LETTERS PATENT.) *Hundreds of Testimonials.*

SPECIAL OFFER from the LARGEST Organette Works IN THE WORLD.

☞ A FOUR GUINEA ORGANETTE FOR 35s. ☜

WE are the sole Proprietors and Makers in the United Kingdom for this new and Wonderful Instrument. Having for many years manufactured and sold enormous quantities of Automatic Reed Organs, Organettes, &c., it has ever been our aim to produce at a Low Price an Organette capable of a **VARIETY OF TONES**, the Organettes heretofore placed before the Public having but a limited compass, and but one range of tone. While we have given universal satisfaction, we still have had as our motto, "Excelsior," and now can exclaim, "Eureka!" because, without increasing the price of the Orchestral Organette (our latest production) over other instruments in the market, we have succeeded in producing the very **ACME OF MUSICAL INVENTION**, an instrument with as much variety of tone as an organ costing £25. The illustration gives you but a faint idea of general make and finish; but every Orchestral Organette is supplied with **28 FULL-SIZED AMERICAN ORGAN REEDS**, the same size and quality as those used in a cabinet organ. The reeds are placed in a novel manner (patented) over a double suction bellows, and are controlled by **THREE STOPS** as follows, viz.: Flute, Expression, and Vox Humana. The music is produced by perforated sheets, which pass around the Organette in endless bands, enabling a tune to be played over and over again without stopping, furnishing the **GRANDEST ORCHESTRAL EFFECTS**, either in sacred, secular, dance, or vocal music, affording a rich, sonorous, and powerful accompaniment to the voice, requiring absolutely no skill in the performer, and **THE RANGE OF MUSIC AND TONE IS PRACTICALLY UNLIMITED**. By the manipulation of the stops, a tone as soft and sweet as a zephyr or a loud, long, and swelling melody may be produced; trills and high falsetto, as well as reverberating bass, and all manner of pleasing combinations at the will of the performer.

By Royal Letters Patent.

A MERE CHILD CAN PLAY IT.

*Size, 14⅝in. long, 13¾ wide, 9½ high, weighs 8lbs.*

**COUPON. 678.**

REGULAR PRICE £4 4s.
REDUCED PRICE £1 15s.
GOOD UNTIL OCT. 1ST, 1891.

*Signed, J. DRAPER.*

Any reader of this Paper who forwards this Coupon before the dates named herewith can receive **ONE** Orchestral Organette at reduced price of **£1 15s.**

We wish to introduce one of these Orchestral Organettes in every town and village in the United Kingdom. We caution you against the many worthless automatic instruments being sold under various names. We alone are the **SOLE PROPRIETORS OF THE ORCHESTRAL ORGANETTE** (ne plus ultra) and you must order direct or through our authorised agents. Remember, the Orchestral Organette is **NOT A TOY**, but a **LARGE** and **POWERFUL INSTRUMENT**, built exactly on the principle of **CHURCH ORGANS**; they are made in the most substantial manner, highly polished and decorated in gold. The reeds are the product of machinery costing thousands of pounds, and are so powerful they produce sufficient volume of music for the drawing-room, chapel, lodge, or ball-room. There is nothing about them to get out of order. They positively improve with age, producing richer and sweeter tones after having been used a few years. For **HOME ENTERTAINMENTS THEY ARE UNSURPASSED.**

Bear in mind that each instrument has **FOURTEEN MORE REEDS** than any other Organette in the world, and they are **ORGAN REEDS**, and the special feature **THREE STOPS**, a characteristic of no instrument except a costly organ. Our regular price for the Orchestral Organette is £4 4s. Having just put it before the public, we will sell a limited number to the readers of this paper at £1 15s., provided the above Coupon is cut out and sent with order not later than the date given in it, and we furthermore agree to **REFUND THE MONEY AND PAY CARRIAGE** to anyone not entirely satisfied after receiving it. By the aid of the Stops, viz., Expression, Flute, and Vox Humana, there is not a piece of music which cannot be played with all the varying effects of an orchestra; a false note is an impossibility, and the most difficult operatic air is played with as much ease as the most simple hymn. In many homes will be found a Grand Piano or Organ, with not an inmate of the household, even the most expert player, who can interest company on either so well as a child of three years old can on the **ORCHESTRAL ORGANETTE**. Remember, any tune can be played with artistic effect by anyone, young or old. You can play **DANCE, SACRED, OR SENTIMENTAL MUSIC** with as much effect as that produced by a **FIRST-CLASS FOUR-PIECE ORCHESTRA.**

Remember, our regular price is £4 4s.; but as we have found a well-pleased customer our best advertising medium, we have decided to sell a limited number, as an introduction to the readers of this paper, at **£1 15s.**, provided the order is received not later than the date printed in the coupon immediately beneath the illustration of the Organette. We will give a selection of **MUSIC FREE**, with each Instrument. Send money and Coupon by Registered Letter, Crossed Cheque, or Money Order to **J. DRAPER, BLACKBURN.** For 2s. extra, the Organette will be sent to any part of the United Kingdom, carriage paid. List of Tunes and Testimonials sent anywhere free. Visitors can inspect the Factory daily from 9 a.m. to 6 p.m. Saturdays close at noon. *N.B. ABOVE TIME EXTENDED TO FOREIGN CUSTOMERS.*

*Address* **J. DRAPER, ORGANETTE WORKS, BLACKBURN. LARGEST ORGANETTE WORKS IN THE WORLD.**

## £500 CHALLENGE!

We will give £500 to anyone who can prove that we ever solicited a testimonial, or that any in our catalogues are not genuine. During October, November, and December, 1890, we received over Five Hundred Testimonials for our Orchestrals. Surely this speaks for itself.

# FRETWORK FOR AMATEURS

OF BOTH SEXES AND ALL AGES

The most Fascinating and Profitable of all Home Pastimes

ARE universally admitted to be worth a Guinea a Box for Bilious and Nervous Disorders, such as Wind and Pain in the Stomach, Sick Headache, Giddiness, Fulness and Swelling after Meals, Dizziness and Drowsiness, Cold Chills, Flushings of Heat, Loss of Appetite, Shortness of Breath, Costiveness, Scurvy and Blotches on the Skin, Disturbed Sleep, Frightful Dreams, and all Nervous and Trembling Sensations, &c. The first dose will give relief in twenty minutes. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

## WORTH A GUINEA A BOX.

For Females of all ages these Pills are invaluable, as a few doses of them carry off all humours, and bring about all that is required. No female should be without them. There is no medicine to be found equal to Beecham's Pills for removing any obstruction or irregularity of the system. If taken according to the directions given with each box, they will soon restore females of all ages to sound and robust health. This has been proved by thousands who have tried them, and found the benefits which are ensured by their use.

For a Weak Stomach, Impaired Digestion, and all Disorders of the Liver, they act like magic, and a few doses will be found to work wonders on the most important organs in the human machine. They strengthen the whole muscular system, restore the long-lost complexion, bring back the keen edge of appetite, and arouse into action with the rosebud of health the whole physical energy of the human frame. These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the Nervous and Debilitated is, BEECHAM'S PILLS *have the largest Sale of any Patent Medicine in the World.*

## Beecham's Magic Cough Pills.

As a Remedy for Coughs in general, Asthma, Bronchial Affections, Hoarseness, Shortness of Breath, Tightness and Oppression of the Chest, Wheezing, &c., these Pills stand unrivalled. They are the best ever offered to the public, and will speedily remove that sense of oppression and difficulty of breathing which nightly deprive the patient of rest. Let any person give BEECHAM'S COUGH PILLS a trial, and the most violent Cough will in a short time be removed.

Prepared only, and sold Wholesale and Retail, by the Proprietor, THOMAS BEECHAM, ST. HELEN'S, LANCASHIRE, in Boxes, 9½d., 1s. 1½d., and 2s. 9d. each.

Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*

### MAKING THE BEST OF A BAD HOUSE.

BY MARK MALLETT.

INTRODUCTORY REMARKS—MY HOUSE AS I FOUND IT—A WHITEWASHED KITCHEN AS A SNUGGERY—MAKING MY STUDY—THE FIREPLACE.

*Introductory Remarks.*—Of that estimable class of persons to which the writer, in common, probably, with many of the readers of WORK, belongs—those, namely, who have more taste and skill than money—the great majority have to live in something very different from what they would picture as "ideal homes." The ordinary dwellings of those who have to work for their bread are, as a rule, unsightly and uninteresting. Effectual shelters from the elements they may be, but in other respects they are mere makeshifts.

Now I wish to show how we, who have taste and ingenuity, may do much to improve matters (so far as our own homes are concerned) without money. We, the readers of WORK, are not helpless beings. We know how to use our hands in many ways, and in various arts and crafts are independent of paid help. From my own experience I propose to give some hints to those who have the will and the ability for this kind of work, but may not see exactly how to set about it.

I propose to describe and illustrate some of the changes that I have myself made in a most unpromising house. I do not suppose that any reader can follow exactly in my steps, ugly houses being of so many different sizes and patterns; but I trust he will find what I have to say suggestive, and that he may be able to adopt and improve upon my plans. Also, that I may be of as much practical use as possible, I hope to point out alternative methods when such seem likely to be of more general service than those adopted by myself.

Before I bring these preliminary remarks to a close, there are certain points to which I should especially wish to call attention. They are, that from first to last I had, for imperative reasons, to carry out my work on the most economical lines; that, with some few trifling exceptions, all that was done was done with my own pair of hands, and

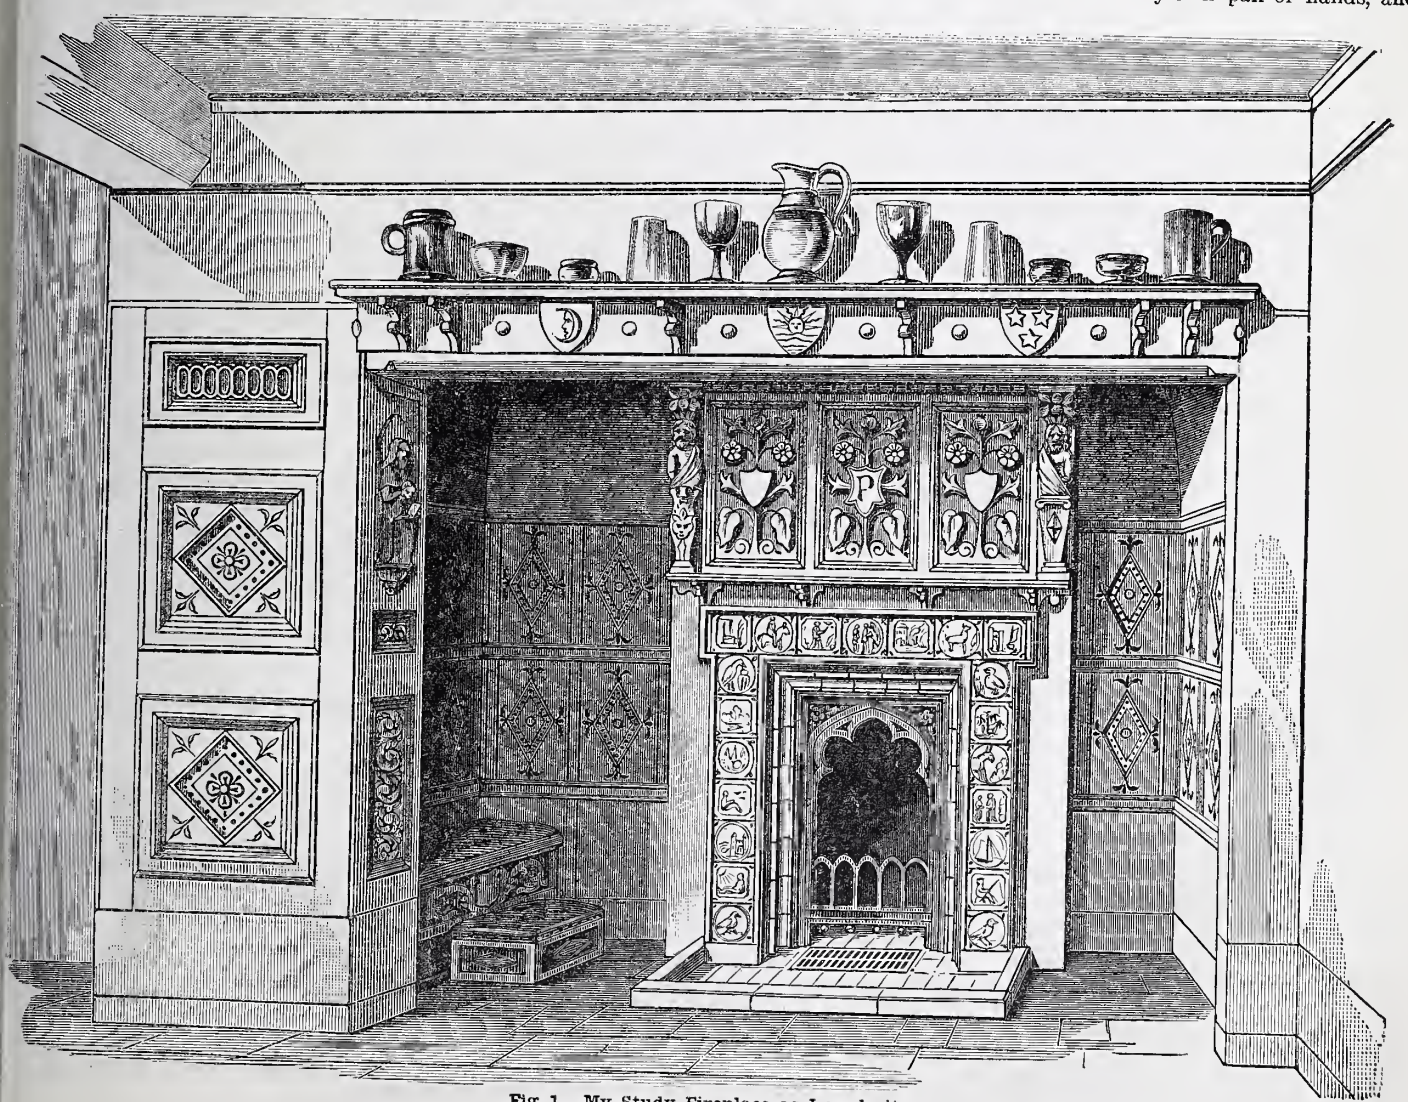

Fig. 1.—My Study Fireplace as I made it.

that what I accomplished was not the amusement of a life of leisure, but the occupation of the evenings and odd times of days spent in that toil for daily bread which falls to the lot of most of us. I particularly mention these things for the encouragement of those fellow-workers who, in respect to the gifts of fortune, may not be better situated than myself.

*My House as I found It.*—That house which has been the scene of my labours, and which came into my hands some few years since, is in a country village, and probably was once a farmhouse. It is an old stone building, with low ceilings, and though the principal windows seem once to have had good stone mullions, these have long since been knocked away to give place to mean wooden frames. When I entered upon it I found the walls, where not whitewashed, covered with cheap and tawdry papers, and the woodwork throughout painted of a uniform and dismal drab. When I mention that its rateable value was estimated at ten guineas *per annum*, I shall enable the reader more clearly to realise what manner of house it was.

I must admit that it was not what would generally be considered an attractive residence. Such of my friends as I carried to see it in its pristine state wondered at my choice, and one or two of the more intimate told me candidly that I should never be able to make anything of it.

But I was not disheartened. I gave my friends to understand that my house had one point in its favour which they had not taken into account—namely, that it was so utterly bad as to have no part on which I should fear to make experiments or fear to spoil, and it was therefore the right sort of subject to take in hand. In short, it was my private belief that there could be no house so hopeless but that its inmate might, by judgment and perseverance, make it a thing of interest and beauty. The reader shall judge whether in the case in hand I was in the right.

*A Whitewashed Kitchen as a Snuggery.*—On the ground floor of my house was one room into which my friends looked with more than the usual amount of despair on their faces: it was that which I had selected for my especial den and sanctum. Its size was 18 ft. by 12 ft. On one side a door led to it from the modest entrance hall, and on the other a second door opened from it to the garden. It was lighted by a single window of no great size at one end. Across the middle of its ceiling ran a heavy wooden beam. The bare, whitewashed walls had neither cornice nor skirting-board. It had a large, open fireplace some 7 ft. wide, which projected three or four feet into the room. It appeared to have been used as some sort of kitchen (though not needed as such, there being a sufficient kitchen elsewhere), for, in place of the old flat hearth, a kitchen range had been introduced. One good feature only could my friends see in this room—it had a really fine old oaken floor.

*Making my Study—the Fireplace.*—It was on the fireplace that I began work. To find a substitute for the kitchen range, I hunted through the old stock of an ironmonger, and for 5s. 6d. bought that grate, of the fashion of forty years since, which appears in Fig. 1. In the days when it was made people had not learned that a room is best warmed by a fire near the floor level, and this grate was intended to be perched six inches higher than met my approval. I therefore caused my mason to bury the lower part beneath the level of the floor. And here I should state that, though I employed a mason to set this grate and the bricks and tiles around it, this was the one and only instance in which any paid workman entered the room.

The reader, as he looks at Fig. 1, may think the arrangement of my grate eccentric. Immediately surrounding it is a course of moulded bricks, which scarcely cost me more than bricks of ordinary shape would have done, but these lead very well to the course of tiles which succeeds them. Mine are old Dutch tiles; I got them from builders who had saved them from the wreckage of ancient houses. Some of them were not thought worth making a charge for, others cost me twopence or threepence each—2s. 6d. in all. But, being genuine old things, they have more interest than costly new Minton tiles could have. As ornaments for the hearth, such tiles, made chiefly at Delft, in Holland, seem to have been introduced to this country about the time of "Dutch William," and they were largely imported during the reign of the first George.

The overhanging of the two end tiles of the top row was a matter of necessity; the alternative lay between that arrangement and cutting a tile in two, but I think it will be admitted that I have so dealt with this difficulty as to make it rather add to the effect than otherwise.

I must also call attention to my fender of stone curbing. This cost me nothing. It is made of waste strips of Portland stone, which I looked out in a mason's yard and had for fetching away. I trimmed off their edges and dowelled and cemented them in place myself. Of the woodwork of my fireplace I must speak in my next paper.

## A WORKSHOP GRINDSTONE.

BY ELECTRON.

MOUNTING CONVENIENT FOR ORDINARY ROOM—FRAME, HOW MADE—AXLE—GRINDSTONE—FIXING GRINDSTONE—CAST-IRON BEARINGS—DRIVING-WHEEL AND AXLE—BEARINGS—CRANK—TREADLE—CONNECTING-ROD—SCREWING DOWN FRAME—LEATHER BELT—TRUING GRINDSTONE.

ANYONE having a workshop in an attic, or other room where it is not convenient to have a grindstone, must have felt the want (especially when working at night) of some means of grinding any special tool. The grindstone about to be described may be set in any room, and will be found very useful. A grindstone is sometimes made to fix between the centres of a lathe for any small work, but it is not always convenient to remove work from the lathe to fix the grindstone; and the wet and dirt from a grindstone are liable to spoil a good lathe.

Fig. 1 is a side view of grindstone, to a scale of 1½ in. to the foot. The frame is of wood, 2 ft. 8 in. high. The rails may be any size: 1½ in. by 1 in. will be suitable. They must be made as shown, mortised, glued, and pinned together. Make two frames, equal in size, and fix them 6 in. apart by four rails, which may also be mortised; also fix under each cross-rail a ⅜ in. bolt, passing through both frames, and screwed up with a nut; this will secure them firmly together. Next prepare an axle for grindstone of wrought iron, 8 in. long. The grindstone should be 3 in. or 4 in. in diameter, and if the hole in it be 1 in. square, the thickest part of axle should be forged 1⅛ in. in diameter. A collar must be formed in the centre, about ½ in. deep and ¼ in. thick. The ends should be forged down to ¾ in. in diameter. Turn the axle and bearings true, making the thickest part to fit the hole in stone. Slightly reduce about 1 in. at the outer end and screw it, and fix a nut and washer. When the grindstone is put on, it can be fixed by screwing up tight with the nut and washer. A piece of hard wood should be fixed at the opposite side of the collar, and turned up to form a driving-pulley for flat belt. Fig. 2 is a section of axle.

Next provide four bearings of cast iron, as shown in Fig. 3. The holes may be cast in them, and reamed out to fit ends of axle. Fix two to top of frames by screws.

Next prepare a driving-wheel and axle. The wheel should be about 18 in. in diameter, with a flat rim for belt. A barrow-wheel will make one. The axle for this

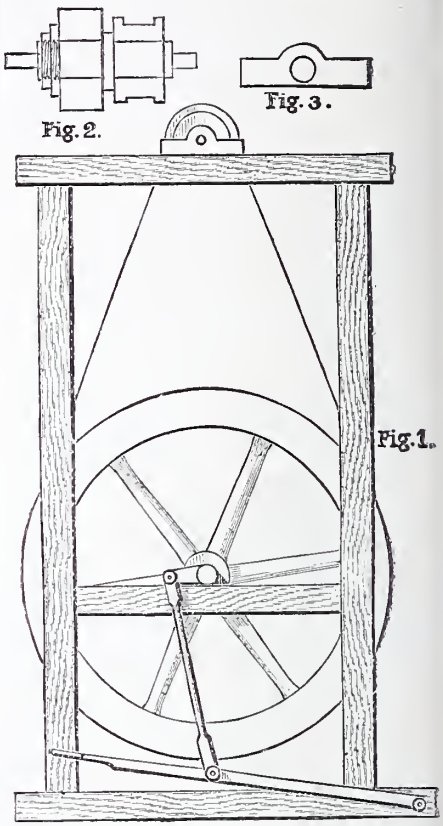

**Fig. 1.—Side Elevation of Grindstone. Fig. 2.—Axle of Grindstone. Fig. 3.—Bearing.**

wheel should be 9 in. long, projecting an inch through one bearing. The wheel may be fixed in the same manner as the stone, or keyed on.

The bearings may be made of hard wood, if preferred, as it will last a long time.

The crank may be of either wrought or cast iron, with not more than 2 in. throw. It must be keyed on the projecting end of axle.

Next prepare a treadle and connecting-rod. The treadle is about 18 in. long, of iron ¾ in. by ¼ in., one end being hammered out for the foot to rest on. It may be fixed to a bolt passing through frames, or to a bearing fixed on the floor.

The connecting-rod has a double end fixed to treadle by a small bolt and pin, and the top end is fixed to crank-pin by a pin and washer. The connecting-rod should be made so that when the crank is at its lowest point the treadle is just clear of the floor, or by using oak or ash the treadle and connecting-rod may be of wood.

When all is fitted up, the frame may be screwed to the floor, and a flat leather belt fixed on driving-wheel and pulley, and the machine is ready for work.

If the edge of grindstone does not run true, it must be trued by using the end of an old file as a turning tool. A rest may also be fixed on the top of framing to rest the tools on while being ground. Anyone making this machine will find it very useful, and the cost need not be much.

## ARTISTIC LITHOGRAPHY.

BY MISS ADA J. ABRAHAM.

### Practical Work: Colour.

Number of Printings — Tracing — Tallies — Register Marks — Gripper — Numbering Tallies—First Tracing from Printers—Order of Printing Colours, etc.—Strength of Colour—Mixtures of Colours—Yellow —Blue—Pink—Brown — Greys — Roughing —Production of Texture.

The first thing to be decided on is the fewest number of printings in which it is possible to reproduce the sketch, which is done by looking carefully over it and finding out which colour it is possible to do without, by mixing two or more of the other colours together to get the desired shade, when the remaining colours will be the fewest number in which the sketch can be reproduced.

Commence by making a careful tracing of the sketch on diaphanie paper in lithographic ink, and as this paper contracts and expands it should not be lifted uutil the whole tracing is finished; all the corners should be gummed to the sketch, and if necessary a piece of white paper can be slipped between to see the effect of the tracing. Draw the outline, and mark any different colours it may contain in very clear, steady lines, making the lines of the outline rather thicker than the others, so that the different objects can be easily distinguished, then every variety of colour and difference in light and shade should be drawn in dotted lines. Six little squares, technically termed "tallies," should be drawn at the side of the drawing, and three little crosses made at the top and bottom, to use as register marks. One would be sufficient, but it is usual to do three or even more. Fig. 34 is a facsimile of how the tracing of a humming bird and leaves should look when finished; and as it is impossible in Work to give coloured drawings, I must ask the reader to accept as illustrations the few following diagrams, being the black impressions of the different colours which were worked from an original water-colour drawing.

The crosses or register marks enable the printer in proving to fit the different colours exactly one over the other, and they should be ruled in lithographic ink on each stone. The colours are registered by means of pins; for instance, in the gold stone, that being the first, the impression is taken, when of course the crosses will print at the same time; then for the next colour, say the yellow, the printer takes two pins, pricks a hole in the centre of the two middle crosses, and makes a slight hole in the duplicate ones on the stone. He then, holding the paper in his hand face downwards with the pins, places them in the holes on the stone, thus pinning the paper to it, then removing the pins, the paper is left flat in position on the stone, and the proof pulled. Thus, if blue were printed over yellow, a green cross should be the result; and so on with each colour.

In machine printing the register marks are done away with, as the gripper (a piece of metal that catches hold of and places the sheet of paper in the right position on the stone) answers the same purpose; therefore in placing a drawing on the stone that is intended to be printed in the machine, about ½ in. on one side should always be allowed for the gripper. This edge of the stone is bevelled, and cannot be worked upon. Supposing a sketch, A B C D, were required to be drawn on a stone, E F G H, it should be placed in the position indicated in Fig. 35, E F being the gripper edge.

The tallies should be numbered, and on the first stone No. 1 must be ruled up and filled in solid, with the name of the colour written underneath, the reverse way, and the same done with each of the other colours on the different stones, using a separate square for each colour, so that when the drawing is being proved, the artist can tell the exact shade that has been used, and so have it altered, either lighter or darker, warmer or colder, as the case may require it; and when a correct finished proof is obtained, the printer can be told to follow the exact colour of the tallies for the machine impressions, as the drawings are proved by hand which the artist superintends, and printed by machinery.

The drawings in the next page are worked in chalk, but the same rules should be

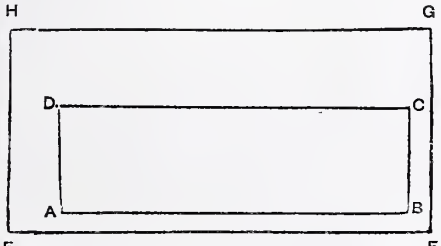

Fig. 35.—Correct Position of Work on Stone.

followed were they done in stipple, and if a great number were required it would be necessary, to enable them to be transferred to a large stone, and perhaps a dozen or even more printed at the same time. After the tracing is made it should be sent to the printers without delay, as it does not keep longer than a few days, and therefore, unless transferred to stone at once, will not go down.

Having received the stones with the red tracings on from the printer, the register marks and tallies should be ruled in first in case they might be forgotten, and the name of the colour to be worked written on the stone so as to read legibly in ordinary writing ink, besides that underneath the tally, in order that the printer can easily distinguish which stone is meant for the colour he desires to print. This writing being in ordinary ink will not print, but will mark the stone, and thus can be always read.

In any drawings containing gold, silver, or bronzes, these colours should invariably be printed first, as they are what are termed "dusting colours"—that is, printed in an adhesive ink, and the powder colour dusted over it; and as this powder flies about, if printed afterwards it would perhaps stick to the other colours in places where it was not required.

In drawings which contain no dusting colours, the yellow should be the first colour worked and printed, as it is a body colour. It does not require such finished work as some of the other colours, although the right strength as to light and shade should be drawn on the stone, and it should be worked with an open texture, being a colour that is likely to clog up in printing.

To work this or any other colour, make a pattern of the colour intended to be printed in water colour, and pick out every part of the original sketch that contains that colour as strong as, or stronger than, the pattern. Those parts should be put in solid on the stone, and any places with the same colour that are in the slightest degree lighter must be tinted accordingly—a very strong tint if it be only a shade lighter, and a light tint if in the sketch the same colour is very much lighter than the pattern.

A good way to judge the necessary strength the colour to be printed should be, and also the strength to work the different tints on the stone, is to take that part of the drawing that is the nearest approach to the pure colour and match it as nearly as possible for the pattern to work from; then take two pieces of white paper, and cut a hole in the centre of each; then by holding one over the sketch excluding the surrounding colours, and one over the pattern, it will be easily seen whether solid or tinting is required to be drawn. In this way a great variety of shades can be obtained from the one colour. The student must remember that wherever the least shade of that colour appears in the original sketch, a corresponding tint of the necessary strength must be made on the stone, for it cannot be put in afterwards unless an extra colour be used; and here the artist's knowledge of colour should assist him in judging what colours mixed together in certain proportions produce the necessary and desired effect.

Everyone knows that yellow and blue mixed together produce green, and therefore a green colour need not necessarily be used in a chromo, but can be obtained by printing blue over yellow. In the same way purple can be produced by printing blue over red, or *vice versâ*, orange by red over yellow, etc. etc., but it must be brought before the student's notice that blue printed over red produces a purple colder in tone than if the red were printed over the blue, and the same applies equally to any other mixture of colours.

Fig. 36 is an impression taken from the yellow stone, and it must be remembered that it would appear much darker on the white paper than in the finished sketch; this is because it is the only colour, whilst in the finished proof it is thrown back, and a good deal covered by the darker ones.

Although two separate printings were required for the gold and yellow, still only one impression of the two colours is here shown, as they do not interfere with each other. The diagram is also a good specimen for showing the result of two colours not being registered correctly.

After the stone is finished it is required to be etched, as previously stated, an impression taken, and all mistakes rectified before any further proofs are pulled.

The blue (Fig. 37) could be worked next, and requires a little finer and better work than the yellow, especially if, as in the present instance, only one blue is used. These two colours will give all the blue, yellow, and green tones necessary to the picture.

The pink (Fig. 38) also requires a nice piece of work, unless the subject was such that one or two reds were going to be used, in which case reserve the good work for them, only putting the necessary quantity as regards light and shade in the first pink.

This colour used with judgment, coming on the top of the blue, gives an excellent grey. We now find that from these three colours a great many varieties are obtained, such as a pale purple, orange, light greys, in different tones, light browns, etc.; and at this stage of the work it is advisable that the artist should have a proof, as far as it has gone, before him, as well as the sketch, and, by continually comparing one with the other, so judge the necessary quantity of work to put in the remaining colours. He may find that in some parts the pink and blue will give a grey dark enough without any additional work, therefore when the grey stone is worked no tinting will be r quired in those places.

The brown stone (Fig. 39) gene ally does the drawing, and i therefore, a very importa colour. It generally requires slightly different treatment i working to the other colour and should be done as early i the work as possible, especially i large subjects, so as to give for to the picture.

The greys should be worke last, and will, therefore, to down all the bright colours, bri the whole drawing into harmon and generally finish it (see Figs. 4 and 41). The light greys nee not be worked as carefully the darker ones, only the to and not the work showing. Th

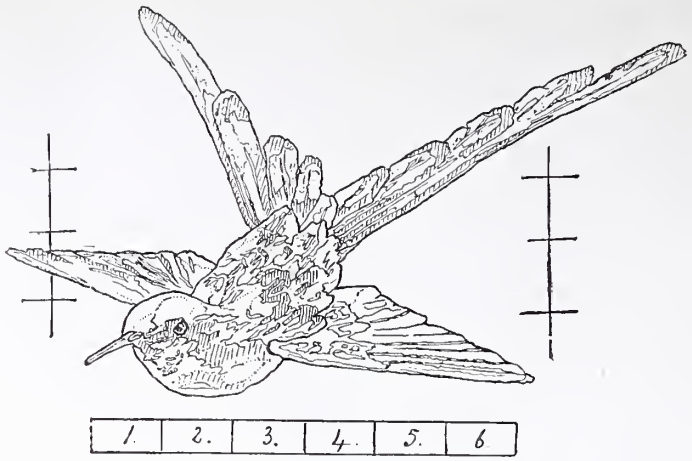

Fig. 34.—Tracing of a Humming Bird.

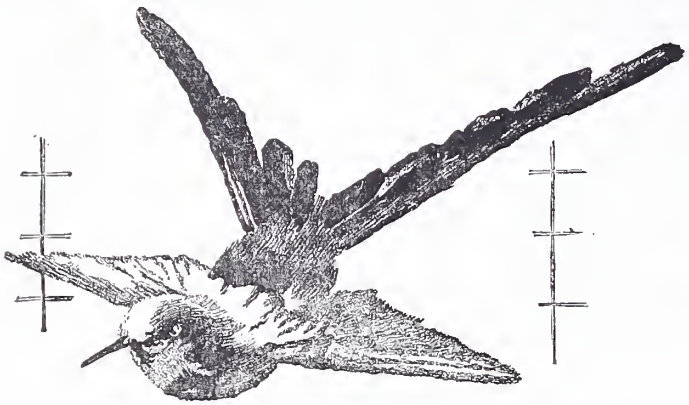

Fig. 36.—Black Impression from Yellow Stone.

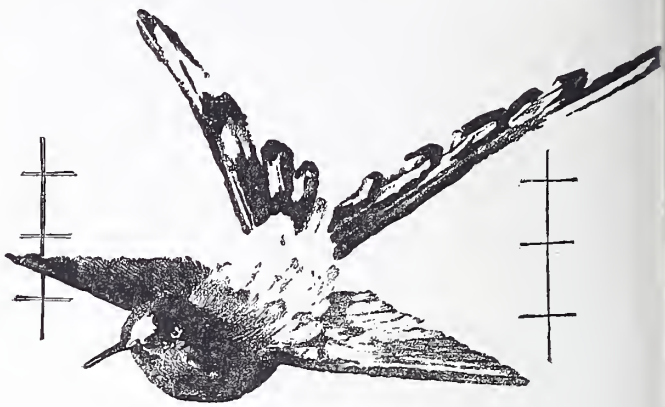

Fig. 37.—Black Impression from Blue Ston

Fig. 38.—Black Impression from Red Stone.

Fig. 39.—Black Impression from Brown Stone.

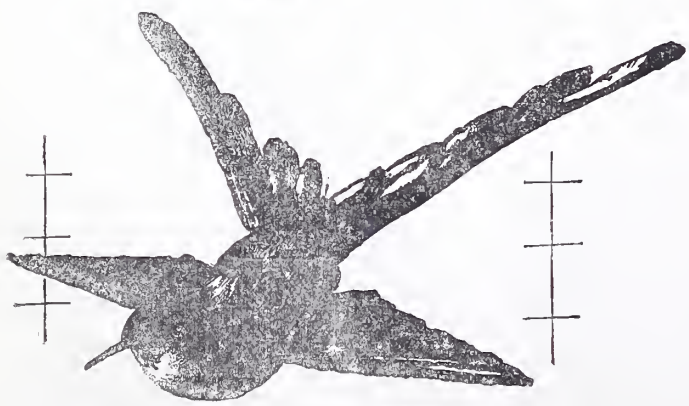

Fig. 40.—Black Impression from First Grey Stone.

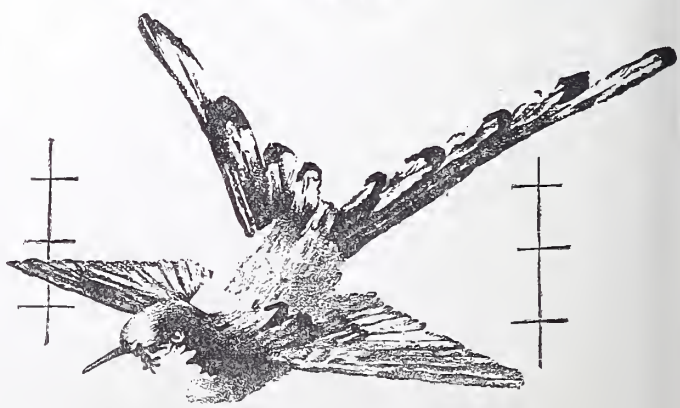

Fig. 41.—Black Impression from Second Grey Stone.

applies equally well to the blues, reds, etc., but the student will soon find out on which stones the best workmanship should be put, and on which to spend the most time. Although it is necessary to do the work as quickly as possible, especially in the light colours, still, it should never be scrambled.

After the picture is entirely finished, it is sometimes roughed—that is, an artificial surface is given to it in imitation of water-colour paper, canvas, etc. This is done in the printing department by inking a grained stone, and then etching it with strong acid. The coarser the texture is required the more the stone should be etched, this being sometimes done as many as three or even four times. Another way is to ink a stone and take an impression upon it from the sheet of paper, canvas, etc., which it is intended to imitate, and which must have been first prepared with gum; then etch the stone in the ordinary way, only stronger, and if the chromo be damped, laid on the stone, and pulled through the machine, it will come out marked as required. In this way any kinds of texture can be copied. The marks of the brush in an oil painting can be imitated in the same manner, by gumming a stone in those parts where they appear, then etching it according to the depth required, and pulling an impression.

There are a great many subjects appertaining to lithographic work which it is simply impossible to touch upon in these papers, such as varnished chromos, photo-lithographs, transfers, and many others; but the above hints on the general principles of the art of lithography in reference to drawing on stone I trust will be of assistance to the student of this very interesting and useful art, and perhaps in some future work I may (subject to the approval and leniency of my readers) enter deeper into the subject of lithographic drawing.

## A USEFUL METAL LATHE.

BY SELF-HELPER.

Introduction—Style of Lathe Castings—Headstock Pattern—Pulley Pattern—The Bed—Poppet Pattern—Hand-wheel Pattern—Holding-down Plates—Fly-nuts.

I was permitted in former numbers of Work to describe two lathes which were of rather simple and makeshift character. One was the primitive dead-centre lathe which might be made by almost anybody who could handle tools, while the other was more elaborate, but still formed principally of wood. Judging from the number of queries which I have received relative to them, I believe that a paper describing how to make an iron lathe will be acceptable to numerous readers of this Magazine. Iron possesses many advantages over wood as a material for lathe-making, the principal being that it is uninfluenced by the weather. We need never fear that the mandril of an iron lathe will stick through the swelling of the headstock by damp. An iron lathe is also lighter-looking and much more graceful than one made of wood, which must ordinarily be rather ponderous-looking and unsightly.

In this paper I will endeavour to write for those who know very little about engineering and carpentry, and if I appear too simple to some, I will ask them to consider that there are other readers of Work who are not as clever as they, and who must be catered for.

At the very outset two questions suggest themselves to us—namely, what size shall the lathe be, and where shall I get castings? There are, I think, two classes of lathe users. The first, who want only a table lathe, would embrace boys and those who require the machine for the production of very small pieces of turnery, such as are used to decorate fretwork and small articles of joinery. For this class, a lathe whose centres are two inches and a half or three inches from the bed would be suitable; and such a lathe might be easily carried in a large box and mounted on the lid when in use.

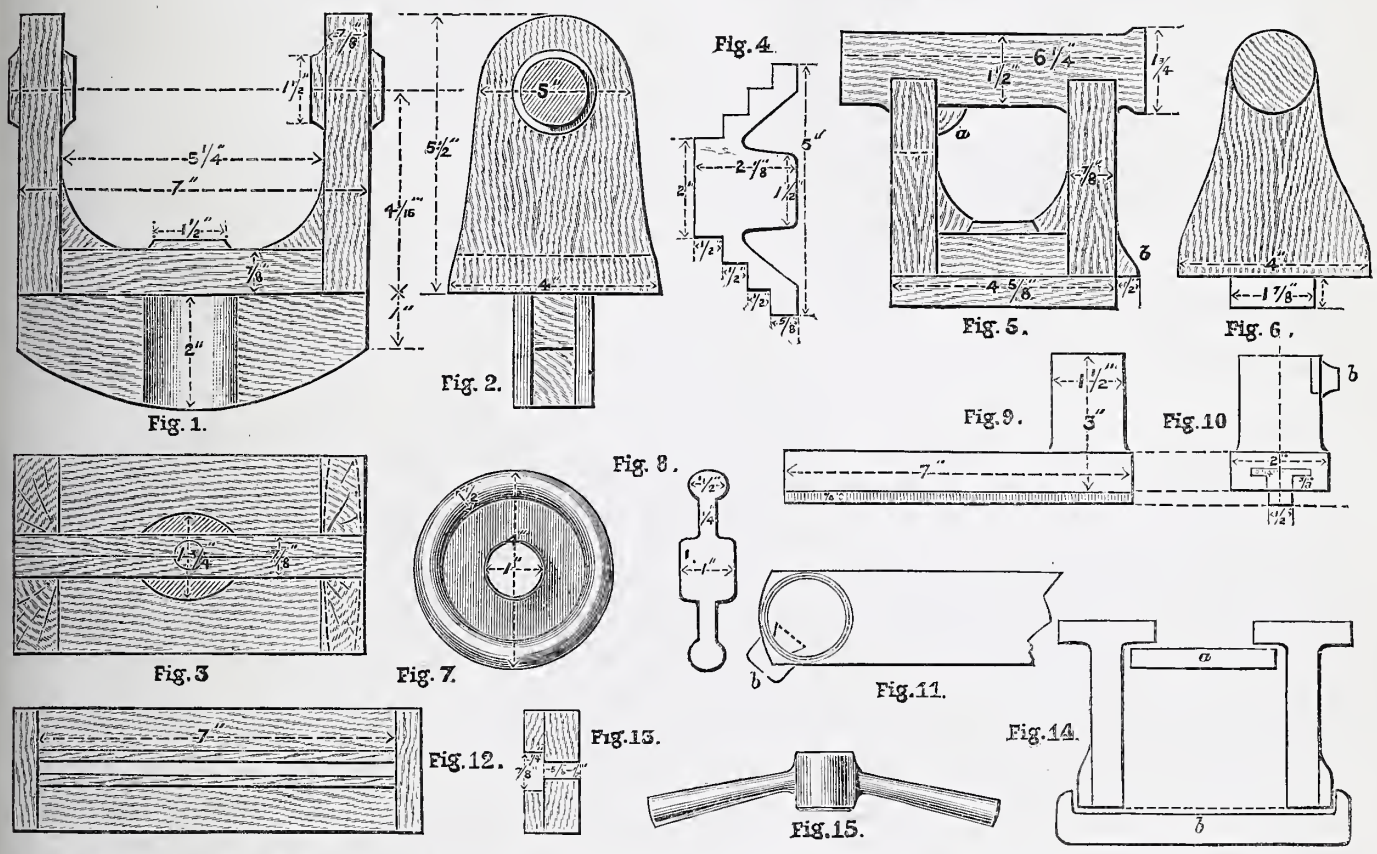

Fig. 1.—Headstock Pattern (Side View). Fig. 2.—Ditto (End View). Fig. 3.—Ditto, as seen from below. Fig. 4.—Sectional View of Pulley Pattern. Fig. 5.—Poppet Pattern (Side View). Fig. 6.—Ditto (End View). Fig. 7.—Hand-wheel Pattern (Side View). Fig. 8.—Ditto (Sectional View). Fig. 9.—Hand-rest Socket (Side View). Fig. 10.—Ditto (End View). Fig. 11.—Ditto (Plan). Fig. 12.—Core-box (Plan). Fig. 13.—Ditto (Section). Fig. 14.—Section of Lathe-bed, showing two Sorts of Clamping Plates. Fig. 15.—Fly-nut. All Figures drawn to Scale of 3 in. to 1 ft., or quarter size.

In the second class of lathe users I would place all those who have room enough to keep the lathe as a separate machine, and I would not recommend such to have less than four inches intervene between the lathe centres and its bed.

Table and bench lathes are usually mounted on short legs four or five inches long, by which they are fastened to the bench or table, the fly-wheel having a separate existence; while in the other class of lathes, which I believe has no distinguishing name, the fly-wheel, treadle, bed, and headstocks are all secured to the same legs.

In this paper I will take the four-inch centre lathe for my model, but it will be easy for anyone to make a lathe of a different size just in the same manner, always remembering that everything must be reduced or enlarged nearly in the same proportion. I would say a word of caution to those who think of making a very tiny

lathe, and expect to have it in every way as perfect and efficient, for its size, as a large one. It can be made as perfect, nearly, but it will not be as efficient: neither would a miniature man-of-war. Such a lathe would be almost as troublesome to make as one of a larger size, and would not be anything like as handy or as useful. My advice, then, to the readers of Work is: If you have room for it, make a lathe of four-inch centre such as I will describe in this paper.

With regard to the next question—Where can I get castings?—my advice would be to send your own patterns to the foundry and get castings off them. That is what I generally do myself, and I find it pays, not alone in cheaper castings, although this is also the case, but the experience in pattern-making is valuable, and the consideration of the various stresses to which the tool will be subjected when finished, and the provisions made to resist them, are useful exercises in theoretical and practical mechanics. While, however, this is true for me, others might find it more convenient to purchase the castings ready to work up, and it is not difficult to do so now, as most lathe-makers are sensible enough to supply castings at fairly moderate prices. A glance at the advertisement sheets of Work would give addresses of makers, and I shall be always happy to supply information to those who seek it through "Shop."

To make this four-inch centre lathe *easily*, the use of a good six-inch centre lathe, with slide-rest, also planing machine or shaper, would be necessary; but it can be made *successfully* with a much smaller outfit, consisting, at the least, of a hammer, cold chisel, file, some sort of lathe (the dead-centre one I formerly described would do), and a machine capable of boring a hole $\frac{7}{8}$ in. in diameter through cast iron. To this I must add screwing tackle.

We will begin by making the patterns for the two headstocks, pulley, hand-rest socket, ties, and clamping plates. They should be made of yellow pine or mahogany, and carefully finished with sand-paper. If they were required as stock patterns they should get five or six coats of varnish, but as we only want one set off them they will do very well without. I may mention here that "off" is the technical word used to express that castings are required from these patterns.

The patterns for the headstocks, pulley, hand-wheel, clamping plates, and tees are exactly like the castings, but the hand-rest socket differs somewhat, and will require a core-box.

*Headstock Pattern.*—Figs. 1 and 2 represent the fixed headstock pattern. It will be seen that the vertical ends are nailed firmly to the baseboard, and the corners filled in with pieces of wood which act in the double capacity of strengthening the casting and making its contour graceful. The bosses towards the top are to lengthen the bearing for the mandril. It will be noticed that the centres of these bosses are $4\frac{1}{16}$ in. from the base; the extra $\frac{1}{16}$ in. is to allow for the shrinkage of the metal and for chipping and filing the base flat. The bridge-shaped piece underneath is to strengthen the base; note that this piece itself is in turn strengthened where the holding-down bolt will pass through by putting a piece at each side, as shown in Fig. 3.

A matter of great importance in pattern-making is taper. All patterns should be smaller in the parts which go deep into the sand, so that they can be withdrawn without breaking the mould. The dotted lines in Figs. 2 and 3 show, in a much exaggerated scale, how taper can be given to these patterns. It is only necessary to have the centre of each part slightly thicker than its edges: $\frac{1}{32}$ in. would be quite enough.

*Pulley Pattern.*—It is well worth considering whether the pulley for this lathe ought to be of wood or cast iron. If the latter is used, it will be found to be by far the most difficult piece of metal-turning in the entire job, and should not be lightly undertaken. However, as I have already described a wooden pulley, I give in Fig. 4 a drawing of the pattern required for a pulley such as we will use in cast iron. The hollow at one side is to lighten it, as if made solid it would be inconveniently heavy. The pattern would be turned out of a piece of mahogany $2\frac{1}{4}$ in. thick, well sand-papered, and having the steps tapered so as to leave the sand without difficulty. I prefer gut to a flat belt as a driving band in a lathe of this description, which will be used mostly for wood and light metal turning.

*The Bed.*—It will be necessary at this stage to consider what sort of a bed will be used for this lathe, and where it is to be got. I would not advise the amateur to make a pattern of his bed for the following reasons: first, it takes a large quantity of valuable wood, for not alone must the pattern of the outside be made, but a core-box for the space inside must also be supplied. Then, when the bed is cast, it must be planed, and as they cannot usually do that at the foundry, it must be sent to an engineering establishment, and the cost will be great—so great, that a bed could be got from R. A. Lee, High Holborn, or some other maker, ready for the headstocks, for almost as little as the planing would amount to. An amateur might, indeed, file a bed fairly true, but the work would be very long and tedious, and straight-edges, surface-plates, and other expensive tools would be actually requisite. If any of my readers, however, wish to have a description of a lathe-bed pattern, they have only to ask for it through the proper quarter, and I will be happy to supply it.

A very common practice is to mount iron headstocks on a wooden bed whose upper surface is protected by plates of flat iron screwed firmly to it, and filed true on top and edges. This plan I would heartily recommend to my amateur and apprentice friends. At any future date, if they are found to be worthy of it, the headstocks could be mounted on a more permanent base. In any case, I will go on the supposition that the space between the two sides of the bed is $1\frac{3}{4}$ in. wide. I now pass on to the

*Loose Headstock or Poppet Pattern.*—It is shown in Figs. 5 and 6. I usually begin by preparing the upper cylindrical part, which is 6 in. long and $1\frac{1}{2}$ in. in diameter when finished. One end is enlarged somewhat to take the disc, which will be screwed against it. I cut spaces in this, half through, for the supports to fit into tightly. I find this plan much easier than cutting a semi-circular hollow in the vertical pieces would be.

The only thing to note in this pattern is to have all the corners nicely filled up with putty. The piece *a* should be carefully put in so that when the locking-bolt is passed through it will not weaken the support too much. The piece *b* need not necessarily be there at all, but it will serve to make the supporting base larger. The tenon which is eventually to go between the sides of the bed will be $1\frac{7}{8}$ in. wide in the pattern to allow for shrinkage and fitting.

*The Hand-wheel Pattern* (Figs. 7 and 8) can easily be turned from a piece of mahogany 4 in. in diameter and 1 in. thick. I show it without spokes, simply a disc, but spaces could be cut out by anyone who does not mind the trouble. Hand-wheel patterns can be got at most foundries.

Hitherto, all the patterns have been just as the castings will be. In the hand-rest socket pattern two new features in pattern-making become prominent. The first is the piece *b* (Fig. 10), which should be loose, simply held on by a pointed piece of wire; or, better still, let down from the top with a dovetail as shown by the dotted line in Figs. 10 and 11. This piece is placed at an angle of 45 degrees with the length of the socket, as is seen clearly in Fig. 11. We want a slot cast in the socket base like that shown by the dotted line in Fig. 10. This could be managed only by means of a *core*, which I will now endeavour to explain.

A slip of wood the exact width which the slot is required to be is nailed centrally along the base and its entire length. This is called a *core-print*. We next require a *core-box*, which is shown in Figs. 12 and 13. It is made of four strips of wood nailed together as shown, and two other pieces tacked to the ends to keep them the correct distance apart. The moulder fills the space with sand pressed firmly together and mixed with some liquid which makes it quite firm and hard. When dry it is a T-shaped strip of sand, which is placed in the mould in the space made for its reception by the print. When the casting is made the sand can be shaken out, and in its stead will be the T-shaped recess or slot.

A couple of tees had better be cast, as they are cheaper than wrought-iron ones. The stems will be 3 in. long and $\frac{7}{8}$ in. in diameter, and the horizontal pieces tacked to them $\frac{1}{4}$ in. thick and $\frac{7}{8}$ in. wide at the centre, tapering to $\frac{5}{8}$ in. at the ends. They may be 8 in. and 4 in. long respectively. The tees used for iron-turning are flat on top, and could easily be made by nailing flat strips of wood $\frac{1}{2}$ in. thick on the ends of the stems.

*The Holding-down Plates* may be made of either wrought or cast iron. Their shape will depend somewhat on the construction of the lathe-bed. They are mostly pieces of wrought iron having the ends slightly turned up and the space between wide enough to embrace the underneath surface of the bed. Sometimes, however, they just clamp the upper cheeks. In Fig. 14 I give the section of a lathe-bed with the two sorts of clamping plates, shown at *a* and *b*. That at *a* would pass over any stays which might be cast in the bed, but should either be screwed tight from above or have a nut attached to a tube and handle to clamp it; *b* is suitable for a plain bed without stays.

The last pattern we will require is one for *Fly-nuts*, about the easiest of which to make is shown in Fig. 15. The centre boss is turned, as are also the arms, and they are driven into holes bored into the boss. The point of juncture is then filled up nicely with putty. The arms need not be quite as long as shown in the figure, but I like to have a good purchase. It would be as well to get a plain round disc cast also. It is to fit at the end of the poppet, and will be $\frac{1}{4}$ in. thick and $1\frac{7}{8}$ in. in diameter.

If any of those who follow my instructions in lathe-making will construct all these patterns nicely, well enough to please the moulder, they will get some useful practice in joinery which will pave the way for more important undertakings, and teach

them a good deal about the various parts of a lathe.

I will suppose that they are now sent to the foundry, and in my next article describe what is to be done when they are returned with the castings.

## HOLDFASTS FOR WOOD-CARVERS, ETC.

BY OPIFEX.

ORDINARY CRAMPS — OBJECTIONS — SUGGESTION No. 1—SUGGESTION No. 2.

*Ordinary Cramps.*—One of the first essentials to success in wood-carving is the possession of some efficient means of holding the work steady and solid upon the bench, table, etc., and, as far as my experience goes, the cramps to be had in the tool market are inadequate; at least, I have not been fortunate enough to find, either in the shops or in any of the numerous illustrated price lists advertised, any appliance of this nature which is entirely satisfactory. This, I grant, may be my misfortune, or my fault, or both, and the "very thing" may be easily obtained by one who knows where to look. Be this as it may, however, pending the discovery, I have had recourse to several devices from time to time, some of which have been rather successful, and I therefore venture to offer two of them, by means of the accompanying drawings, to any reader who may require such things, and who, like myself, rides his hobby in fields remote from those centres of attraction, the tool shops.

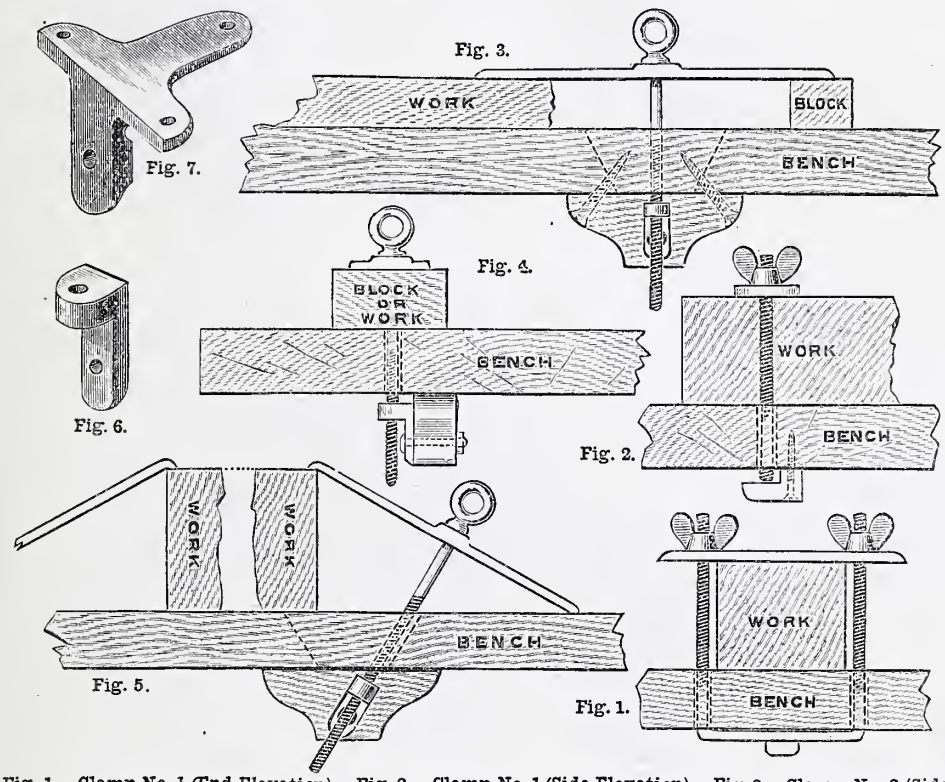

**Fig. 1.—Clamp No. 1 (End Elevation). Fig. 2.—Clamp No. 1 (Side Elevation). Fig. 3.—Clamp No. 2 (Side Elevation, showing details). Fig. 4.—Clamp No. 2 (End Elevation). Fig. 5.—Clamp No. 2, showing Method of using two Clamps. Fig. 6.—Sketch of L-Piece. Fig. 7.—Suggestion for Cast Bracket. Figs. 1, 2, 3, 4, 5 are on Scale of 1½ in. to 1 ft. Figs. 6 and 7 are not drawn to Scale.**

The chief objections to the ordinary clamp or cramp—which is it?—are that it does not reach far enough, that it is more or less "wobbly," and that it can only be applied at or near the edge of the bench, etc., whereas it is often desirable to apply pressure to a point altogether beyond its reach, especially in wide and thin subjects.

*Suggestion No.* 1.—Fig. 1 represents an old and, to me, a valued friend, or rather one of a pair, which I have found very useful for many purposes other than carving.

These are easily made, and are very suitable for holding long and narrow work—say, from 6 in. by 6 in., and any length down to the thinnest stuff.

To make the pair we only require two pieces of ½ in. round iron, of good quality, and about 27 in. long; run a good screw thread on each side, six or seven inches in length. Bend at right angles at points 10 in. from the ends, and provide for suitable thumb-nuts; also two plates of ⅜ in. by 1½ in. iron, 9 in. long. Drill out holes seven inches apart, or to suit the exact width of the clamps, and sufficiently large to allow the threaded ends to pass freely through.

Fig. 2 explains the method of using these clamps, from which it will be seen that each clamp requires two holes through the bench, and also a button of hard wood of any kind to prevent the clamps from falling through, but which allows of their removal when not in use.

*Suggestion No.* 2.—Figs. 3—5 will, I hope, give the reader a correct idea of the construction and mode of using another form of clamp, which will also be found effective by wood-carvers and wood-workers generally.

In its simplest form it consists of an L-shaped piece (Fig. 6) of cast iron, pivoted to a hard wood bracket, which is attached by strong screws to the underside of the bench.

A threaded rod of ½ in. round iron, provided with an eye and shoulder at the upper end, passes through ¼ in. by 2 in. by 10 in. steel plate and through a tapered slip or mortise ⅝ in. wide and about 5 in. long at top, tapering to 3 in. at bottom.

The L-shaped piece is accurately tapped to suit the threaded rod, and is held in position by a ⅜ in. cheese-headed bolt and nut passing through the wood bracket.

The cramp may thus be applied to work in a horizontal position, the other end of the plate being levelled up with a block of wood, etc., as in Fig. 3, which is a front elevation, and Fig. 4, end elevation; or the clamp may be applied to the work at an angle, as in Fig. 5, the pivoted L-piece and tapered opening allowing the pressure of the rod to be applied at right angles to the plate.

Another similar clamp may be placed in line at a suitable distance upon the bench, when, if several plates of different lengths are provided, the pair may be applied to various sizes of work in the manner suggested at Fig. 5.

The "weak spot" in the appliance as described above is the wooden bracket, and although I have found it work very satisfactorily for a considerable time, I can only regard it as a makeshift, and therefore recommend a casting something like Fig. 7, which, with the other parts as already described, would make a good and reliable bench holdfast.*

## STAGE PERSPECTIVE.

BY WILLIAM CORBOULD.

OBLIQUE OR ANGULAR PERSPECTIVE.

My last article finished with the first rule in perspective; we now come to the second: oblique or angular perspective. The difference between the two rules is that in the first rule the point of sight is invariably fixed in the centre, but in the second rule the point of sight may be shifted to the right or left of the centre of the horizontal line; the points of measurement, *a*, *a*, in Fig. 4, become the vanishing points, all receding lines above and below the horizontal line falling into those points.

In Fig. 4 in the next page, if you were to place a square block with one corner towards you, it would appear in oblique perspective. Should you wish to represent a building, or anything perfectly square, you would draw your first perpendicular line, *b b*, then the base line, *c c*. Supposing your block to be 10 ft. square, you must mark 10 ft. from your perpendicular line each side to points at *c*, *c*. From the front corner draw a line to vanishing points, *a*, *a*, on the horizontal line, A A; this would be the ground line of your block; the height, of course, would be 10 ft. marked on the perpendicular line, *e*, it being a square we are working with; but a building might be any height. When the proper height is settled, a line drawn from that point, *e*, to the vanishing points, *a*, *a*, gives the top perspective line of the block or building. To find the proper perspective of the two sides, draw lines from dots, *c*, *c*, on the base line each way to points, *a*, *a*, on the horizontal line; where the lines intersect the ground line, *d*, *d*, you place the two perpendicular lines,

* Since this paper was in type, the suggestion in the last paragraph has been acted upon by Messrs. Booth Brothers, Upper Stephen Street, Dublin, to whom the ownership of the design for No. 2 Clamp has been transferred, and very soon it may be obtained from them either in the form above described or otherwise improved or modified as their wide experience in such matters may suggest.

*f*, *f*, which completes the two sides of the block ; *g* is the distance point.

I will now illustrate this by supposing we have a scene, as in Fig. 5, which shall represent a roadside inn, standing at the junction of two roads looking right and left, consequently drawn in oblique or angular perspective. It will be seen that the lines of the house and roads, fencing, etc., fall into the vanishing points, *a*, *a*. The point of sight, or distance point, is shown at A.

In drawing this picture, first settle on your horizontal line, *a a*, and vanishing points, which are shown at *a*, *a*, those dots being on the horizontal line, and also the distance point or point of sight, A. The base corner of the building is shown where your first perpendicular line, *e*, Fig. 4, rises, which would be to the right of the point of sight. Draw this first line, using your plumb-bob line for that purpose ; you may measure all other perpendicular lines from the first one, as it will be perfectly upright. The line *b b* is the base line.

Now dot the height of your doors and windows on your first perpendicular line, as at *b*, *b*, *b*, Fig. 4, by holding the line which you have hooked in at one or other of your vanishing points, *a*, *a*, on to the dots marked on your perpendicular line, drawing it tightly (see Fig. 6). In the other hand you have a piece of charcoal, and make a dot where your cord crosses the outer perpendicular line, *c*, Fig. 4. After you have completed all your dots, take the straight-edge, draw lines from dot to dot, and set the doors and windows out on these lines. The lines of the roads, water-trough, etc., are obtained in the same way.

By this time you will have become pretty well used to your two lines or cords—that is, you will have found out that you cannot draw a correct scene without them. The base line in Fig. 5 is 15 ft. along the front of house, and 5 ft. the other way.

I want you to well study the two rules I have shown and made as simple as possible—that is, "parallel," and "oblique or angular perspective," because every scene or study you may have to do must be done under one or other of these rules.

I wish you to bear in mind, however well a scene may be painted, one line wrong in the perspective would spoil the whole.

I had better here explain the meaning of the point of distance, which means the spot where the spectator is standing from the scene, looking straight before him, without turning the head to the right or left, depicting only what he sees while so doing.

Supposing that you were to have a large hoop fixed in front of you, so that the eyes caught the edge of it, you are looking through this to the far distance—looking, as it were, through a funnel, by way of illustration—every object getting smaller and smaller as it recedes from the eye, all falling into one spot, which would be the small end of the funnel or dot, called the point of sight : this constitutes the rule of parallel perspective.

In angular perspective, as an illustration, if you place yourself opposite a square block set angularly, and look steadily at the corner near you, without moving the eyes, you will find you can only see a certain distance right and left—that is to say, you see the outer rim of a circle ; now, it is on the rim of this circle that the two measurements or vanishing points are fixed (see *a*, *a*, Fig. 5) ; A being the spot at which the spectator is supposed to stand.

The part of the circle you are looking through would be within an angle of 60°—that is, a section of the whole circle of 360°, that being six times 60° ; you would have to turn yourself six times before taking in the whole circle of 360°, comprising a panoramic or bird's-eye view ; I mean before you could sketch all the objects you would have to take six different turns, you being the centre of this panorama. The panorama, which was called "Niagara in London" was a splendid illustration of this.

We have now come to the drawing of a few objects by the aid of these two rules, which are simple enough in themselves and easily understood. It requires a little practice to do the work with facility, but this may be obtained by working on a tolerably large scale on paper. It will render the work all the more easy when the beginner commences outlining and painting on the canvas itself.

## SCRIBING-BLOCKS:
### THEIR USES, AND HOW TO MAKE THEM.

BY J. H.

THE scribing-block or surface-gauge is indispensable to the fitter and turner, and extremely useful to the pattern-maker. Where compasses, compass callipers, scribers, and rules would be of no use for the marking of centre, and various other horizontal lines, the scribing-block is of service. No matter how irregular a face, or how many faces there are which bear no relation to any other faces, lines can be carried along them all with a scribing-block in a true plane, or in various planes parallel with one another. The marking-off table, or the surface-plate, supplies that true basis which is wanting in the piece of work itself, whether it be rough casting or forging. The scribing-point of the surface-gauge being clamped in any required position, and brought against the vertical face of the work, the broad base is slid over the marking-off table or surface-plate, and the point travels perfectly parallel therewith along the face of the work. Or the turned-down point tests the parallelism of an upper face of a piece of work true in itself, with the face of the table, preparatory to the marking off of some other portions of the same. Or heights and dimensions are transferred more directly and more accurately by means of the scribing-block than they can be by the compasses, particularly when the faces on which they are measured slope diagonally. Chucking centres are also marked upon work which has to be turned, the work being laid upon packing-blocks of V or other shape, and turned round into new positions, after the scribing of lines across the ends, the mean of all the lines, or their points of intersection, being the true centre for chucking.

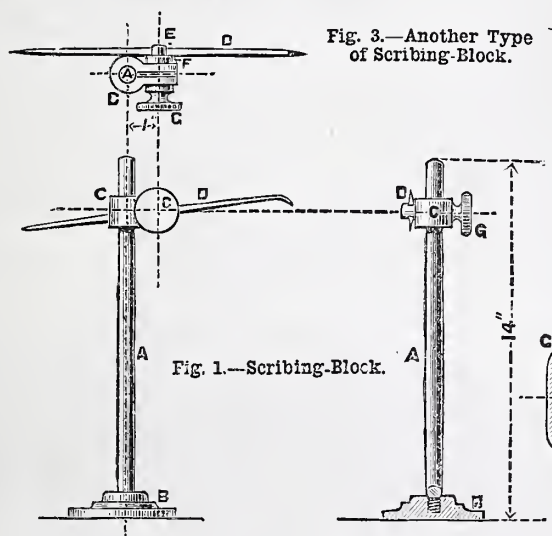

Fig. 1.—Scribing-Block.

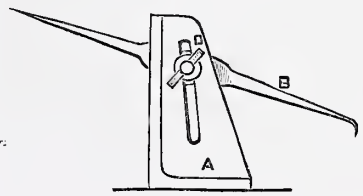

Fig. 3.—Another Type of Scribing-Block.

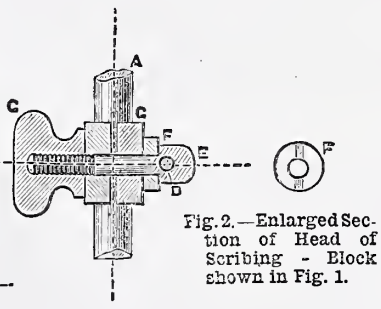

Fig. 2.—Enlarged Section of Head of Scribing-Block shown in Fig. 1.

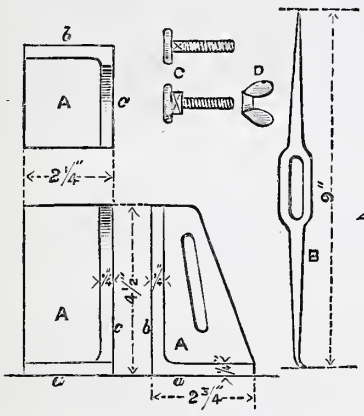

Fig. 4.—Details of Scribing-Block shown in Fig. 3.

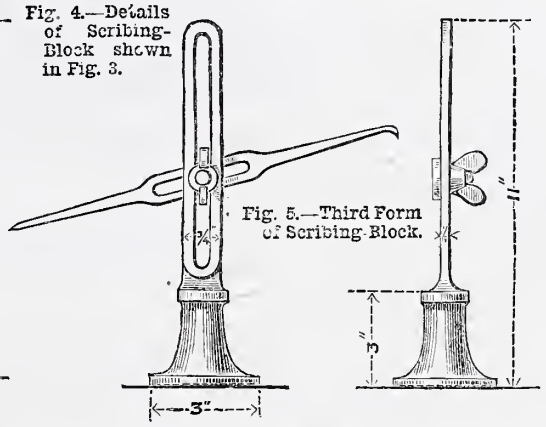

Fig. 5.—Third Form of Scribing-Block.

These scribing-blocks are made in many modified forms, according to taste. The essentials are to have a broad, steady, and somewhat heavy base, and ease of movement of the scriber leg, and stability.

I show three forms of scribing-block, in which these conditions are fulfilled.

In the first form, illustrated in Figs. 1 and 2, there is a rod, A, of iron or steel turned to $\frac{1}{2}$ in. or $\frac{7}{16}$ in. diameter, and screwed into a base, B, of cast or of wrought iron. A divided block, C, slides upon this rod, and carries the scriber-point, D, which swivels to any angle, along with the tightening-screw, E, and washer, F. The sliding-block is shown enlarged at Fig. 2 for clearness. To make it, proceed thus:—

File a block of forged steel or wrought iron to the outline of the block, C, in Figs. 1 and 2. Drill a hole through it in one direction for the pillar, A, and another at right angles therewith—say, about 1 in. away from the centre of the first hole for the tightening-screw, E. Then, with a hack-saw, cut the slit carefully and parallel with the sides, so giving the elasticity required for pinching up the block.

The pin, E, will be turned down from a bit of rod, originally of the diameter of the head, and screwed about as far along as shown. A hole is drilled to take the scriber, D, which, it will be noted, is of circular section, and the precise position of the hole is of vital importance. Observe that it is drilled to come just a very trifle under the face of the washer, F, and the face of the washer is hollowed across to a corresponding depth to allow the scriber to lay against it, so that the washer and scriber turn together. When the screw-bolt is pulled hard with the milled head, G, the effect is therefore to pinch the scriber between the head and the washer.

The milled head is made of steel, iron, or brass. Turn and mill it first between centres, cut it off, and then drill and tap the hole for the screw. It is better, to ensure truth, to drive the milled head into a hard wood chuck, or hold it with the dogs and drill in the lathe than to drill in the vice.

Another and quite different type of scribing-block is shown in Figs. 3 and 4. It is a form which possesses the merit of great steadiness, but involves a little bit of pattern work and casting. There are three parts—the base, A, in cast iron or gun-metal, the scriber, B, the screw, G, and wing-nut, D.

The pattern of the base is like its casting, and the slot can be cast out by using a print and making a core-box—making it a little narrower than the screw to allow of cleaning out with a file. When cast, plane or file the three faces, *a*, *b*, *c*, at right angles with one another; and smooth over the other parts with the file, for the sake of good appearance.

The scriber, B, is made of steel, first roughed to outline on the anvil, then filed flat and parallel about the central portion, upon which the parallel lines forming the slot and the bounding metal will be marked and filed. The tapering ends may be turned for a portion of the distance out from the centre, but it is not necessary, as a little rough grinding, followed by filing, will bring them to a good shape.

The screw, C, is provided with a turned head and a square shoulder, to fit the slot, A. The wing-nut, D, is cut from iron, steel, or gun-metal—either will answer.

Another scribing-block is shown in Fig. 5. In this the stand is made of wrought iron entirely, the slotted portion being swaged down from a piece of 3 in. bar. The bottom is turned up to any good outline, and is hollowed at the bottom to rest only upon an annular ring of metal. The slotted part is then filed to thickness, equal sided from the chucking centre, and the slot and the outside edges lined out. Holes are drilled in contiguity for removing the bulk of the metal and the slot filed out.

Some trouble might be saved by making the slotted portion distinct from the base. The former would be of wrought iron, and the latter might be either wrought or cast. The scriber itself and the tightening-screw and wing-nut are like those shown in Figs. 3 and 4.

The dimensions given are not hard and fast. They are only given to assist in forming some idea of suitable proportions for blocks made either larger or smaller in size.

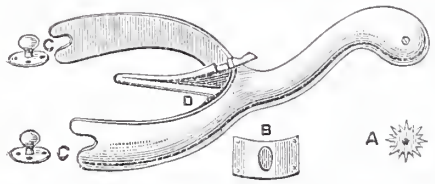
The height of a scribing-block is not of much importance, because when necessary for marking off work so high as to be beyond its range, it can be always raised up and slid along on a parallel block of iron placed upon the marking-off table. This is frequently necessary, and pieces of T-iron and channel iron of different depths, but planed truly parallel, are kept by the marker-off for this purpose, and also for blocking up work upon.

## SPURS WITH CONCEALED ROWELS.

BY J. C. KING.

To those who have been visitors to English or foreign museums, anything new in the way of spurs will come as a surprise. So small a utility, and with such limited topical fixture, there seems but little chance of improvement. This little seems attained by a larger head—as the knob end is termed—and by having two holes in the rowel, a centre one for free turning, and an eccentric hole to make the rowel a fixture, concealed in the notch of the head of the spur, as shown in the illustration. A screw instead of a rivet is used, so that with the point of a knife, in absence of a bradawl, the screw can be removed and rowel placed just as wanted, in or out of sight.

The object to be gained is that spurs may be worn in company, where projecting rowels are apt to catch in dresses and cause snags and rents, more especially in ball-rooms. The inventor could not keep to his one idea of the rowel, but tried to simplify the fixing in the heel of the boot, now done by the pressure of a box-spring built into the boot-heel when the boots are made. It is a doubtful fixture at best. Spurs are often lost, or boxes get out of order. Their general faultiness prevents them from being adopted for the rank and file of cavalry corps, which mostly have a long screw passing right through the heel, screwing into the end of



**Spur with Concealed Rowel—A, Rowel; B, Plate over Box to take Spring; C, C, Studs to receive ends of Spur; D, Spring.**

one of the bows of the spur. This is a clumsy way, the projecting screw-point sometimes snagging the trousers in walking. The method of holding the spur into the boot-heel is by a shield-plate with an oval hole. To catch in a hole in the heel of a boot, a spring fixed to the tang of a spur, with a notch in it, catches into the shield-plate and holds it securely. To release it, the projecting end of the spring is pressed down at the same time as the spur is pulled out.

Additional support is given by two strap-studs fixed on the fore-parts of heel sides, and the bow-ends of the spurs have a fork notch to hold to these strap-studs. These studs, by the straps, keep the trousers down. For jack-boots, the jockey-spur is best, and is always used with them in the army or hunting field. Some people imagine the spur inflicts harm on a horse. It is not the actual prick that can ever do harm, but the impulse it gives to a horse, which the voice may equally do, to urge to over-exertion. No one should ride without spurs. They may save the rider's life from the flinching of a shying horse being diverted by the spur.

They, moreover, teach a novice to keep his feet pointing straight forward, to keep the rowels away from the sides of a high-mettled horse. The sorry hacks do not mind them; hence the uncouth riding of most of our mounted police, and not a few would be cavaliers in Rotten Row. The inventor is the author of a pamphlet on "Riding," and gives this spur to the readers of Work if they think it worth adopting.

## OUR GUIDE TO GOOD THINGS.

*** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of Work for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of Work without charge, the notices given partake in no way of the nature of advertisements.*

### 66.—Sloane's Adjustable Gauges for Perforating Machines.

There are, doubtless, many paper-rulers, book-binders, and account-book makers among the professional readers of Work, to whom the description of an adjunct to perforating machines, invented and supplied by one of their own trade—namely, Mr. Thomas C. C. Sloane, 59, South Castle Street, Liverpool—will prove interesting, if not useful. It appears, from what Mr. Sloane himself tells me, that the merit of the invention consists in putting into the hands of book-binders, etc., a substitute, in a permanent, reliable, and ever-ready form, for some make-shift intended to achieve the same purpose, which is to be found in many workshops, it is true, but in so crude and untrustworthy a shape that it is next door to useless. Now many sheets—such as coal ticket and other check books—require several perforations on a sheet to overcome the difficulty of there being only one back "lay," and so users of perforating machines are driven to adopt various methods for securing "lays"—such as tacking or gluing strips of millboard on the front board, or making use of printers' quoins in the same manner, or even putting pins or pencil marks on the front board. It is clear that all such means are, to say the least of them, clumsy, calculated to waste the workman's time, never ready to hand when most wanted, and certainly unreliable. Mr. Sloane, however, claims that his gauges, on the contrary, are neat and handy, economisers of time, always ready for use, and such as may be always depended on. He says that when some look at the illustration of a perforating machine thus fitted, as shown in Fig. 1, they think that space is lost by having to come over some of the gauges; but this is not so, as the "lay" is set to suit the sheet, and all sheets that follow are bound to be the same. The nature of Mr. Sloane's appliance will be easily understood from Fig. 1, in which an ordinary perforating machine is shown fitted with five of the adjustable gauges, while Fig. 2 shows a sheet perforated once vertically from top to bottom and four times crosswise, the horizontal perforations being obtained by laying to four of the adjustable gauges. Fig. 3 shows one of the gauges by itself and off the machine. It also shows how they are secured—namely, by a short screw-bolt passing through the centre of the gauge, whose head is tightened on the gauge with a pressure sufficient to retain the gauge in position by a wing-nut which works on the screw. Yes, possibly some may say, "But how is the attachment to be managed? for there are no means whatever of attaching and securing the gauges to the perforating machines which I possess." The reply is, that it is necessary to modify the machine and render it fit to receive the gauges, and this is managed by cutting a slot parallel to the back lay right through the centre of the front board, leaving, as a matter of course, a portion of the board not cut through at the front and back edges for strength. This slot—which is clearly shown in Fig. 1—should be ⅜ in. in width. This done, the gauges must be placed on the board at the needful distances from each other, and having got them in due parallelism, put the bolt through each gauge and fasten from below with washer and nut. To set the lay, place the sheet under the teeth, and adjust the various lays, commencing with gauge No. 1, as in Fig. 1, draw sheet towards you, and set gauge No. 2, and so on. Prepare in the same manner, commencing with gauge furthest from the operator, who must draw the sheet towards him after each perforation. For use of gauges on back board, the slot of old back guide is made available, using large washer supplied to use with wing-nut. The gauges are made of wrought iron, and are supplied with fittings, washers, etc., complete, for 15s., or 15s. 6d. post free.

### 67.—Coulthard's Designs for Fretwork, etc.

In an early number of Work I spoke of these designs as being not only cheap but really and truly well suited for beginners, who are too often disheartened by commencing work on a difficult and intricate pattern. Mr. Coulthard, East Cliffe Terrace, Bournemouth, sends out a variety of designs in fretwork, stencilling, and turning at from 1s. to 2s. 6d. per packet. I believe I am justified in saying that any further information will be readily supplied by Mr. Coulthard to any applicant. Some have considered the designs somewhat rough in execution. Being from stencil plates some are unavoidably so, but the edges can always be set right with a camel-hair pencil and some Indian ink. The Editor.

## SHOP:

### A Corner for Those who Want to Talk It.

*** *In consequence of the great pressure upon the "Shop" columns of* Work, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—Letter from a Correspondent.

**Boiled or Unboiled Oil?**—A Weekly Subscriber writes:—"Having taken in Work from the beginning, and derived pleasure and knowledge therefrom, I should feel greatly obliged to have the benefit of practical men's experience as to whether boiled or unboiled oil is the best for external use. In a week or two I purpose painting my house outside, and am anxious that it should have a varnishy appearance, but cannot ascertain the proper oil to use for that purpose. I have consulted four different house painters. Two of them say it must be boiled oil, and two exactly the contrary. Under these circumstances, I went to a shopkeeper who sold only paint to have his opinion, and he said oil that was not boiled must be used. After such conflicting opinions, I should much like Work to decide the question, as I do not wish my house to have a dead, flat appearance a few weeks after it has been painted, but to look after two or three years as if it had been varnished. Perhaps, therefore, some of your practical correspondents will kindly inform me with certainty how the desired end can be accomplished. Also what good iron gutter for rain from the roof ought to cost per foot or yard."

### II.—Questions Answered by Editor and Staff.

**Field's Boiler.**—E. S. (*Birmingham*).—I do not know the registration number of this boiler, but you can obtain all particulars regarding it from Messrs. Lewis, Olrick & Co., Leadenhall Street, London, E.C.—F. C.

**Contributor's Address.**—R. A. B. & Co. (*Kensington*).—We do not give the address of any contributor. Send a stamped, sealed, and addressed letter, and it shall be forwarded.

**Paper for Stencil Plates.**—Stencil.—I am not aware of any paper specially made for this purpose; that in ordinary use is a stiff cartridge. To make it resist moisture from the colour and endure wear, some persons soak it in linseed oil, others go over it with "knotting." This latter is to be preferred. Knotting is used for going over knots in wood before painting, and may be bought at the colourman's. Another useful paper for stencil cutting is that known as "oiled foolscap." The original use of this is to lay between the sheets in the copying-press, and the larger stationers sell it. Its character is that of a thick tracing-paper. A drawn or printed design can be seen through and traced upon it, which is often a great advantage. It needs no further hardening.—S. W.

**Mirror.**—Old Furniture.—To re-silver the parts of the mirror which have been scratched will be a difficult job, but if you wish to have a try, the silver process will be decidedly the best. You must make up two solutions, as follows: Dissolve 75 grains of nitrate of silver in 3½ ozs. of water; add dilute ammonia cautiously until the precipitate is nearly dissolved: there should be a small quantity undissolved at the bottom. Should too much ammonia have been poured in so as to take it all up, a drop or two of silver solution must be added, then shaken well and left to settle. Bottle and label A. Second solution: Dissolve 15 grains of nitrate of silver in 6 drams of water, and warm the solution. Next dissolve 12 grains of Rochelle salt in 3 drams of water, and when completely dissolved add to the silver. Stir well, and set to boil for about ten minutes; filter hot, and make up to 16 ozs. with distilled water. Bottle and label B. Form a wall of beeswax or putty round the spot to be silvered, mix half of A and half of B together, and pour on the glass. Let it stand about an hour, then wash carefully. One great difficulty will be to clean the glass, as it ought to be chemically clean for the silver to deposit properly. This is done by washing with potass water, acid, and alcohol, and washing with water between each operation, finishing off with distilled water.—W. E. D., Jr.

**Mosaic Work.**—H. F. B. (*Barking*).—The pieces of glass for this, perhaps, you will be able to obtain of Messrs. J. Powell & Sons, Whitefriars Glass Works, Temple Street, London; or if not, they will, I think, be able to tell you where to get it. Write to them, *enclosing stamped envelope;* you can, if you like, refer to this answer.—W. E. D., Jr.

**Scrapers.**—Hodge.—Yes, surfaces can be got up more accurately with a scraper than with the finest files; but as the files cut faster than the scraper, this last tool should not be resorted to till the surface-plate and straight-edge show the surface is nearly true. There are many kinds of scrapers. Take an old "three-square" file—a large saw-file will do—say 5 in. long; grind the point for about 1½ in. on each of the three sides till the teeth are quite gone and the ground surfaces are very slightly rounded. Now rub them on an oilstone till each of the three edges is quite smooth and nearly, but not quite, straight. Now you will find you can scrape cast iron, steel, and wrought iron surfaces, taking off the metal just where you want to. For brass, the three-square scraper is too greedy, as it has an angle of about 60°. For this metal take an old flat file—a 6 in. file would be suitable—about ¾ in. wide; grind the end of this off perfectly straight and square, then it will be perhaps ⅛ in. thick; this must be reduced to about $\frac{1}{32}$ in. by grinding the flat sides. Thus you will obtain two edges, which you must finish, as before, on an oilstone till they are perfectly smooth and very nearly straight, just slightly rounded when laid on a flat surface; the end surface must also go on the stone by rubbing it while in an upright position. On wrought iron the scraper will not cut very smoothly without a little water or oil. These two scrapers are quite sufficient for all the work on the ¼ horse-power engine. The gentleman who lives at "the Hall House" could give you much useful information.—F. A. M.

**Finishing Turned Surfaces.**—Hodge.—I don't know how to give a short answer to this. If you only want to do such work as is required in the ¼ horse-power engine, you can do very well without any scraping in the lathe except for brass. You can scrape brass with the flat scraper just described if you put the T-rest a little way off, say ⅛ in., and then apply the scraper, with the handle held high and the point of the tool pointing down below the centre of the work. This causes the edge to present in a proper way, and also gives some elasticity, which absorbs the vibration. In the slide-rest you would require a spring tool; but as I don't think you need one, I will not describe it here. If chattering occurs in brass, you can remove it by taking a light cut with a point tool, or with a file, used as the work is running in the lathe. For finishing small iron work when turned and filed smooth in the lathe, you can do well enough with two grades of emery-cloth; but if you want to polish a larger surface, such as the rim of a 16 in. fly-wheel, take a piece of deal about ⅞ in. square and 1 ft. long, oil the end, and dip it into coarse emery powder; squeeze the powder into the wood, then put up the hand-rest and use the wood polisher like a tool, pressing it hard against the revolving surface. It takes some time to get a nice polish; the emery has to be constantly renewed, as it drops off the stick. It is hard work, and very dirty, and it will never do to let the emery powder get into your slides or mandril collar. Be very careful about this. You might as well have arsenic loose in the kitchen as have emery powder loose about a lathe. This stick is chiefly useful in curved hollows, into which it soon fits itself.—F. A. M.

**Shafting.**—Hodge.—Shafting can be turned on an ordinary slide-lathe, but it would be done at about half the cost on a special lathe made for the purpose. These have several tools working at once—for instance, there might be a *roughing* tool, adjusted to remove the bulk of the surplus metal, and then would follow, on another slide, fitted on the same saddle, a *finishing* tool, and then the travelling back-stay. The action of the finishing tool would, of course, be carefully watched with callipers, lest the edge should get damaged, and so the diameter of the work should increase. The turner would follow the finishing cut himself with a file and a ring gauge, filing till the ring gauge would pass. The ring gauge itself might be a trifle too large, and then the clamps would be used to grind the whole shaft to the exact size of a second and true ring gauge. Nothing like the same degree of accuracy can be attained by callipers.—F. A. M.

**Hollow Rose Cutter for Making Pins.**—Hodge.—I don't know of anything better than a rose cutter for making ⅝ in. pins from ¾ in. bars. If yours causes the work to jam, that must be because the mouth is too large. Probably it was drilled from that end, and where a drill enters is generally a little larger than the main part of the hole. This might have been prevented by turning away about ¼ in. at the end before cutting the teeth; *now* you might make a grinder to enlarge the hole a little, so as to leave it a little the smallest at the front end. A wooden grinder should do it. Turn a peg ⅝ in. in diameter, bore a hole up about ½ in., then saw it down the middle. Now make a taper pin to drive into the ¼ in. hole, so as to expand it as it wears away. That should grind it out well enough.—F. A. M.

**Incubator.**—F. B. J. (*Liverpool*).—A description of a hot-air machine may appear in the course of a few months. A description of a canvas canoe appeared in No. 80, Vol. II.—Leghorn.

**Rearer.**—No Name (*Maidenhead*).—Your wish may be gratified in the course of the next few months. An article on the subject is in hand.—Leghorn.

**Microscope.**—(1) Micro has a brass tube with a spring and a wooden thimble with lenses, and wants to know how to use it as a microscope. I am afraid I cannot assist Micro. *Is* it a microscope? If so, what about object lens? Is it not rather a part of some kind of instrument or toy? If I could see it I could give better judgment. (2) "Should I need Canada balsam to make objects transparent?" Objects are rendered transparent, and the balsam is used as a transparent cement. (3) "Can I use the cheap camera lucida, recently described, to sketch with?" A camera lucida is used for that purpose, but I do not think you could use it with the instrument you described, as an instrument is needed that has a steady stand or clip for holding the object to be sketched, also focussing arrangement. If the instrument Micro has is a microscope, or part of one, I judge it is nothing more than a simple instrument to use in the hand for examining objects such as flowers, etc.—O. B.

**Bicycle.**—E. G. says that he wishes to build a safety of the "Referee" pattern. The cut of machine shown in his letter is not a "Referee" pattern, but an "Impetus," by the St. George's Cycle Co. As I do not happen to have a "Referee" by me, I cannot give exact measurement of tubes, but the same lengths will make either frame. Accurate lengths cannot be given without a full-size drawing of the machine. Lengths to make the above frame or a "Referee" may be set down as follows, all the tubes being 18 B.W.G.: A, 19 in. × ⅞ in.; B, 16 in. × 1½ in.; C, 16 in. × 1¼ in.; D, 9 in. × 1⅛ in.; E, F (two of each), 16 in. × ¾ in.; tube inside steering barrel, 11 in. × 1 in. With regard to brazing, ample instructions are given in Work ("Safety Bicycle Construction"). The bottom bracket is brazed to the tubes with the end cups left out. These are afterwards sweated in with soft or tinman's solder. If the bracket has no cups, but simply the ends hollowed out for the balls, they, of course, get softened by heat in brazing, and must be hardened by tempering afterwards, when the hollow for the balls is very likely to get out of truth in the process, and the same with the ball-head. To harden, heat each end separately to dull red, and plunge in water.—A. S. P.

**Dark Slide.**—Newcastle-on-Tyne.—Slides for detective cameras are not particularly difficult to make. The protection afforded by the camera permits less accurate workmanship than in other kinds of slides. Very serviceable ones can be made of blackened cardboard and ferrotype plate. Procure some stout, hard cardboard, and cut out some pieces—as many as the number of slides you propose making—half an inch larger in length and

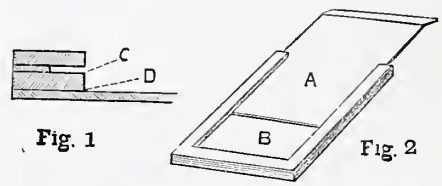

Fig. 1 Fig. 2

**Fig. 1.—Section of Home-made Dark Slide for Camera—C, Groove; D, Recess. Fig. 2.—Slide Complete—A, Shutter; B, Recess for Plate.**

breadth than the plates to be worked. Cut some slips of cardboard a little thicker than the glass of the dry plate, and a quarter of an inch wide, and glue them on to the edges of one side of the card to form a shallow cell to receive the sensitised plate. On these slips fasten other slips made of thinner cardboard on three sides, one-eighth of an inch wide, and on these again other slips a quarter of an inch wide, which will thus leave a groove for the shutter, which is to be made of a ferrotype plate bent at one end to form a cap to the slide, and act as a protection from the light. A coating of lamp-black in gold size, made to the consistency of paint, will complete the matter. The accompanying diagrams will show a section of the frame (Fig. 1) and (Fig. 2) the slide complete.—D.

**Transferring.**—R. W. D. (*Ardwick*).—In the first instance it is necessary to make a negative of the picture to be transferred in the usual manner, for, whatever process is afterwards adopted, much depends on the purpose for which the impression on wood is required (whether for blocks for printing or merely decorative purposes), or to the most suitable process. A slight sketch of how to do it is, firstly, to prepare the wood with a coating of chloride of ammonium in a weak solution of gelatine; drying; then sensitising by brushing over it a strong solution of silver nitrate, in a room lighted with a yellow light, and drying in the dark. The negative is then placed in close contact with the dry surface, and exposed to the light sufficiently long to print the image, which is afterwards washed and fixed in hyposulphite of soda solution, washed again, and dried. Or carbon tissue can be used, and the image transferred from the tissue to the wood direct, in the usual manner of carbon printing. Either process requires a certain amount of knowledge of photographic manipulation to be successfully conducted.—D.

**Simple Camera.**—Camera will find a working drawing of a camera in No. 13 of Work. The size and principles involved are pretty well the same in all cameras, the difference being in the workmanship and finish bestowed. In reality, a camera is neither more nor less than a collapsible box with a lens at one end and an arrangement for holding the plates at the other, so that the lens and plate may be approached or separated from each other at will. Why not get one of the numerous handbooks on photography already published? Your suggestion shall be considered.—D.

**Carpenters' Bench Maker.**—J. O. H. (*Wandsworth Common*).—The address of a man who makes all classes of benches, and whose business is an old-established one, is: Mr. Hollis, 286, Old Street, Shoreditch, E.C.—J. S.

**Telescope.**—G. C. B. (*Echuca, Victoria*).—Mr. Clarkson, 28, Bartlett's Buildings, Holborn Viaduct, London, deals in second-hand telescopes. It does not appear that he publishes a catalogue of instruments on hand, as these must, of necessity, be continually varying in character and quantity; but I cull the following particulars from a memorandum sent me in reply to a letter addressed to him on your behalf. From this I find he has a 6 in. object glass by Wray, partly mounted, can be completed for £50; a 4 in. on hand at £20; also has knowledge of a 5 in., owned by a gentleman, who wants £55 for it. These are refractors. In reflecting telescopes, he has an 8½ in. equatorial at £20, which cost £60 from Mr. Calver, and a 12½ in. reflecting equatorial at £55, priced in Browning's catalogue at £248. Eye-pieces or powers are 15s. each. Of course, any or all of these are liable to be sold ere this meets your eye; but the above will serve, in some measure, to indicate the probable outlay necessary for the purchase of an instrument such as you require. Meanwhile, I would suggest that in future communications full particulars should be given as to mounting, powers required, etc., also (seeing that you only give aperture and focus) whether a refractor or reflector is intended, as you will observe there is a very substantial difference in price between the two types.—T. R.

**Arc Lamp for Alternating Current.**—W. T. (*London, N.*).—The makers of the Brockie Pell, the Crompton, and the Brush arc lamps adapt their lamps to suit alternating currents. Either or all of these are good lamps. If you wish to know anything respecting the behaviour of these lamps, write to Messrs. Crompton, Chelmsford, Essex, on matters relating to the Crompton lamp, or to Messrs. Woodhouse & Rawson, United, Limited, 88, Queen Victoria Street, London, E.C., who are agents for the sale of a large variety of lamps.—G. E. B.

**Price of Covered Wires.**—J. B. (*Bradford*).—Nos. 18 and 20 d.-c.-c. copper wire command a price varying from 2s. 4d. to 2s. 9d. per lb. It can be obtained from any dealer in dynamos and electrical goods. Wire-makers do not care to supply small quantities of wire to amateurs at any price, and dealers must be paid for their trouble in getting the wire from the makers.—G. E. B.

**Electro-plating.**—J. G. (*Liverpool*).—A short series of articles on "Electro-gilding and Electro-plating" such small articles as those which fall to the lot of watchmakers and jewellers to deal with, were published in WORK of April 4th and 25th and May 5th, 1891. The "Electro-platers' Handbook," price 3s., has been highly commended by practical men, who say it is the best book for amateurs and beginners in the art of electro-plating. It is published by Messrs. Whittaker & Co., 2, White Hart Street, Paternoster Square, London, E.C.—G. E. B.

**Brass Ferrules for Fishing-rods.**—W. S. (*Pontefract*).—Messrs. T. C. Hughes & Son, fishing-tackle manufacturers, Redditch, will supply these *wholesale*. Your better plan will be to order them through some local dealer in fishing-tackle.—S. W.

**Wood-pulp Paper.**—H. D. (*West Norwood*).—Messrs. J. Spicer & Son, importers of foreign papers, 120, Edmund Street, Birmingham, might be applied to. They have a reputation for supplying these foreign papers on lower terms than the London houses.—S. W.

**Harvest Festival Decorations.**—A SUBSCRIBER.—In decorating for a harvest festival, the idea is a grateful acknowledgment of the Divine blessing on the labours of man. The fitness of things, therefore, seems to demand that the first and most important place should be given to such of the food products of the earth as can be used with decorative effect, and that next to these should come cultivated flowers, also a result of man's industry under the Divine blessing; but that wild flowers, the spontaneous gift of nature, should only be used sparingly, as being less appropriate to the occasion. This would be my view of the case, but the subject is not one on which to be dogmatic. A SUBSCRIBER should read the articles on "Temporary Decorations for the Interiors of Buildings" in WORK, Vol. II., pp. 510 and 552, in which harvest decoration has been dealt with.—A. Y.

**Paper Wheels.**—W. H. K. (*No Address*).—The so-called paper wheels are of iron for tire, flange, and hub. The intervening space between hub and tire is so formed as to retain a composition similar in some of its constituents to paper, but not actually paper as we generally regard it, being a composition of tough, fibrous pulp, said to be forty-four parts of pulp, to which is mixed one part of starch, one of gum, one of bichromate of potash, and three of benzine. Linseed oil and glue also form part of the composition, which is forced into the wheel between the hub and tire by hydraulic power, and the pressure kept on till the material is set. This composition has been found to yield at the hub, and allow it to get loose before the wheel is worn down, so that the composition must be renewed or the wheel cast aside as useless. It is found to be essential that some form of radiating spoke attachment to the hub is necessary to ensure long life to such a wheel, which, after all, has the composition in the most non-essential part of it. Wood is used to fill in the space sometimes, but that does not constitute it a wooden wheel.—J. C. K.

**Distance Register.**—KILOMÉTRIQUE.—The municipality of Paris, which determines the traffic management of Paris streets, and the regulation of hired vehicles traversing the city, are now trying

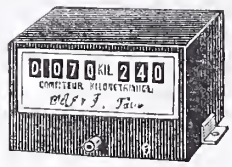

Fig. 1

Fig. 2

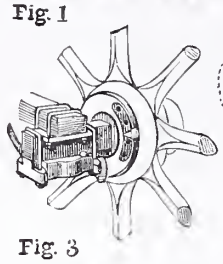

Fig. 3

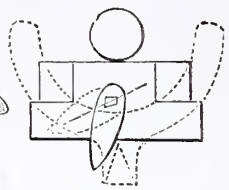

Fig. 4

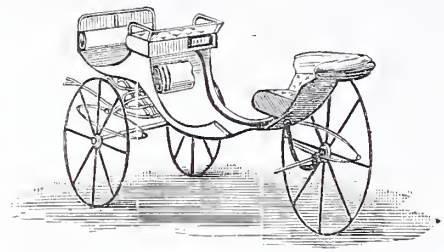

Fig. 5

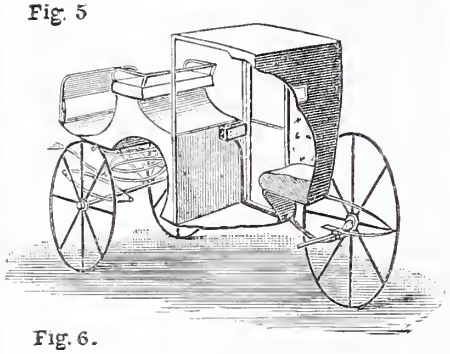

Fig. 6.

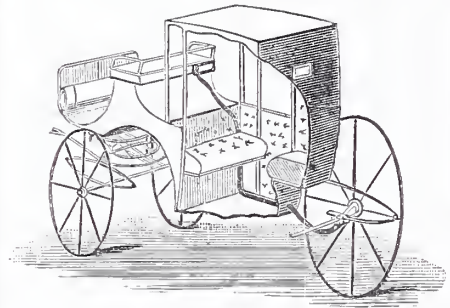

Fig. 7.

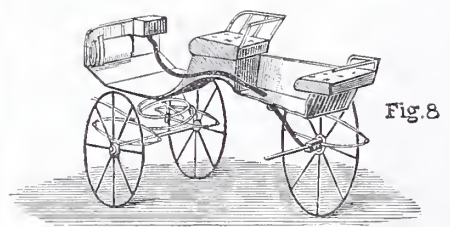

Fig. 8

Fig. 1.—Register of "Compteur Kilométrique." Fig. 2.—Wedge on Nave. Fig. 3.—Mode of applying Wedge. Figs. 4, 5, 6, 7, and 8.—Sketches showing Modes of fitting Register on Vehicles of different kinds and forms.

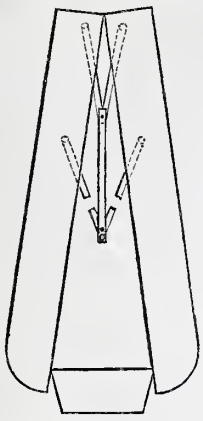
several competing systems of "distance registers," and at the beginning of the new year will report on them, and if one is more efficacious than others, will probably authorise its adoption by the Paris cab companies, so that the law of compulsion to use them is irrevocable till the municipality chooses to rescind or alter it. Amongst several registers now on trial, or are patented with the view to ulterior adoption, some indicate fare to be paid, as well as distance travelled; some the time occupied on a journey, and for parcels, register the weight carried, etc. Amongst the many is a distance register known as "Compteur Kilométrique," by Boiquand et Fils, 127, Rue Oberkampf, Paris. It is simple in form, and follows nearly, in its constructive application, most wheel-operating mechanism for the same object. The register is contained in a small box, about 4 in. by 4 in. by 5 in., with the statement of distance on the front, as shown by diagram, Fig. 1. Its action is pneumatic in its motor of transmission. This is fixed on the inside front rail of a single brougham, just under the rail of the glass-rest known as the "belt-rail" in the trade. (Fig. 6.) For an open vehicle it is fixed at the back of the coachman's seat; for a double brougham the same position is best, being out of the way of the backs of the front-seat riders; also for Victorias. For a phæton the dash-iron is used to attach the register to, as is shown severally by Figs. 7, 5, and 8. The plan of attachments, of course, varies with the vehicle, but the main device is by screwed clips, holding a box of transmission under the axle (as in Fig. 3), close to the back of the nave of one of the hind wheels of a four-wheeled vehicle, as shown by Fig. 4. A wedge (Fig. 2) is fixed on the back face of the nave, just inside the nave-hoop, as shown in Fig. 3. A pawl is struck by this wedge once in every revolution of the wheel: this acts in compressing the air in an indiarubber tube, which communicates its impulse to letters on the dial of a register forming the index. This tube is protected by a casing of copper pipe, carried from the axle inside the body under the lining up to the register.—J. C. K.

**Covers for WORK.**—J. H. (*Wolverhampton*).—The pasteboard covers were suggested as temporary means to keep the numbers clean until binding time comes. Your wish is that the advertisements could be relegated to covers, on the plea that as the numbers are now constituted the advertisement pages must of necessity be bound up with them. Otherwise, if they were cut away the front page of each number would be set adrift. There are more ways than one of killing pussy, and I have always found that if I am dead set on carrying out any laudable desire I can generally manage it in one way if not in another. You can cut away the 15th and 16th pages, leaving a narrow strip of paper to paste along the inner edge of page 14. This will secure the front page, and accomplish your purpose. Or you might annex a leaf, which would give you two blank pages for memoranda. Never mind the gaps in the pagination; there will be no reference to them in the index.

**Camera Obscura.**—BRIGHTON BIRD asks for the most simple way to construct a camera obscura 10 in. by 20 in.; also the way to make small paper balloons, material used, etc. If BRIGHTON BIRD has, or could procure, the fourth volume of *Cassell's Popular Educator* he would there find the subject treated more fully than can be done in "Shop." With reference to the camera, I presume it is 10 in. wide and 20 in. long. In one end a central hole must be cut to receive a focussing tube carrying a lens, which must have a focus a little more than the combined length and depth of the box. At the opposite end to the one carrying the lens, one-half of the top must be removed and replaced by ground glass, the rough side outside. A mirror is fixed in the box, slanting from the back at an angle of 45°. The light passes through the lens, and pictures the object on the mirror, which reflects it up to the ground glass. Under ordinary circumstances, the diffused light in the room would render the picture very faint; to prevent this, a hinged flap with side pieces is placed in front of the ground glass on the outside, which puts the picture in the shade, and thus allows the details to appear. The essentials are a lens with adjustable tube, mirror placed at an angle of 45°, and a ground glass plate to receive the picture; all else must be a matter of taste or cost. It may be said that there are many modifications of the instrument, but the one given is the simplest. *Balloons.*—I have made these toys, but not for many years. The material I employed, and what is generally used, was coloured tissue-paper. Decide the size of the balloon, and cut the gores accordingly. I fastened the pieces with gum. The making is a very simple affair, requiring more patience and gentle handling than anything else.—O. B.

**Re-charging Accumulators.**—W. J. D. (*Manchester*).—The plates which show white or milky patches have been discharged too much. The set of cells must never be discharged below a mean pressure of 2 volts per cell. If you fully discharge any of the cells, the plates will be ruined by the formation of lead sulphate. Test them when you think the charge is nearly run down, and re-charge any cell giving a less pressure than 1·9 volts. Sir David Salomons, in his book on the "Management of Accumulators," says:—"There must always remain about 25 per cent. of the total charge the cell is capable of taking, otherwise troubles arise." Did you re-charge the battery before you emptied the cells of acid? If not, you should have done so. You should also keep the cells charged when standing idle, by sending currents through them every day or two. The colour of the plates should be the same after re-charging as after the first charging. Your remedy now is to overcharge them with a reduced volume of current some few hours more than usual.—G. E. B.

**Parallel-acting Bench Vice.**—S. AFRICA.—The vice referred to is one that is in use, though but little known, and has acted properly with heavy work of carriage making, so that yours should do the same. I will help you to a comprehension of your difficulty, and explain the principle which determines the parallelism of the jaws under screw pressure with anything held tight at the upper parts. The diagram (Fig. 1) shows the jaws with a block of wood in, and the screw applied, with such excess strain put on it that the top parallel irons are rent apart. This would be the result if the joint-pins in the vice did not yield from their fixings. It is possible your joints spring, or are too loose, or the lower diagonal irons are a little short. To remedy any of these defects, have them a little longer than the upper ones, but they must be only so to a trifling degree, which will be compensated for by the slight free-play of the joints and fixings.—J. C. K.



Parallel-acting Bench Vice.

**Oil for Gas Engine.**—W. J. A. (*St. Helens*).—We use an oil specially made for Messrs. Crossley, the makers of the Otto gas engine. This is all that could be desired. Vegetable oils of a low flash point clog the piston and cylinder with carbon. Castor oil is unsuitable.—G. E. B.

**Heating of Dynamo Machine.**—W. J. A. (*St. Helens*).—If a shunt- or a compound-wound machine is run without a load—that is, unconnected to any work in the outer circuit—all the current generated in the armature coil is sent through the shunt coils on the field-magnet cores, and there is a consequent heating of the brushes, as evidenced by sparks from them where they touch the commutator. If the brushes are taken off from any machine, whether shunt, series, or compound wound, there will be no current passing through the coils, nor any heating of the machine from this cause. If your friends have observed a rise of temperature when the brushes have been taken off, this rise must be due to increased friction of the spindle on the bearings, consequent upon increased speed of the spindle. I cannot think of any other cause, and this would be insignificant in a well-made machine.—G. E. B.

**Engine without Valve or Eccentric.**—BONZO.—Oh, BONZO! how could you write to us on such a piece of paper! It surely comes out of the dust-bin. Yes; you can make a little oscillating engine, like those in the toy-shops, without either valve or eccentric. You will see a drawing of the parts, etc., of this in WORK for November 30, 1889, p. 589, Vol. I.—F. A. M.

**Monogram for Fretwork.**—T. W. C. (*Wolverhampton*).—I have drawn the T and C in outline to show that they are practically the same as the T

Monogram for Fretwork—T.W.C.

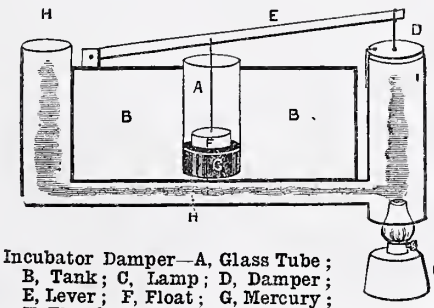
and G of the monogram T.M.G, appearing in No. 104, p. 813, and by sloping the sides and slightly rearranging the centre of the M, produced the W. If T. W. C.'s eye is sufficiently trained, and he possesses intelligence and patience enough to pierce an elaborate portrait frame, I should have thought him capable of making these trifling alterations himself.—A. C.

**Voltage of Dynamo.**—W. J. D. (*Manchester*).—Your dynamo is evidently a compound-wound machine. Consequently, when you are taking the full current of 35 amperes from the machine, this volume of current is passing through the field-magnet coils, and strongly magnetising the fields. If the normal speed of 920 revolutions per minute is maintained at this time, the voltage of the current will also rise, because the armature coils revolve in a more intense magnetic field and cut stronger lines of magnetic force than when the field-magnets were less strongly magnetised. I am not well acquainted with the machine named by you, so can only surmise the pins you mention to belong to a set of resistances restricting the output of the machine.—G. E. B.

**Candle-making and Tallow-refining.**—W. G. (*Bradford*).—I am unable to point out any book on this subject, but there are interesting and useful articles upon it in "Cassell's Household Guide," Vol. III., pp. 143 and 161.—M. M.

**Honey Extractor.**—S. L. (*Haslemere*).—If you procure Nos. 77 and 81 of WORK, you will find, at pp. 395 and 465, descriptions of the "Little Wonder" and "Cylinder" extractors. If you take up bee-keeping, I would strongly advise you to get Vol. II. of WORK, and read the papers on "Hives and other Apiarian Appliances" running through it. I shall be most happy to help you in any way.—APIS.

**Incubator Damper.**—R. T. (*Sunderland*).—The gas regulator does not work a damper, but the expansion of the mercury cuts off the supply of gas. Before R. T. will see this, he will have seen a section of Hearson's patent incubator, which does depend on the action of a damper for its efficiency, the temperature, when it rises above the desired point, causing the current of hot air from the lamp to pass straight away and not heat the tank of water. Any chemistry book will tell the boiling points of various fluids, but the special fluid used



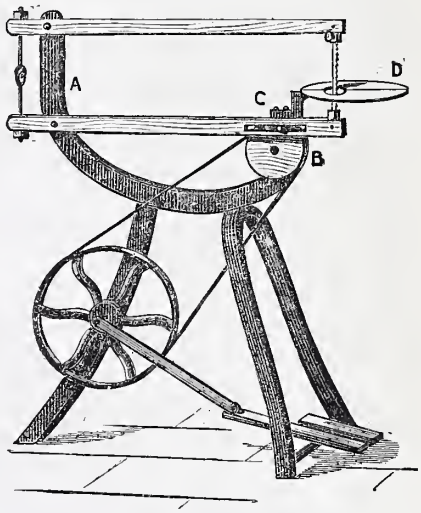
**Incubator Damper—A, Glass Tube; B, Tank; C, Lamp; D, Damper; E, Lever; F, Float; G, Mercury; H, Flue for heating Tank; I, To let off the Heat when Damper rises, which it does when Mercury expands.**

by Mr. Hearson is his discovery, and the vital part of his patent. R. T. can no doubt find other fluids to answer the same purpose, but I am not sure whether he may copy the invention of Mr. Hearson so closely. I think benzoline would come nearest the required temperature, but mercury might be used, according to enclosed sketch. Though I am always glad to help the readers of WORK, this is not a precedent to show that I can invent a scheme to assist everyone who is in a difficulty. It is not always possible.—B. A. B.

**Dark Slide.**—R. I. L. C. (*London, E.C.*).—The simplest plan is to get some good hard eight-sheet cardboard; cut a piece the same size as the focussing frame, glue some strips on to the face of it round the edges, so that a cell is formed in which the sensitive plate can be placed. On these strips glue others half the width, and again on these some wider ones, so that a groove is formed in which a piece of cardboard, to act as a shutter, can slide up and down. Cover the shutter with cotton velvet, and let it project ½ in. beyond the top of the rest part, so that it can be pulled out for exposure. The whole should be painted over with Bates' black varnish. In this manner a useful dark slide may be extemporised. Care, of course, must be taken to have the dimensions accurate to suit the camera, and so that the plate will occupy the same position as the ground glass of the focussing screen. Also the fitting of the cardboard must be good, so that all stray light is prevented from access to the plate. —D.

**Camera.**—QUÆSITOR.—(1) The camera and lens mentioned is a serviceable article, and very good work can be done with it. (2) Single portraits can be taken with these lenses; the drawback is that the exposure is somewhat long. The rapid rectilinear lens is better in two respects—absolutely straight lines are given, and the aperture of the slot is much larger, of course, working so much more rapidly. (3) Yes. (4) The price mentioned is low; consequently lenses by the best makers are not available, as they would exceed this figure. Only trying a lens will ensure that it is suitable for what you want, as the cheaper lenses vary very much in quality; very good ones may be had. Why not try Morley, Islington Green, or Sands and Hunter, Cranbourne Street, for a second-hand one? (5) Yes; but a short focus lens is most suitable for enlargement. A long focus lens requires a long distance between the lens and the focussing screen, which is sometimes inconvenient.—D.

**Fret-Machine Saw.**—HOMERTON.—With reference to my reply to you (see page 765, No. 99), the following illustration should have accompanied the text:—You will see that the arms are riveted to the framework (A). About an inch from the centre



Fret-Machine Saw.

of the wheel (B) a small pin is fixed, which works in a slot of the arm (C). There is a small grooved wheel fixed under the table (D) to steady the saw when running; perhaps that is where you have managed to get your idea that the saw is fastened to a wheel. —W. R. S.

**Luminous Flame Gas Stoves.**—W. P. (*Southport*).—You can obtain luminous flame gas stoves from almost any maker of gas-heating appliances. Try Messrs. Clark & Co., Park Street Works, Islington, N. I have been unable to trace the company you mention, but possibly you may obtain the information you require through the *Gas and Water Review*, published at 22, Buckingham Street, Adelphi, W.C. It will be sent post free for 3d.—T. W.

**Developer.**—STOP.—The developer may be obtained of Mr. G. W. Secretan, 210A, Tufnell Park Road, N., in bottles, 1s. and upwards. In compound lenses, the best position for the stop is midway between the front and back combinations. The nearer the stop is placed to the back combination, so much more is the area of illumination increased and the field made less flat. If the stop is nearer to the front combination, the area of illumination is reduced, with a corresponding increase in the

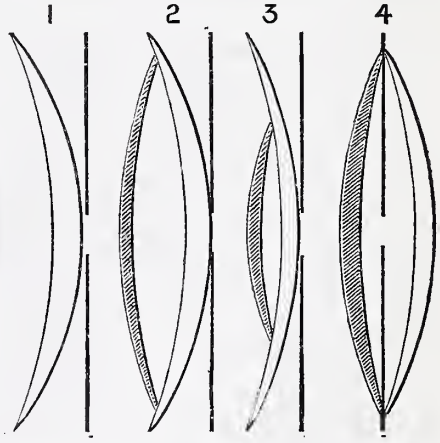


**Diagram showing Construction of Ordinary Spectacle Glasses for Photographic Work. No. 1.—Single Lens Long Focus; No. 2.—Medium Focus; No. 3.—Wide Angle or Short Focus; No. 4.—Medium Angle. The convection shown is greater than that usually found in Spectacles in order to show it more distinctly. The straight line shows the position of the Stops.**

flatness of the field; but in the case of portrait combinations the alteration is not very pronounced, and a spot midway between the two is generally chosen. When single lenses are used for portraiture or landscape, the stop should be placed in *front* of the lens, at such a distance that the area of illumination is just sufficiently large to avoid dark corners.—D.

### III.—Questions Submitted to Correspondents.

**Upholstery.**—A NEW SUBSCRIBER would like to know of any book on upholstery and decorative drapery. Also where it can be had, price, etc.

**Tuck Pointing.**—SLATER writes:—"Will any practical reader inform me, through the pages of 'Shop,' how tuck pointing is done? Also what materials and tools are required."

**Photo Sizes.**—J. A. MCL. (*Glasgow*) writes:—"I would be very thankful (should you consider them worthy of a place in 'Shop') if you would insert the following questions:—Would any reader supply me with a list of photo sizes—that is, after the photos are trimmed and mounted? My purpose is to have a list of those sizes to assist me in my work of cutting mounts; also how to prepare gold paper for edges, and bronze solution for line on mounts?"

**Cement.**—J. J. (*Ottawa, Canada*) would be glad to hear of a cement that would join the fancy ebonite handles of umbrellas when broken.

**Oil Engine.**—E. A. (*Ashford*) writes:—"I should be glad of readers' opinions upon this point. Many gas engines have one or more holes round the cylinder, which the piston, in its passage through the cylinder, alternately covers and exposes. These holes communicate in the Dugald Clerk engine with exhaust, and in the Maxim engine with supply, so obviating the necessity for further mechanism for exhaust or supply respectively. Is there any important condition to be observed in making such escape and supply parts—for example, must each piston ring, and each division between the rings, be broader than the holes so used as ports to prevent catching? And might such holes be made ¾ in. in diameter, the cylinder being 5 in. in internal diameter? Also would it be necessary to arrange that the split part of each ring should not pass over the holes?"

**Wicker Stains.**—A. B. (*Westminster, S.W.*) writes:—"I have a wicker chair as good as when I first had it, but the stain or brown colouring has rubbed off, and it looks bad. Will some reader kindly tell me how to colour it afresh?"

**Heating Room.**—C. J. P. (*Derby*) writes:—"I have a room about 8 ft. by 5 ft. by 9 ft. high, which I want to warm cheaply. Can it be done in some way with a box of lime? It is used as a study, and lighted by a duplex oil lamp. A stove of any kind would be disagreeable in such a small room."

**Tool Kits.**—JERRY will be thankful to anyone who will give him a guide to a handy kit of tools for use for odd jobs in carpentry, soldering, painting, glazing, and shoe repairs.

**Kites.**—H. N. (*Ipswich*) would be glad to know if any correspondent can inform him how to make ornamental flying kites representing birds, men, etc., or how kites of large proportion, equal to drawing small loads, can be made; and where books on the subject can be obtained.

### IV.—Questions Answered by Correspondents.

**Draughtsmanship.**—H. B. P. (*Hendon*) writes, in reply to NEMO (see Vol. II., page 686):—"In answer to above, the only book I know of is 'The Draughtsman's Handbook,' by André, published by E. & F. N. Spon."

**Coating for Damp Walls.**—THE AUTHOR OF "EVERY MAN HIS OWN MECHANIC" in reply to R. A. P.'s inquiry on this subject, wishes to call his attention to the following extract from the book named, which will afford a sufficient reply with regard to the proportions of the ingredients to be used:—"The writer has found nothing better or more effectual (as a coating for damp walls) than a solution of shellac and naphtha in the proportion of about four ounces of the former to a quart of the latter. This solution, when applied to the damp surface of the plaster, almost immediately hardens into a varnish impervious to water, and as soon as it is hard and dry the wall paper may be pasted to it. It gives a reddish colour to the wall, but this matters little, as it is covered over and hidden from view by the paper. The smell of the naphtha is most unpleasant; but, fortunately, this soon passes off, and the inconvenience falls chiefly to the share of the workman who applies the varnish."

**French Polishing.**—F. C. B. (*W. Brighton*) writes:—"Having noticed that T. A. (*Belfast*) asks for a preparation to prevent the oil coming through the polish, after polishing—put a rubber of patent glaze on; this is what I have used in the shop for years, and found it answered."

**Cylinder Marine Engine.**—C. J. W. (*Beccles*) writes as follows in reply to BON FIL:—"Let me advise BON FIL to send to J. Sutcliffe, Leek, Staffs., for his illustrated catalogue of model engines, castings, etc., price 3d., post free. 1½ in. bore and 1½ in. stroke would give him ample power. If he intends to have a twin-screw engine, ¾ by 1 in. would probably suit. He can get all parts with link motion reversing gear, either in rough or part finished, from J. S., who will also send him drawings of boiler supplies, instructions with castings, which are brass, and which I have found easy to fit, having made a nice-looking launch engine."

**Safes and Safe Locks.**—ONWARDS (*Nottingham*) writes, in reply to INQUIRER:—"I have been a subscriber to WORK from the first, and I like it very much. It is thoroughly practical. In a comparatively early number of WORK I notice that a correspondent (INQUIRER) is asking for advice about opening safes. The best way, if it is possible, is by picking them. If he will order a book called 'Lock Construction,' published by Crosby Lockwood (London), he will there find an apparatus invented by Mr. Hobbs, an American, who came to this country some time ago, and astonished Chubbs's by opening their lever locks. When there is a hard steel plate fixed behind the front plate I think they could be softened with a blowpipe or a Bunsen burner. And as to fitting a safe key to pattern, the way to do is to take the exact sizes with a pair of callipers."

**Ink Bottles.**—J. A. G. (*West Rainton*) writes, in reply to INK BOTTLE:—"Let him send to Kilner Bros., bottle manufacturers, Dewsbury, Yorks, for catalogue. I believe the size required by him costs a little over 2s. per gross."

**Frame for Wardian Case.**—J. T. (*Glasgow*) writes as follows in reply to W. P.:—"The frames or astragals for Wardian cases in wood are similar to window astragals for window frames with corner uprights, the glass being set in and bedded with putty. If you wish to set the glass without putty, prepare the wood for astragal without rebate for glass, and make a groove sufficient for thickness of glass to slip into, providing for the introduction of the glass by unscrewing the vase-shaped finials which have a double screw, the one half in finial, the other half in upright astragal."

**Furniture Polish Cleanser and Reviver.**—B. A. B. (*Hampstead*) writes, in reply to C. H. W. (*Hastings*):—"Without knowing the receipt C. H. W. is using it is difficult to advise, but revivers do not usually contain polish. D. A. has twice advised him to omit or reduce quantity of polish. He must omit it altogether if he fails with it, and he is sure to fail by using it for reviver."

**Banjo without Brackets.**—B. F. (*Birkenhead*) writes, in reply to ALPHA (*Birkenhead*):—"The patentee of this is in Conway Street, Birkenhead. The banjo can be seen in his window."

**Pitch of Roofs.**—DUMMY writes as follows, in answer to C. M.:—"I may say that one-third of the span is more generally used as the guide for the pitch of ordinary roofs, though it depends on what they have to carry, tiled roofs requiring a steeper pitch than slated ones, a square pitch being generally used. I have heard one-fourth span indicated in a technical school as being the best. Such a one on a large roof would require very strong timbers. For a lean-to roof, two-thirds span is generally used for the height of the pitch."

**Purchasing Timber.**—A. R. (*Scorrier*) writes as follows in reply to A. J. H.:—"I might say that I have been quite long enough in the trade to know that three 1 in. boards cannot be had from a 3 in. deal, no matter what the understanding may be; and that A. J. H. need not be surprised at my remarks on page 635, Vol. I. As A. J. H. was writing for the instruction of amateurs, it was folly to bring or try to bring them on a level with the professional before he gave them a clear explanation. Supposing the amateur wants the board to hold up ⅛, after he had worked it up and followed the advice of A. J. H., he would find that he had been misled, and that his supposed 1 in. board before it was worked could not have been more than ⅞. My motive in writing as I did was that that the amateur might have a clear understanding, and not to make him equal to the professional before he really was. I may add that at the time of writing my thinking cap was in its right place, and that I am not offended at the observations of A. J. H.; it is only giving light to those on whom the light should shine."

**Organ Building and Parts.**—AMATEUR ORGAN BUILDER writes:—"I see in WORK, No. 128, p. 382, that C. W. T. (*Old Trafford*) wishes information on organ building and organ pipe making. Now, if C. W. T. would call upon me, I may be able to assist him, as I am now building a small four-stop organ myself. I have enclosed you my address if C. W. T. would like to write you for the same."—[If C. W. T., or any other amateur organ builder, is wanting pipes, action, or any separate part of organ work, he cannot do better than apply to Mr. Beales, organ builder, of Limes Road, Croydon, who makes this part of his business a speciality, and has ample plant for turning out every detail in organ construction. His price list is clear and reasonable.—F. J. C.]

**Restoring Leather Chair Seats.**—A. J. (*Faversham*) writes, in reply to ANXIOUS (see p. 366, No. 127):—"If not worn in holes, these may be very satisfactorily restored with Jackson's varnish stains. I have used these several times with perfect satisfaction."

### V.—Brief Acknowledgments.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—S. & Co. (*London, E.C.*); C. F. (*Wellingboro*); J. M. (*Hastings*); P. A. C. (*London*); A. W. W. (*London*); F. W. (*Wernetli*); C. W. B. G. (*Birmingham*); G. P. (*Elgin*); W. S. (*Ilford*); T. R. (*Sheffield*); G. J. W. (*Antrim*); G. F. J. (*Oldham*); PLUSH FRAME; A COUNTRY LAD; IRIS; G. W. C. (*Loughton*); W. S. (*Northampton*); W. L. (*Huyton*); CYCLIST; W. L. (*Hull*); NESCIENCE; J. W. (*South Lambeth*); E. R. (*Battersea*); READER FROM THE FIRST; E. F. B. (*Liverpool*); J. A. G. (*Inverness*); DENNISTOWN; A NEW READER; F. S. (*Kidderminster*); H. L. (*Carlisle*); J. P. & SON (*Hebden Bridge*); T. R. B. # A WONDERFUL MEDICINE.

# BEECHAM'S PILLS

Are universally admitted to be worth a Guinea a Box for Bilious and Nervous Disorders, such as Wind and Pain in the Stomach, Sick Headache, Giddiness, Fulness and Swelling after Meals, Dizziness and Drowsiness, Cold Chills, Flushings of Heat, Loss of Appetite, Shortness of Breath, Costiveness, Scurvy and Blotches on the Skin, Disturbed Sleep, and all Nervous and Trembling Sensations, &c. &c. The first dose will give relief in twenty minutes. This is no fiction, for they have done it in countless cases. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

**Worth a Guinea a Box.**

FOR FEMALES THESE PILLS ARE

"A priceless boon, a treasure more than wealth; the banisher of pain, the key to health."

These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the nervous and debilitated is,

***BEECHAM'S PILLS have the Largest Sale of any Patent Medicine in the World.***

Prepared only by the Proprietor, T. BEECHAM, St. Helen's, Lancashire, in Boxes 9½d., 1s. 1½d., and 2s. 9d. each. Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*

## KING'S COLLEGE, LONDON.

EVENING LECTURES.

ARCHITECTURE AND BUILDING CONSTRUCTION AND QUANTITIES.

The first of the above Lectures will begin on Monday, October 5th, 1891, at the usual time—7 o'clock p.m.

The Subjects for this Term are—Foundations, Brickwork, Building Stones, Timber, its several forms, and Timber Construction in Roofs, etc., etc.

At the end of the academical year, Certificates, Money Prizes, Silver and Bronze Medals, will be awarded, provided the work is of sufficient merit.

For further information, apply to
Professor BANISTER FLETCHER,
29, New Bridge Street, E.C.; or
STANTON PRESTON, Esq.,
Carpenters' Hall, London Wall.

## KING'S COLLEGE, LONDON.

Wood Carving Classes have been established here by the Worshipful Company of Carpenters, in conjunction with the Council of the College.

Day Classes are held on Mondays, Wednesdays, and Fridays from 2 till 5; instructor, Mr. W. H. Howard, Secretary to the British Institute of Wood Carvers; and Evening Classes on Mondays and Wednesdays from 7 till 9; instructor, Mr. G. J. Bull, Member of the B.I.W.C. Fees per Term:—

| | | | | |
|---|---|---|---|---|
| 1 day per week | .. | .. | .. | 1 guinea. |
| 2 days per week | .. | .. | .. | 2 guineas. |
| 3 " " | .. | .. | .. | 2½ guineas. |
| 1 evening per week | .. | .. | .. | 10s. 6d. |
| 2 evenings " | .. | .. | .. | 18s. 6d. |

Students nominated by the Carpenters' Company are admitted at half-fees TO THE DAY CLASSES. Students are provided with tools free for their first Term, and prizes are offered by the Company every year, the sum of £23 having been thus awarded in July last.

Arrangements have been made by which ladies are permitted to attend. Next Term will commence on Monday, October 5th, 1891.

Further particulars may be obtained of the Carpenters' Company, London Wall, E.C.; or of the Secretary, King's College, Strand, W.C.

ESTABLISHED 1851.

## THE WINTER ELECTRICAL MACHINE AND ACCESSORY APPARATUS.

BY CHAS. A. PARKER.

PREFATORY—DESCRIPTION OF THE WINTER FRICTIONAL MACHINE—THE BASEBOARD AND SUPPORTING STANDARDS — THE PLATE-GLASS DISC—FITTING SPINDLE TO PLATE—ELECTRICAL CEMENT—THE HANDLE—THE RUBBER—THE RUBBER CUSHIONS—THE PRIME CONDUCTOR—THE COLLECTING RINGS—ADJUSTING SCREWS FOR BASEBOARD—THE SILK FLAP—MAKING THE WINTER RING—SUPPORTING FEET OF BASEBOARD.

THE science of electricity may be justly described as being one of the most sublime examples of the might of the human intellect, for by its agency man has brought a power subservient to his will which plays an important part throughout nature, and whose applications are now to be found in almost every branch of science. "*Nil mortalibus arduum est*," wrote Horace in speaking of Prometheus, of mythological fame, who is said to have stolen the fire from heaven; and it may be rightly said that the truth of this assertion has been repeatedly proved by modern science, although the writer of the passage could little have thought how near becoming verified would be the fable of Prometheus in after ages.

This subtle agent which we call electricity would appear to be uniformly diffused throughout nature, existing in almost every substance without giving any outward indication of its presence until called into existence either by mechanical, chemical, or physical action, when it is capable of producing effects that are as wonderful as they are startling.

During the present century electrical knowledge has progressed with rapid strides, and scientists have striven their utmost to subdue and apply this subtle power to domestic and commercial purposes, with the result that it has now become a most valuable helpmeet of man; the development of this branch of physics having resulted in such inventions as the electric telegraph, the electro-motor, electric light, electric railway, etc., and doubtless, as time goes on, we shall witness its still further development.

In the present series of articles it is the writer's intention to describe the construction of an electrical machine and accessory appliances, such as would be used by the student when studying that branch of electrical science known as frictional electricity, which, by the way, is always particularly fascinating to the experimentalist.

For obvious reasons it will be impossible to enter upon the theoretical or experimental portion of the subject in the present series of papers, as it would be out of place in this publication. I shall therefore confine myself to the practical construction of the apparatus necessary for the performance of experiments such as are described in the text-books devoted to the subject of frictional electricity.

The plate electrical machine may be said to be the most popular form of frictional machine ever introduced, as it affords a ready means of generating electricity for the experimental purposes of the student or science teacher; and of all the various modifications and improvements in plate machines which have from time to time been devised, the addition of the Winter ring must claim attention as being one of the most useful.

In construction, the machine about to be described may be said to consist of a glass or ebonite plate mounted between a couple of upright standards attached to a substantial wooden base. The rubber holder, which is mounted on a glass stem attached to an adjustable wooden foot, occupies a position on the baseboard about midway between the two standards, and is made in the form of a U, through which the plate passes as it revolves. A couple of flat pieces of wood furnished with felt pads and brass springs are pushed into the rubber holder, one on either side of the plate, against which they are forced by the pressure of the springs, a slight projecting ledge at the back serving to retain them in position whilst the machine is being worked. A double wing of thin silk is attached to the rubbers and curved in the form of the plate, to which it adheres by electrical attraction, thus serving as a means of conveying the electricity to the collecting rings of the prime conductor. The latter consists of a hollow brass ball mounted on a glass support attached to an adjustable wooden foot similar to the rubber, the side of the conductor next to the plate being fitted with a projecting arm and a couple of wooden collecting rings which are furnished with a row of metal spikes or pins on their inner faces, arranged in such a manner as to almost touch the plate on either side; the outer side of the conductor having a brass ball and stem from which to suspend the apparatus. The Winter condensing ring, which is the most important part of the entire machine, is made to fit into a hole in the top of the prime conductor, and consists of a hoop of stout iron rod let into a highly polished ring of wood, an attachment of this description enhancing the power of the machine about threefold. In the writer's estimation, this machine is undoubtedly one of the most perfect, useful, and convenient forms of frictional machines ever devised.

Turning now to the constructive details, we come first of all to the baseboard and supporting standards for the plate, which are illustrated in Figs. 2 and 3. For the first named we shall require a piece of thoroughly well-seasoned mahogany, measuring about 12 in. by 20 in., and about 1 in. or 1½ in. thick. The importance of employing thoroughly well-seasoned wood cannot be too strongly impressed upon the reader.

When the board has been sawn to the required size, it will be necessary to round off the four corners by means of a panel saw, after which the sides and edges should be dressed up and shot by the aid of a plane until they are perfectly square and true with the face.

When this has been done, the baseboard may be placed aside for a short time whilst a couple more pieces sawn from the same board are being dressed up in a similar manner to form the two supporting standards for the plate. Each of these should measure when finished 15 in. long and 4½ in. wide at the lower end, tapering to 3 in. at the top, the lower end of each standard being sawn to the form of a dovetail, as shown in Fig. 3, which will then allow of its being securely fitted on to the baseboard. A pencil line drawn across the surface of the baseboard at 6½ in. from one end of the board, as shown by the dotted line in Fig. 2, will indicate the position for the first cut of the mortise to receive these dovetails, which are now cut to the required form by means of a saw and chisel. Before proceeding further, a hole about ¾ in. diameter should be bored through the upper end of each standard, at exactly one inch from the rounded end of the wood, in order to form the bearings for the spindle of the plate; and when this has been done one of the standards should be provided with a movable wedge, fitted just above the hole, in order to make suitable provision for the removal of the plate. This may be done by making a couple of saw-cuts from the rounded end of the wood down to the aforesaid hole, thus forming a slot, each side of which will now require to be cut to a sharp bevel. A small block of wood of suitable size is now grooved along opposite sides in the form of a V by means of a saw and chisel, and then made to slide tightly along the slot just formed, as will be seen by reference to Fig. 4. If considered necessary, a hole of sufficient diameter to take a pin, about the size of an ordinary blanket pin, may be bored through the standard and into the wedge, for the purpose of retaining the latter in position during the working of the machine.

As soon as the two standards have been prepared, it will be advisable to mark the position for the mortises on opposite sides of the baseboard into which the lower dovetails of the standards are to be fitted; cutting each of these mortises by the aid of a saw and chisel, and afterwards attaching each one in turn to the baseboard by means of a couple of 2 in. brass screws and some good glue.

Now that the wooden framework of the machine has been described, it behoves us to turn our attention to the glass plate, and the manner in which it is to be mounted between the two standards. For this size machine we shall require a 12 in. circular disc of good plate-glass, provided with a ¾ in. hole in the centre through which to insert the spindle upon which it turns. It will be necessary to procure this from an electrician, as the size, shape, and thickness render it impossible for an amateur to cut and prepare a glass plate of this description. The usual charge for a plate of these dimensions will be found to range from 8s. 6d. to 10s. 6d. It may not be out of place to draw attention to the possibility of getting a plate from a clock-glass manufacturer at prices considerably lower than the above: for example, Mr. Jude, watch, clock, and barometer glass manufacturer, of Clerkenwell, would supply a glass disc according to the above description for 4s. 6d.—carriage, of course, being extra, as this is the price of the disc.

Having secured a suitable glass disc, we shall next require a 12 in. length of ¾ in. glass rod to form the spindle upon which the plate may turn: this can be readily obtained from any electrician at 1s. per lb. The rod must first be roughened at either end, also in the middle, in order that it may take the cement properly, after which a couple of bosses, about 1¾ in. diameter, should be turned from a piece of sound dry hard wood, and then made to fit tightly on to the spindle. One of the bosses should now be cemented in the middle of the rod by the aid of a small quantity of cement, and when this has set quite firm, a little more should be brushed over the inner face of the boss, after which the glass disc is very carefully let on to the spindle while the cement is moist, being pressed into the closest possible contact. When this has been done, the other boss is treated with cement in a like manner and then lowered on to the other side of the plate, when the whole is placed aside out of harm's reach until thoroughly hardened. Cement used for this purpose can be readily made by melting in an old iron saucepan: resin six parts, beeswax one part, plaster of Paris half a part, with just a small quantity of turpentine. A tin saucepan is useless for the purpose, as the bottom would come out; it is therefore necessary to use an iron pot or a suitable ladle. Another cement which will answer just as well can be made by mixing together Le Page's fish glue with plaster of Paris until a thick paste is formed. As this cement is made without the aid of heat, it will be unnecessary for the glass to be warmed before it is applied.

On returning to the plate, the next proceeding will be to fit a couple of brass caps on to the ends of the spindle, and likewise provide it with a handle. The caps or mounts may be readily formed from a couple of gasfitters' straight brass nose-pieces, which should be about 1½ in. long, with an internal diameter of about ⅞ in., each one being furnished with a small hexagonal or round nut tapped to screw on to it. Before doing anything else, it will perhaps be advisable to prepare the handle. For the arm of this a piece of stout brass plate about ⅛ in. thick should be cut and filed to the shape of Fig. 5, care being taken to finish it off neat and smooth, with a small hole drilled through it at the taper end, as shown in the diagram. A brass nut belonging to one of the nose-pieces may now be taken, and soldered on to the broad end of the metal in the position indicated in Fig. 6; after which a small wooden sleeve of suitable size should be turned in a lathe to form the handle of the machine. This sleeve must of course be furnished with a longitudinal hole, into which the metal rod of the handle may be loosely fitted. This

rod should now be riveted and soldered into the hole at the narrow end of the handle crank, when the wooden sleeve just prepared may be slipped on to the rod, and then retained in its place by means of a small button riveted on to the outer end of the rod. It is almost needless to say that the sleeve of the handle must be arranged in such a manner as to revolve with perfect freedom.

At this stage of the proceedings the two nose-pieces should be cemented on to the ends of the spindle, and then the plate may be mounted in position between the two standards of the machine, in order to ascertain whether it is running quite true and with perfect freedom; and if so, the nut may be screwed on to the projecting portion of the nose-piece on one side of the machine, whilst the handle is screwed on to the opposite end of the spindle—as will be understood by reference to Fig. 7, which shows the sectional appearance of the plate and spindle. When the plate has been remounted in a satisfactory manner, and is found to be running quite smooth and true, it will be time to turn our attention to the preparation of the prime conductor and the rubber, commencing with the latter, which is illustrated in Fig. 8. The rubber holder, shown at A, may be made from a single block of wood, measuring 5 in. by 2½ in., with the two sides tapering from 3 in. at the base to 2½ in. at the top, the rectangular slit to contain the rubber cushions being readily formed by first making a couple of parallel saw-cuts for 4 in. longitudinally down the block, and then removing the wood between the saw-cuts by the aid of a keen-edged mortise chisel, after which the sides are carefully smoothed off, and a narrow ledge glued on to the top of each side, as will be seen by reference to A, Fig. 8, and to Fig. 9. A 4½ in. length of ¾ in. glass rod (B, Fig. 8) is now cemented into a hole of sufficient size, bored for its reception in the under-part of the rubber holder by means of a suitable centre-bit, the other end of the glass rod being cemented into a turned wooden socket, similar in appearance to C, Fig. 8. This socket need not be turned according to any exact dimensions, but should be made proportionate to the remainder of the rubber holder. It should be furnished with a ¾ in. projecting pin at the bottom, which must be glued into a hole bored in one end of a small slotted foot, cut to the form of D, Fig. 8, which is drawn in plan in Fig. 10. This foot may measure about 4 in. long, 1½ in. or 2 in. wide, and 1 in. thick, being sawn from a piece of sound baywood by means of a fret or panel saw, and when carefully cleaned up it may be glued on to the lower wooden socket of the rubber holder, which is now completed, with the exception of a pair of cushions.

These cushions may be made from a piece of ⅜ in. mahogany, which is planed down to about ¼ in. thick in such a manner as to leave a slight ledge projecting along one side, as will be seen in Fig. 11. This arrangement will prevent them from being carried through the holder by the motion of the plate. A piece of spring brass, about ½ in. wide and 3 in. long, will require to be riveted to the middle of the outer side of the wood, in order that the cushion may be pressed against the plate with a uniform pressure, after which the rubbers are completed by gluing a piece of thick soft felt on to the outer side or face of each one, in the manner indicated in Fig. 11; the rubbers when in place occupying the position indicated in Fig. 9, which is a side view of the rubber holder.

The rubber being finished, we must next turn our attention to the prime conductor, which is illustrated in Fig. 12. This consists of a large brass ball, mounted upon an insulating glass stem, cemented into a suitable turned wooden foot, similar to the rubber. The ball has three openings for the attachment of apparatus—one at the top, to take the stem of the Winter ring, and the other two in the centre, upon opposite sides. For this large ball the writer can recommend a large brass knob, such as will be found upon good-class bedsteads, one of which will answer this purpose very well. The ball should be about 4 in. in diameter, and must be provided with two ¼ in. holes in the centre of the body, and a ⅜ in. opening exactly at the top, as may be understood by reference to Fig. 12. Two lengths of brass tubing must now be inserted, and soldered into each of these openings, in the position shown in Fig. 12: one piece of stout tubing, 9 in. in length, being soldered crosswise through the centre of the ball from one opening to the other, with about 2½ in. projecting on either side; the second piece, which is of much larger diameter, being put through the opening in the top of the ball, and soldered flush with the surface. A fair-sized brass ball is to be soldered to one end of the small projecting tube, and the collecting rings, about to be described, are attached in a like manner to the other end.

To make these collecting rings, turn in a lathe a pair of half round wooden rings, about 3 in. in diameter and ¾ in. in width, using for the purpose a piece of sound dry mahogany, the surface of which is rounded on the outside, and left quite plain on the inside, as shown in section in Fig. 13. A couple of flat brass rings, ⅜ in. wide, with an outside diameter of 2⅝ in., are now turned from a stout piece of metal, and are then made to fit into grooves prepared for their reception in the flat sides of the wooden rings, being sunk slightly below the surface of the latter, as shown in section in Fig. 14. About twenty small holes should now be drilled at equal distances apart round each of the metal rings, into which a corresponding number of small brass nails or pins, about ¼ in. long, can be riveted and soldered in the manner shown in Fig. 15, thus forming the comb of the conductor by which the electricity is collected from the plate. When this has been done, the two metal rings are joined together (with the pins inside) by means of a short bar of brass rod, which is of sufficient length to allow of the glass plate of the machine just passing between the pins of the rings without touching (*see* Fig. 15). This bar must be riveted into holes drilled for its reception in each ring, and after the collecting rings thus joined together have been soldered to the projecting rod of the prime conductor, the outer wooden casing may be cemented on to each ring.

At this stage of the proceedings a 13 in. length of ¾ in. glass rod should be cemented into the large opening at the top of the conductor, in the manner shown in Fig. 12.

Assuming one of these bedstead knobs to be employed for the conductor, it will be provided with a slight projecting stem, which will be found very useful for the subsequent attachment of the Winter ring, the stem of which should be furnished with a corresponding tap, to enable it to be screwed into the stem.

A mahogany socket must now be turned in a lathe to the form of A, Fig. 12, and then cemented on to the lower end of the glass stem of the conductor, the projecting pin with which the socket should be provided being glued into an adjustable slotted foot similar to the rubber before described.

A couple of brass wing-nuts, and screws, about 2½ in. long, should now be let into the baseboard from the underneath, being planted one at about 7½ in. from the front end, and the other at 8½ in. from the back. The exact position should, however, be ascertained by trial. They must, of course, occupy the central line of the baseboard, and the heads of each nut should be let into the underside of the wood, just flush with the surface, being afterwards cemented in position by means of the ordinary electrical cement, or a mixture of plaster of Paris and glue.

The rubber and the conductor may now be clamped in position upon the baseboard, in order to be certain that the plate runs perfectly true, and everything is satisfactory, as it should be. As soon as this has been ascertained, a curved silk flap (Fig. 16) must be prepared and affixed to the rubber, to serve as a means of conveying the electricity to the conductor. The exact length of the silk required may be marked upon a piece of brown paper, which is held in position against the plate whilst the rubber and conductor are in their place. The silk should be arranged so as to reach from the outer edge of the rubber to within about half an inch of the collecting rings of the prime conductor, the width being the same as the height of the rubbers. From the template thus obtained it will be an easy matter to cut a couple of duplicates in thin black sarcenet, allowing just a trifle more than the exact plan to allow for turning in when sewing them together. A portion of the covering of a disused silk umbrella will be found to answer this purpose very well, provided that it is not slit or damaged in any way. As soon as the pieces of silk have been cut they must be carefully machined together along the curved side, after which the flap thus formed is glued on to the outer sides of the rubber, with the machined portion turned inwards next to the plate. Thus prepared, the electrical attraction will cause the flap to adhere to the plate upon the handle of the machine being turned. Only the semi-eircular curve of the silk is to be stitched, as the remaining portion of the silk simply requires to be cleanly cut by means of a pair of scissors.

As before stated, the Winter ring, which forms the attachment of the prime conductor, consists of a stout iron ring enclosed in a polished wooden casing, which should equal the diameter of the plate of the machine, in order to obtain the best results. It naturally follows, therefore, that the construction of a ring of this description will be a trifle beyond the capabilities of the average amateur, owing to the necessity for using a large-size lathe in which to turn the wooden ring. Nevertheless, as there may be some who would be in a position to make the attempt, I will describe the mode of procedure.

For a ring suitable for the machine under description, a sufficient length of moderately stout soft iron rod, about the thickness of an ordinary cedar pencil, must be bent into the form of a 12 in. ring, having a short projecting stem about 3 in. in length, similar in appearance to Fig. 17. The stem should now be tapped, in order that it may

be screwed into the opening in the top of the prime conductor, after which it must be provided with a stout casing of thoroughly dry wood. To make this ring, a couple of accurately planed boards, of a uniform size and thickness, should be mounted upon the face-plate of a lathe, for each one to be furnished with a groove of a sufficient depth to take half the thickness of the iron ring, which is made to fit into these grooves in such a manner that the two surfaces of the wood can be closed over the ring and glued together. After the grooves have been cut, each ring is in turn detached from the board, and the two are glued together securely, with the grain of the wood crossing, and the metal ring between them, after which, when the glue has thoroughly set, the outside of the ring is carefully rounded off and smoothed with glass-paper.

A small, neat, pear-shaped boss must now be turned in a lathe and fitted on to the ring, just at its junction with the stem. This boss must of course be made in two halves, and furnished with a couple of grooves crossing the flat surface of the wood in the form of a T, the shorter groove of which should be of a suitable form and depth to admit that portion of the ring where it forms the junction with the stem.

Those of my readers who do not wish to have the trouble of making the Winter ring themselves can obtain a 12 in. ring ready prepared, and with the outer casing highly polished, at 8s. 6d., from Messrs. King, Mendham & Co., a firm resident in Bristol.

At this stage of the proceedings nothing remains to be done but to turn four ornamental supporting feet, similar in design to Fig. 18, and then glue and screw one of these at each corner of the base, after which the entire wood-work of the machine may be varnished or French polished, according to the taste of the maker. Those who are unable to French polish will do well to use a hard-drying ebony enamel: such, for instance, as is to be found in the cheap black enamel varnish supplied by Messrs. Palmer & Co., St. Luke's, London.

## HOW TO MAKE A WASH-TUB.

BY H. HINGE.

INTRODUCTION—QUALITY OF WOOD—SIZE, ETC.—CUTTING OUT WOOD — MAKING — PUTTING TOGETHER—FINISHING.

AMONG the many articles which amateur wood-workers make, perhaps there is none which will please the "guid wife" better than a wash-tub (Fig. 1), which, if properly made, will last a lifetime, and, besides having many other advantages over earthenware pans, it cannot get broken.

*Quality of Wood.*—As the tub has to hold water—or, in other words, be water-tight—the wood must be as sound and good as we can get it, either white or red deal—¾ in. or 1 in. thick will answer the purpose very well, if it is free from dead knots and shakes.

*Size, etc.*—We shall find a convenient size to make for use about 2 ft. 4 in. long, 15 in. wide on the top, and 9 in. deep.

*Cutting out Wood, etc.*—As the tub is on the taper all ways, the best way to cut out our wood from the board will be as shown in Fig. 2. A considerable saving of wood is effected in this way. A "bevel" would be a very useful tool to get the right angle to cut and true the ends up with, but if we have not got one, we can manage very well without. Square up a piece of thin deal or cardboard, 12 in. or 14 in. long and 9 in. broad, and then take it 2½ in. less on the bottom edge. We shall then have a templet, 2½ in. out of square, to which we must work all our ends.

*Making, etc.*—After truing up the sides and ends correctly to "templet," and in pairs of the same size, we must take the sides and mark up from the ends with a gauge a line 1 in. clear from the edge, and all four ends of the two sides must be marked with this gauge, and then another gauge-line run up parallel with the first at a distance from the first line of the thickness of the stuff at the thinnest place. This is for the grooves to receive the ends; and, as the ends must fit in tight, we had better have them a little too small than too large. These must now be grooved out to a depth of

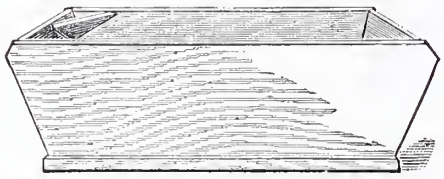

Fig. 1.—Wash-tub complete.

Fig. 2.—Diagram showing how to cut Sides and Ends from Single Board.

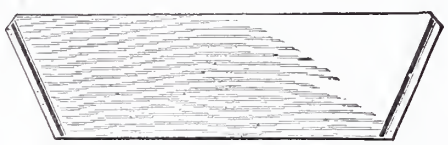

Fig. 3.—Side grooved to receive Ends.

about ¼ in., cutting down with a tenon-saw and cleaning out with a small chisel, taking care to get the grooves of an equal depth all the way through. The sides will then have the appearance of Fig. 3. By placing the sides and ends together, as they will be when together (not putting the ends in the grooves), it will be seen that the ends of the ends will want to be on the bevel a little to make a close joint. A shaving or two taken off with a sharp plane, where wanted, will remedy this, so that when the tub is put together all joints will be true and close. The ends must now be taken to a thickness on the ends, to fit in tight in the grooves, taking just the sharp edge off on the inside and planing away any surplus wood on the outside; but be sure and have them fit nice and tight (not too tight).

*Putting Together, etc.*—We shall now require some white-lead, which should be put in the grooves with a putty-knife or chisel—not too much, but covering the wood all over. The tub should now be nailed together with 1½ in. or 2 in. nails, put in about 2 in. apart. A fine 1½ in. screw, put in at each top corner instead of a nail, will make a much better job. The bottom edge of the tub should now be levelled off as true as possible, and then with a very dull iron chisel or the wrong end of a hammer, and using another hammer to strike with, bruise down a groove round the middle of the bottom edge; fill this groove with white lead, also a thin coat on the rest part of the bottom edge. The bottom should now be planed up true (we shall find a board 11 in. wide to be the right breadth without jointing), and nailed firmly down, taking care that none of the nails split or point out. A much better job is made by screwing the bottom down with fine 1½ in. or 2 in. screws. All surplus white-lead should now be cleaned off, and all interstices filled up with the same. We should now turn our attention to the top edge, and clean this off as nicely as possible with a sharp plane, cutting off the corners as in Fig. 1, and taking off all sharp edges with sand-paper. Two pieces of 1½ in. square stuff should now be screwed on from the inside to form handles on the ends. These will be much better if hollowed out a little on the underside (before screwing on) to catch hold of. We must now fit a piece in the corner to hold the soap, which should fit nicely, but not go down to the corner by ¾ of an inch, to allow the soap to drain. This should be nailed in from the outside. All nails and screws should be punched and screwed below the surface, and filled up with putty mixed with white-lead. The tub is now complete, and should be allowed to stand a few days before using to allow the white-lead to harden. The durability and appearance of the tub will be greatly increased by giving it a few coats of paint inside and out; but, of course, this must be left to the taste of the worker.

If the inside of the wash-tub is not painted—and there will be some, I dare say, who will think it unnecessary to do this—the joints of sides, ends, and bottom should receive a good coating of white or red lead.

## KNOTTING, SPLICING, AND WORKING CORDAGE.

BY LAUNCELOT L. HASLOPE.

### FANCY KNOTS.

WALL KNOTS—STOPPER KNOTS—MASONS' WHIPPING—CROWNING—MANROPE KNOTS—DOUBLE WALL KNOT, SINGLE CROWNED—TACK KNOT—MATTHEW WALKER—SINGLE DIAMOND—DOUBLE DIAMOND—SHROUD KNOT—FRENCH SHROUD KNOT—SPRITSAIL SHEET KNOT—BUOY ROPE KNOT—TURK'S HEAD.

WE come now to a perfectly different style of knot which, though they are termed fancy knots, are not necessarily used for ornamental purposes, but are often of considerable benefit; indeed, we could hardly do without some of them aboard ship. One of the most commonly used knot of this group is the "Wall Knot." Fig. 82 shows the knot ready for hauling taut. First unlay the strands at the end of a rope and make a bight with one strand, A; hold this to the standing part with the thumb of the left hand, then make a loop with the next strand, B, round the end of the first strand, and bring the remaining strand, C, round the end of the strand B and through the bight of A.

If the ends are taken round once more and brought up in the centre of the knot, it is called a "Stopper Knot." In this case the ends are whipped together and cut off level. How the "Wall Knot" acquired its name was always a puzzle to me until I once happened to meet with directions in a very old book on rigging, for making a basket which was

have "a small walnut knot crowned the end." A fancied resemblance to a alnut no doubt gave it its name originally, hich, for euphony's sake, was contracted wall knot.

Fig. 83 is the "Stopper Knot" finished. g. 84 shows the crowning commenced. pen the strands of a rope as before, but do ot put a seizing round the rope. Lay the rand A down over the centre of the rope, d bring strand B down over A and strand C er B and through the bight of A. Fig. 85 ows how the strands tie when they are In this case, after crowning as above, pass one end over the next strand in the standing part, and under the following one. Do the same to each of the other strands in succession. This may be repeated and the ends cut off. Masons, whose ropes have to stand a good deal of knocking about, generally use this plan; for this reason it is called "Masons' Whipping." Though very strong and standing hard usage well, this is not the neatest way of finishing the ends of a rope. Crowning may also be used in connection with other knots. For crown. A double-walled double-crowned, called a "Tack Knot," is made as the last knot—that is, double-walled and single-crowned. Now lay the ends by the sides of those in the single crown, and with the aid of a pricker bring them down through the double walling and they will be alongside the standing part of the rope. The knot is shown completed, with the ends cut off, in Fig. 88.

A Matthew Walker (Fig. 89) gives the knot open ready for being hauled taut. How this knot came by its curious name I

early taut. The strands in Fig. 84 are ardly in the position which they occupy hen the knot is actually being made, as ey are then much snugger; but to show early their relative positions I was com-elled to draw them as they appear in the gure. In criticising the illustrations, and of ese knots in particular, I hope my readers ill take into consideration the extreme ifficulty of making them so as to show with ny clearness the method by which the sult was arrived at. Making a knot is ne thing: showing on paper the method of aking it is quite another. Crowning may e used by itself as a method of preventing ie strands of a rope unlaying while in use. instance, we may crown first and wall afterwards, as shown in Figs. 86 and 87. Fig. 86 shows the crowning in the centre of the knot hauled taut; this is made on the end of a rope as just described. We now make a single "Wall Knot" under the crowning. When the knot is tightened it will appear as in Fig. 87, and is called a "Manrope Knot." A single "Wall Knot" may be crowned after it is made; we then have a single wall and a single crown. If now we wall again by passing one end under the part of the first walling next to it and bring it up through the same bight, and do the same with the other two strands, the result is a knot with a double wall and a single believe is not known. I learnt it some forty years ago, and the captain, an elderly man, who taught me, had known it all his nautical life, so I think we may take it that its origin is lost in the mists of antiquity. After putting a seizing round the rope and unlaying the end as before, bring one strand, A, round the rope and put it through its own bight, the next strand, B, underneath, through the bight of A and through its own bight, and the last strand, C, underneath, through both the other bights, and lastly through its own bight. Fig. 90 is the knot completed. The "Diamond Knot" is an ornamental knot made some distance from the end of a rope; it is therefore necessary

to unlay the rope considerably more than is required for the preceding knots. To form a diamond, bring each of the three strands down alongside the standing part of the rope, thus forming three bights, and hold them thus with the left hand. Take the first strand, A (Fig. 91), and putting it over the next, B, bring it up through the bight of the third strand, C. Take the end of the second strand over the third and up through the bight of the first. The last strand is brought over the first and up through the bight of the second. Haul taut and lay the rope up again. Fig. 91 is the way the knot is begun, showing the manner of taking the first strand. Fig. 92 shows the loops in their places with the ends through them before they are hauled taut. Fig. 93 gives the knot finished. This is a difficult knot to illustrate and describe; but the key to the knot is to remember that, after the bights are formed down the standing part, each end successively goes over the strand next to it and up through the loop beyond. This knot is the "Single Diamond." For a "Double Diamond" (Fig. 94) we make a "Single Diamond," as above, without laying up the strands; the ends are then made to follow the lead of the single knot through two single bights, the ends coming out on the top of the knot. The last strand passes through two double bights. When the ends are hauled taut they are laid up as before. The last four knots are used for the ends of lanyards, man and ridge ropes, yoke lines, etc.

The "Shroud Knot" (Fig. 95) is a very valuable knot for joining two ropes together; it is used for joining a stay or shroud that has been carried away. The ends of each rope are unlaid, and they are then placed within one another as in splicing, the parts not unlaid being brought closely together. Make a "Wall Knot" with the strands of one rope round the standing part of the other rope; turn the ropes over, and do the same with the other set of ends, and they will appear as in the figure. Open the strands, and taper and serve them over if you wish to make a particularly neat job of the work. Two ropes of different sizes may be twisted in this way, and will be quite secure.

"French Shroud Knot." In making this knot, unlay the ends and place the two ropes with the strands intermixed as before; bring one set of ends back on their own rope, and make a single "Wall Knot" with the other set of strands round the bights of the first set and the standing part. They can then be tapered and served as in an ordinary "Shroud Knot."

"Spritsail Sheet Knot." Unlay the two ends of a rope and bring the two sets of strands together side by side; these have to be walled together in precisely the same manner as a common "Wall Knot." A bight is made with the first strand, the second is put over the first, the third over the second, the fourth over the third, the fifth over the fourth, the sixth over the fifth and through the bight of the first; they are then hauled taut. It may be crowned by laying two of the strands along the top of the knot and passing the other strands alternately over and under these two, and afterwards hauling them taut. It may be double-walled after crowning by putting the strands successively under the bights on the left of them and through the same bights, and the ends will then come up in the right position to be crowned again. This is done by following the lead of the first crowning and putting the ends through the walling as before.

"Buoy Rope Knot." This can only be made on a cable-laid rope. Unlay the main strands, and take out one of the smaller strands, of which they are composed, from each of the large strands, and then lay them up again. The small strands that have been taken out are now single and double-walled round the rope, and then laid along the divisions after the manner of weaving, and their thin ends stopped with spun-yarn. A stop should be put round the rope with the spun-yarn where the knot is to be made before it is commenced, and the walling should be made right-handed.

"Turk's Head" is a highly ornamental knot of quite a different character to the preceding ones, inasmuch as, instead of being made out of the rope itself, it is formed on the rope with a piece of small stuff worked round it. A "Clove Hitch" is first made on the rope (Fig. 96); this must be slack enough to allow of the extra strands which will form part of it. Put part A over strand B, thus twisting the two strands; pass the end C under and up through the bight that B now forms, then twist again by putting B over A and run the end under and up through the bight of A. Continue twisting the strands by alternately putting one over the other, and at each twist bring the end under and up through the bight which is underneath, A at the commencement going over B; the bight which B makes will be the under one, and therefore the one through which the end C must be passed. The end C must be very much longer than shown as the whole knot is made with this part, and as the knot when finished contains three groups of three strands each, it is obvious that the length of cord used must be more than nine times the circumference of the rope round which the knot is made. Having made a sufficient number of twists (the number depends on the size of the knot), lay the end C, with which you have been working, alongside D, where it comes out of the knot, and continue following its lead through all its turns as it goes through the knot until you come round to the commencement again. There will now be a "Turk's Head" of two parts. If the end is again passed through by the side of the same strand as before, a complete "Turk's Head" of three parts will be formed. Care must be taken to keep the strand with which we are working close to and on the same side of the strand we are following, or a perfect knot cannot be formed. The first time round is the most difficult, the second is easy enough. Of course, the knot may consist of more parts if required, but three are the usual number. Fig. 97 gives the finished knot. The ends do not require fastening in any way, as in the last round they finish in the middle of the knot under the coils, and are quite secure.

## A SADDLER'S CLAMP.

BY OPIFEX.

CLAMP NECESSARY—MATERIALS—CONSTRUCTION—STAVES—LOWER PIECE—PUTTING TOGETHER.

OF all amateur workers, the amateur saddler is most easily furnished with "a kit": a ball of hemp, a lump of cobbler's wax, a few needles, and an awl. With the aid of these and a bit of leather many odd jobs may be done; and if the "stitch in time" be seen to, not only will the proverbial "nine" be saved, but many a broken bone as well.

But although an odd job may be *done* with the appliances mentioned, it cannot be *well* done with these alone, and no good mend, etc., can be accomplished without the assistance of the article illustrated in Fig 1, which I have called "a clamp," but am not certain whether it should be styled a "*pair* of clamps," or, indeed, clamp at all, for in my country it is called a "clams." But "what's in a name?" The chief thing is to have it and know its use; and therefore deprecating the scorn of those who possess the article, or a better, I address myself to any of my readers who may desire to possess it, describing in as few words as possible how I made mine many years ago.

*Materials.*—The parts A and B (Fig. 1) are made from two oak barrel-staves—in my case part of an old sugar hogshead—but the staves of a petroleum cask will suit admirably, and I believe the old sugar hogshead is a thing of the past.

Should neither of these, however, be available, some friendly cooper may be found who will, for a small consideration, supply a couple of suitable staves.

The lower portion,

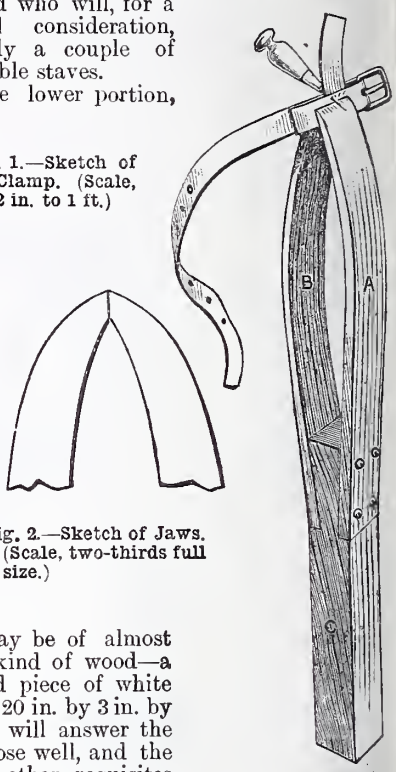

Fig. 1.—Sketch of Clamp. (Scale, 2 in. to 1 ft.)

Fig. 2.—Sketch of Jaws. (Scale, two-thirds full size.)

C, may be of almost any kind of wood—a sound piece of white deal, 20 in. by 3 in. by 3 in., will answer the purpose well, and the only other requisites will be eight stout 2¼ in. screws.

*Construction.*—Having selected two sound staves, they should be cut 2 ft. long by at least 3 in. wide, the points of greatest convexity being in the centre. And here I may mention that the more bent the staves are the more useful will the clamp be.

Clean up the outside with a spokeshave, leaving one end the full thickness of the staves, or about an inch, and thinning off gradually to about ¾ in. towards the upper ends, which are to form the jaws of the clamp. Round off the outer corners in their full length, bearing in mind that the clamp is firmly grasped between the legs when in use, and clean up the inside surface flat, smoothing both sides with glass-paper.

We now turn our attention to the lower part, C.

The dovetail-shaped tenon, which should be at least 6 in. in length, will require careful cutting, the depth of the shoulders and also the width of the upper end depending upon the amount of curve in the staves which are to be attached to it: but if the worker bears in mind that his object is to firmly embed the staves so that their upper ends, or the jaws of the tool, shall press

tightly together, no difficulty will be encountered.

With this object the tenon should be cut, so that energetic screwing will be required to bring the staves home into their final position.

The positions of the screws, which should be countersunk flush with the surface of the staves, are indicated in the drawing, and Fig. 2 (two-thirds size) shows the shape of the jaws.

## OVAL AND CYLINDRICAL VESSELS IN SHEET METAL WORK.

BY R. ALEXANDER.

WATER POTS—BOILER FILLERS AND TOILET CANS (*continued*)—HOW TO CUT OUT, MAKE AND FIT THE TOPS AND SMALL WORK, SPOUTS, ROSES, ETC.

*The Tops.*—Boiler fillers and water-pot tops are both made in the same manner. To make the pattern, Fig. 1, set the compasses to such a radius as will give a circle about $\frac{3}{8}$ larger all round than the outside of the wire of the tops.

Describe a circle, and from any part of its circumference, A, with the same radius describe the arc, B C. This is the geometrical pattern, but as is very often the case with patterns geometrically true, there has to be a little allowance made for hollowing up. It is found in hollowing up that the points B and C draw up, and if no extra allowance were made the top would be too small, or it would have to be pressed down very much at that part and would look "squatty," so a gentle curve can be drawn as shown by the dotted lines—about $\frac{3}{8}$ of an inch each side at the widest part will be sufficient. Allowance must also be made of $\frac{3}{8}$ inch inside the curve, B C (also shown by dotted lines), for wiring; notches must also be cut across the points B and C as shown. The tops are hollowed much the same as a saucepan cover, which they practically are, with a segment cut out; the large block hammer must be freely used along the cut-out part or it will pucker very much; they will be found rather more difficult to hollow than saucepan covers, but a little practice will overcome any difficulty that may be experienced. Crease the tops for wiring in a swage or on the crease iron with a creasing hammer, and wire with a small wire on the edge of the crease iron. I generally use a hammer for putting the wires in these tops, and after wiring, hammer the wiring through the same crease that the tops were creased in, using a rounding faced hammer. Swage or crease round the other part to fit the wiring of the bodies, and fit on. Take care to get the points of the top equidistant from the seams by making marks with the compasses the proper distances from each seam, and setting the points of the tops to them. Tack the top in three or four places and solder round.

*Tops of Toilet and Hot-water Cans.*—These are flat with a hinged cover; the top will require a little explanation. When wired and fitted to the can it covers somewhat more than half of the can (*see* Fig. 2). Mark out first a facsimile of the bottom pattern, draw a line across the middle, A B, and two inches from that draw a second line and cut across. The reason so much has to be allowed beyond the centre is because the bosses (shown by the shaded parts on line A B) will come $\frac{1}{2}$ to $\frac{5}{8}$ in. beyond the centre, and $1\frac{1}{4}$ in. has to be allowed for wiring and turning back, which I will now describe.

The top being cut out as Fig. 3, cut four slits at distances shown, and 1 in. in length (these $\frac{3}{4}$ wide pieces can, when wired, form the hinges); fold the edge and wire, sink the wire and make a mark with the compasses $\frac{1}{4}$ in. to $\frac{3}{8}$ in. clear of the wire, and double back on the hatchet and flatten down on the crease iron. Hold the tops in the vice, and, with a small file, file the $\frac{3}{4}$ pieces till they part from the top; they will then work on the wire and may be used as hinges, or they may be taken out and longer pieces put in, which is usually the case in best work where the covers are riveted on. Another way of forming the hinges is to notch the covers (Fig. 4), and make the hinges on them, and rivet or solder to the top. Fold the edge over to fit the cans; this is done partly with the jenny, and partly with the half-moon stake, and requires care.

The covers must next be made if they are to be riveted on, as that cannot be done after the tops are soldered on. It is not a hard matter to cut out a pattern for the covers. Place a top on a can temporarily and measure the distance between the wire and the edge of the can, as from X to X, Fig. 2. Mark out a top from the pattern you have and take a section of it, allowing $\frac{1}{2}$ in. more than the measure just alluded to, and about $\frac{1}{2}$ round the D part; this will allow for wiring. Cut a cover out by this, wire it all round and see how it fits, and correct pattern accordingly. The wire in the covers is sunk by running it through the jenny; tack the covers to the tops and rivet. The tops and covers can then be fitted to the cans. The handles can next be made and fitted. The back handles have already been mentioned, and I will now describe the cross handles. A good rule for the length to cut them is to take half the circumference of the body; thus, if two singles were used for the body, the handles would require to be cut the length of a single plate (14 in.). As to width, six out of a plate will do for water pots, and a little narrower for toilet cans; cut them the shape shown (Fig. 5); then cut off a good notch of the right shape, which is important, especially for toilet cans. Fig. 6 shows a full-size end of a cross handle, with A, a properly cut notch, and B, an improperly cut one. Anyone can see that when folded and wired the notch B would be practically gone, whereas A would then have as much left as there shows of B before wiring. The reason a long notch is wanted is so that the ends of the handle can be creased like the example (Fig. 7), which also shows the proper shape of the handle. They are fitted with a boss in the centre before being fixed to the can. Fig. 8 is the flat pattern drawn with compasses set to the sweep of the handle in the centre, which is the same as the ends of can. The handles can then be tacked on and the side bosses soldered on. Fig. 9 is the flat pattern of them; they are bent on the extinguisher stake, and should be soldered on strongly, as they are the principal stays of the can. Water-pot handles are fixed in a different manner. Mark on the top the place for the handle, and with a sharp chisel cut a slot the width of the handle just in the crease of the top; slip the handle down an inch each side and solder. The ends of the handle should be bent towards the body of the can before being put through (*see* Fig. 10, which is a section of handle and body, showing more clearly the method of fixing). Two stays which are made by turning narrow strips of tin on a piece of $\frac{1}{4}$ rod in the crease iron are next put on. Each end is flattened so that the seam comes underneath, and is soldered to handle and can, as shown at S, Fig. 10. Boiler filler handles the same way, except flat topped ones, which are put on like toilet cans and with side bosses; some hollow topped ones have side bosses, but most have the ordinary stays. The next consideration is the spouts. Fig. 11 shows the flat pattern for toilet cans and fillers; the top part, B, will form the nozzle, the seam of the spout will be uppermost, and the seam of the nozzle underneath; a little more lap must be given to the seam than to the nozzle, or it will not be large enough. It is as well to make a pattern slightly larger than the one derived by cutting the spout pattern as shown.* A water-pot spout would simply be a continuation of Fig. 11, and cut plain across at the end.

*Bosses and Stays.*—Toilet cans and boiler fillers have a boss between the spout and body. Fig. 12 is the pattern for it; it is bent on the bick iron across the dotted line; the straight part goes to the body, and the bevelled side down the sides of the spout. Water pots have simply a bridge and two stays similar to those for the cross handles. The bridge is a slightly tapering piece of tin turned half round and soldered, about 1 in. below the top and reaching to the spout; the stays are fixed level with it.

*Position of Spouts.*—Spouts should be made and fixed so that the bottom part of the outlet in toilet cans and fillers is a little above the level of the top of the can body, so that the water will not run out when they are filled; water pots some inches longer.

*Water-pot Roses.*—The ordinary rose is made in three pieces—socket, funnel or cone, and front. Two flat patterns only need be made—viz., the cone and the socket. The size of the front when ascertained by experiment can be marked on the cone pattern. The socket will of course require to be exactly the same degree of taper that the spout is; it can therefore be marked out from the top portion of the spout, varying in length according to the size of the can. The larger end of the socket is notched for folding; it is not wired, but simply flattened down. Turn round on the bick iron and fit on to the spouts, and solder the seams; fit them so that they slip on the spout about half their length. Care must be taken to get both spouts and sockets quite round, or the water will come out very much where the socket fits on. To assist in gaining a good fit the sockets should not be made of too stiff a material. The cone pattern (Fig. 13) next demands our attention. A look at the pattern will show that it is a circle with a portion cut away. On how much is cut out depends the shape of it. If only a small portion out of a circle of, say, 5 in. diameter is cut away, it will be a very flat cone, and if a large portion, say half, it would be a higher cone, but lessened in diameter. I shall give in a future paper full instructions for setting out cones of all shapes, but for the present example a very simple rule will suffice. Set the compasses to a radius of 1 in. less than the diameter of the rose required, describe a circle, and divide it into six parts. Mark two of them out by drawing lines from 1 and 5 to the centre, set the compasses to two-thirds the diameter of the sockets, and describe another small circle; allow $\frac{1}{4}$ in. on one side

* The ends of the nozzles of toilet cans and boiler fillers are either wired or false wired.

for soldering, and cut out. This gives the correct shape for water-pot roses. If wanted more conical, set the compasses the full diameter of the front required and take half of the circle so described; but this is what we term funnel shape, as it is almost an invariable rule to cut funnels a semicircle. There are several ways of fitting the front of the roses to the cones; two of the most used methods are shown in section the cone, and cut out the fronts, allowing a little for hollowing. Before hollowing, describe concentric circles as a guide to punching the holes (Fig. 15); hollow up like a tea-kettle cover. Next punch the holes with a round-pointed bradawl on a piece of wood. This is for ordinary water pots. For water pots requiring roses with fine holes a very small punch is used and the holes flattened down; the fronts of these are usually of the top of the cone on the seam side; solder round the socket and up the seam of the cone and the article is completed, with the exception of studs on the bottom, of which it is usual to put three on water pots and four on toilet cans. I omitted to state, though it was hardly necessary, that small handles must be put on the covers of toilet cans.

There are other varieties of cans, as I

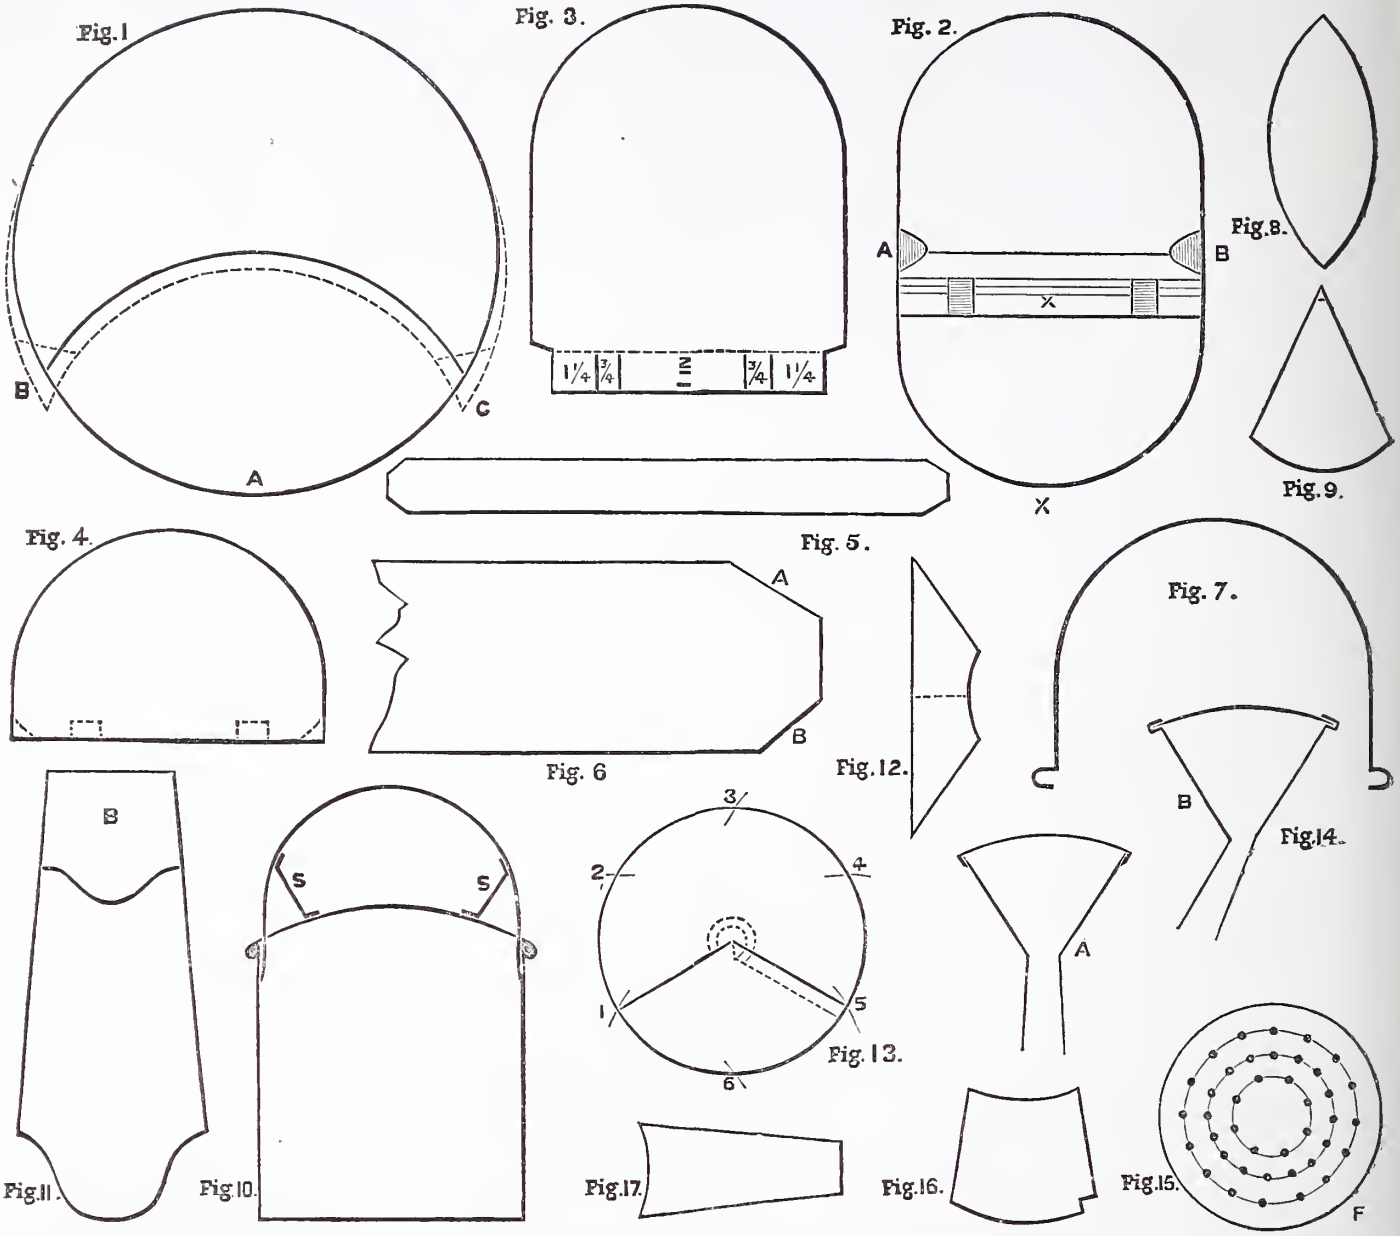

Fig. 1.—Pattern of Water Pot and Boiler Filler Top. Fig. 2.—Toilet and Hot-water Can Top. Fig. 3.—Details of Ditto. Fig. 4.—Toilet-can Cover. Fig. 5.—Cross Handle. Fig. 6.—Enlarged Section of Ditto, showing Notching, Correct (A) and Incorrect (B). Fig. 7.—Shape of Handle, showing Crease to fit Top. Fig. 8.—Boss Pattern. Fig. 9.—Side Boss Pattern. Fig. 10.—Section of Water Pot, showing Method of fixing Handle. Fig. 11.—Spout Pattern. Fig. 12.—Toilet-can Bridge. Fig. 13.—Cone Pattern of Rose of Water Pot. Fig. 14.—A and B, Sections of Roses. Fig. 15.—Rose Front, showing Holes. Fig. 16.—Pattern of Socket of Rose. Fig. 17.—Pattern of Bridge of Water Pot.

at Fig. 14, A and B. In method A the cone is soldered up and the front hollowed, pierced, and the edge "took up," slipped on, and soldered round. But the best and, I think, the most workmanlike way is method B, though it is a little more trouble. It is done as follows: instead of soldering the seam of cone all the way along, simply tack it with a dab of solder in the middle, and throw back an edge similar to the first edge thrown off on a saucepan cover (*see* article in Vol. II., page 661); then turn up a similar edge to lap over the front of the rose, measure across made of copper. Now untack the cones and slip the fronts in, and draw the cones together again and tack. If the fronts are too large they must be trimmed round. The edge is next flattened down by going round it on the half-moon stake with a hammer about twice; it need not be soldered round afterwards, except where the seam meets the front. The sockets can then be soldered in. They can be put in either upright, as A, Fig. 14, or at an angle, as B, Fig. 14, which is the most usual method. To allow this a little must be cut out before stated, but the reader will easily comprehend their make and shape on seeing them, and find that the instructions given for those that I have described will enable him to make them with very little difficulty. For instance, a strawberry pot is a very shallow can *without* a cross handle and with a very long spout, small at the end and without a rose. A beer can such as is taken out into the brickfields and hop gardens in Kent is made the same as a toilet can, with the exception that it is round instead of oval, and the spout is very small

at the nozzle. Thus each article described will show the intelligent workman how, by slight modification of pattern, etc., he can make other articles of a similar class, but differing slightly in detail.

I earnestly trust that the description I have given above, and in the preceding paper, of the method of dealing with oval and cylindrical vessels in sheet metal when making them will be intelligible to all who read it. That it will be so to the young professional reader I do not doubt, because it will be, if it is not so already, his every-day work, and he will have had opportunities of seeing it done by others, even if he has not done it himself. To such as these I hope my papers will be useful in showing them the why and the wherefore of the process to be followed in each stage of the making, from beginning to finish. If any amateur sheet metal worker finds anything that is not clear to him, I shall always be ready to help him through his difficulty in "Shop."

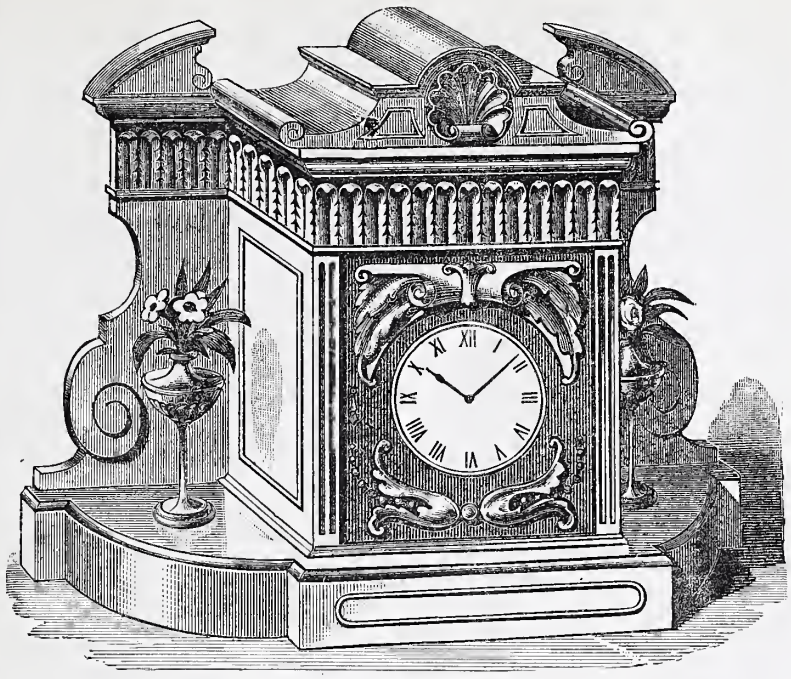

Fig. 1.—Perspective View of Case for Drum Clock.

## A CARVED CASE FOR A SMALL DRUM CLOCK.

DESIGNED BY F. FAULDING.

Remarks on Details—Front—Pediment—Plinth—Position of Clock—Clamping Door—Novelty of Design—Modifications of Design as given—Material and Ornamentation—Substitute for Pediments.

The accompanying design, exhibited in Fig. 1, is the perspective view of a carved case for a small drum clock. The details are shown on a somewhat larger scale in the remaining illustrations, of which Fig. 2 gives the carving for the front in which the drum is fitted, the half on the left-hand side of the centre line being shown; and in point of fact this is, or ought to be, sufficient for the wood carver, as the carving on the right-hand side is merely that on the left reversed. Fig. 3 supplies the details of the pediment placed on top of clock-case above the cornice, which is shown in Fig. 4. The plinth is shown in Fig. 5, and it will be noted that in this, as well as in Figs. 2, 3, 4, a section of the work is indicated. This is helpful in supplying a guide to the depth of the carving. The clock is placed in position in the circular opening cut in the front to receive it, through a small door attached to the case by hinges, and forming, indeed, the entire back of the case, framing excepted, which is formed by the case itself. The mode of carrying this out will be so obvious to anyone who is accustomed to do a little cabinet making, that it is unnecessary to go at length into the details of the construction. It will be sufficient to say that the back of the case should be flush with the outer surface of the door, and that the door itself should close against narrow strips placed within the case at sides, top, and bottom, at a distance from the edge of the opening exactly equal to the thickness of the door. If the workman be equal to the task, it will be better to clamp the door at the top and bottom, the grain running in a vertical direction, in order to prevent warping. If the door is not clamped, the better way will be to make it of two thicknesses of wood glued together, the grain of the outside piece running vertically and that of the inside piece horizontally. When made of a single thickness, even hard wood is apt to warp or buckle slightly, especially when the clock stands on a mantel-piece over the fire, and is thereby exposed to variations of temperature. When the door is made of a single thickness, the wood should be $\frac{3}{8}$ in. thick, but if of two thicknesses, each piece should be no more than $\frac{3}{16}$ in. thick.

Recurring for a moment to the design in Fig. 1, the novelty in it may be said to be the carved wings by which the case is flanked at the back, and the extension of the plinth in such a manner that it affords standing-room for two small glasses intended for the reception of single flowers, or, at the utmost, from two to four of the same kind, if not too large. Further, the plinth may be made sufficiently large to receive two tiny candlesticks, in the sockets of which may be placed two small petroleum lamps. This is frequently done now, lamps being made and sold for the purpose; and the effect produced is certainly pleasing, the candlestick and the lamp together forming a small pedestal lamp. The candlesticks may be of blue and white earthenware, silver, or brass; and if the maker of the case be a turner, he may make them of wood, or even of ivory if he cares to go to the expense.

The design may be carried out as drawn, or it may be modified in many particulars. For example, the wings and the extension of the plinth may be dispensed with, and the central part only be utilised as a case. Another modification may be effected by omitting the pediment above the cornice; but if this be done, it will be as well to make the top perfectly flat, so as to form a resting place for a small bronze figure. If this be done, it will be desirable to introduce another member in the form of a flat piece of wood with a moulded edge, between the top of the plinth and the bottom of the case proper of the clock; and, indeed, looking once more at the design in Fig. 1, it would be an improvement to add this feature, so that the ornamental vases, etc., at the side would stand on a lower

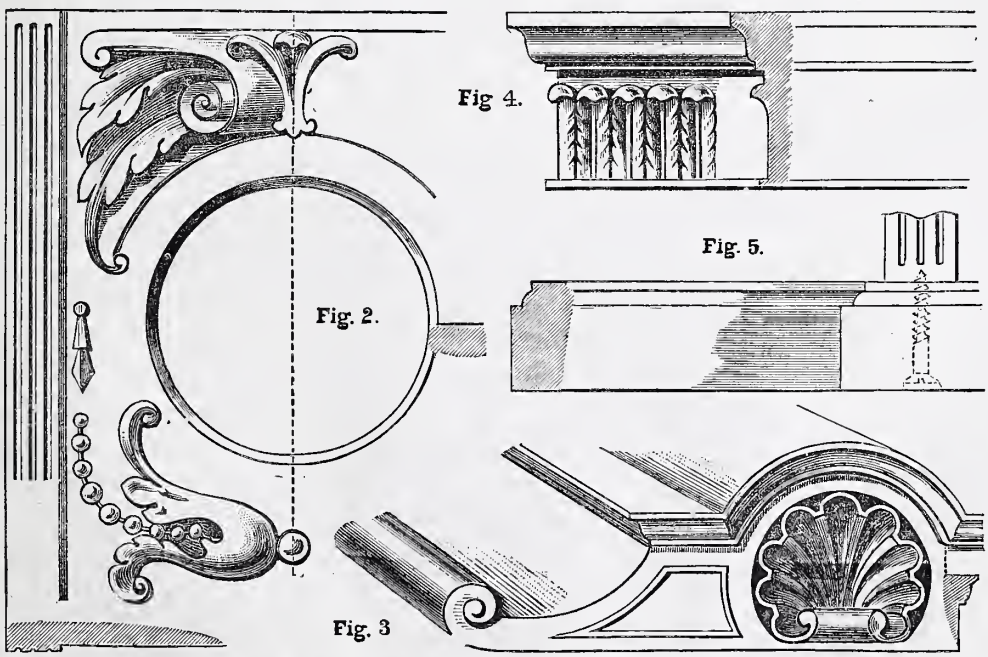

Fig. 2.—Details of Carving for Front, Left Side. Fig. 3.—Details of Pediment at Top of Clock-case. Fig. 4.—Enlarged View of Cornice at Top of Case. Fig. 5.—Plinth at Base of Case, showing Section.

level than the casing of the clock that is placed between them.

The material used may be walnut or any hard wood. If made in ebonised wood, with incised gold lines on the plinth, as shown in the design, and with the panels on the sides of the case defined in the same manner, a pleasing effect would be obtained. It may be suggested, too, that if the central case only were used, without the pediment, it would be as well to add a flat piece of wood on the top, with the edge moulded in the form of a quarter circle in section, and from ¼ in. to ½ in. less than the top of the clock-case on all sides, the back excepted.

## HOW TO SHARPEN A SCRAPER.

BY CHOPSTICK.

I AM often surprised to see a man taking a great deal of pains to plane up a cross-grained piece of wood, setting the plane as fine as possible, and turning the wood this way and that way; and after trying in vain to get a passable face on it, he tries first coarse glass-paper, then finer, until he does get a decent face on it—but by what a method? Decidedly amateurish, I think. Now, if that man would only use that very useful though simple tool, the scraper, he would do his work quicker and far better.

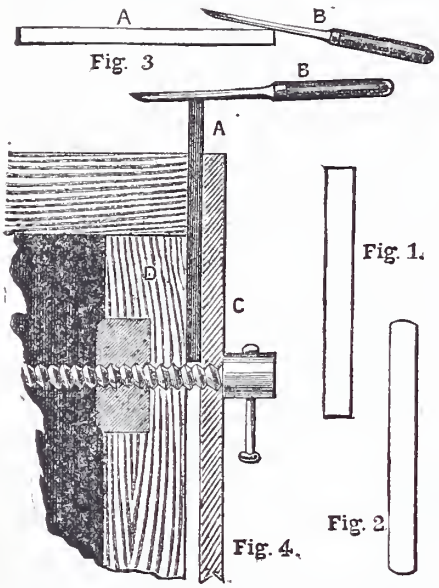

**Fig. 1.—Scraper properly filed. Fig. 2.—Scraper improperly filed. Fig. 3.—Scraper (A) and Gouge (B) in Position for Sharpening. Fig. 4.—Scraper in Vice for Finishing Touch. A, Scraper; B, Gouge; C, Vice; D, Bench. Drawings much exaggerated.**

In the first place, what is it? It is simply a piece of steel about 4 in. by 3 in.; a piece of saw-blade will make a good one, though the trouble of making would be more than it is worth, as they can be bought for 3d.

But now as to the proper way of sharpening it. First, screw it in your bench vice, edge up, and file the edge straight and square, being very particular to leave the corners sharp, as shown in Fig. 1, not rounded, as in Fig. 2. Then take a small gouge, and laying the scraper flat on the bench, rub the gouge (the back of it) to and fro along the flat of it, using as much pressure as can fairly be put on, and lubricating it with your spittle. Having done both sides like this, put it in the vice again the same as before, and taking gouge again, run it smoothly along the edge of the scraper with a hard, even pressure three or four times. You will then have two cutting edges, and if properly done you can take off shavings the whole width of the scraper and of a beautiful fine texture, leaving a splendid face on the most difficult working wood, which will only require a rub with the finest glass-paper to be ready for polishing.

In one shop where I was working a few months ago we made a great many first-class coffins, both oak and pitch pine, which all had to be French polished, and we scarcely used a smoothing-plane to any of them, simply taking out the saw-cuts with the jack-plane, and finishing with the scraper. Until that time I had been in the habit of planing, but I have altered my mind, and all the work I now do is finished with the scraper. One more word before I finish, and that is, do not attempt to scrape pine or deal, as it is too soft; but any hard wood it will do to perfection.

## OUR GUIDE TO GOOD THINGS.

*** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of* WORK *for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of* WORK *without charge, the notices given partake in no way of the nature of advertisements.*

### 68.—THE PERFECTED AUTOMATIC HAND CAMERA.

MESSRS. TALBOT & EAMER, manufacturers and dealers in all kinds of photographic apparatus, write to remind me that about eighteen months ago I noticed their Diamond camera in WORK, and that they have now "introduced a new camera, which has features not possessed, either together or separately, in any one of all the similar instruments in the market." Further, they enclose a few particulars and some specimens of its work, and express their willingness to forward fuller particulars. I would much rather that all inventors, patentees, and sellers who wish for a notice of their specialities in WORK would send a specimen of the camera or otherwise, as the case may be, for inspection. Publishers do not send particulars of their books when they wish for notices of them, but they send copies of the books themselves, and then the reviewer is able to judge of their value and how far the subject treated therein is handled in a suitable and useful manner. I cannot speak in positive and specific terms of any article unless I have had an opportunity of seeing it and handling it. As for the particulars and prices, they may be gathered from pages 4 and 5 of Messrs. Talbot and Eamer's "Price List of Photographic Apparatus," which, I presume, will be sent to any applicant who may choose to write for it. Further, it will undoubtedly be to the advantage of all persons who obtain mention of any speciality in WORK to keep that speciality well before the public by advertising in WORK. Many who receive notices are prone to say, "Yes, that's a very nice notice; that's just what I want. It gives publicity to my manufactured bantling, and it will save me the trouble and—well—expense of advertising." May I be permitted to remind my friends whose thoughts run in this direction that a notice is, in reality, but the insertion of the thin end of the wedge, and that it remains for those whose goods are noticed to drive it home by frequent advertising. Surely they must, one and all, be acquainted with the old saying, "Out of sight out of mind." The effect of any notice, be it as good as it may, is only ephemeral and evanescent, and its work is confined to little more than the week or month of issue. It is by regular and persistent advertising nowadays that a name or good repute for a speciality is gained and the support of the public secured. Here is a short story to the point, and very much to the purpose. I do not vouch for the truth of it, but I believe it to be perfectly true. A very well-known firm—I carefully abstain from mentioning names for obvious reasons—were accustomed, it is said, to spend as much as £10,000 per annum in advertising. Having done this for a long series of years, they were led to think that their name and specialities were as household words in every part of the inhabited and civilised world, and that they might as well lessen their outgoings by £10,000, under the idea that it would be useless to continue to spend so large a sum yearly in advertising. They did so, and the effect on their business was so marked that they were glad to spend as much as heretofore in advertising in the following year.

Let me say that it is not of the slightest benefit to me to cry up advertising, and add that I have only written as I have to explode the fallacy that when an individual or a firm has got a notice, he or they have got all they want, need, or require. I am simply telling the truth, the whole truth, and nothing but the truth, and I do it entirely on my own responsibility. I should have had much pleasure in giving an opinion of Messrs. Talbot & Eamer's Perfected Automatic Hand Camera if I had had an opportunity of examining it. Of the specimens of photos taken by its aid, which are now before me, I can only say that they are marvellously clear and distinct—so clear, in fact, that the features of persons in the middle distance are distinguishable. To judge from the photos themselves, the camera by whose instrumentality they were taken ought assuredly to be a good one.

### 69.—HOBDAY'S ILLUSTRATED CATALOGUE.

I have received from Mr. Henry A. Hobday, tool merchant, Chatham, a copy of his Illustrated Catalogue for 1891. As a list of the different kinds and sizes of tools on sale at his establishment, it will prove useful to all who obtain it. The cuts are clear and good—clearer, in fact, than those which appear in price lists usually are. It is well printed; the sheets are firmly held together by wire staples, and placed in a strong and neat gold-lettered cover. It is pierced at the upper left-hand corner, and a narrow tape is put through the hole, so that it may be readily hung up for reference in any workshop.

### 70.—"THE WOOD CARVER."

This is a new monthly publication issued by Messrs. Simpkin, Marshall, Hamilton, Kent and Co., Limited, at 1s. It contains full-size designs and working drawings for carved woodwork complete, with sections and description, selected and drawn by Mr. Henry K. Kuchemann. The designs, perhaps, may be regarded as fairly good, but there is nothing particularly striking in any of them, or calculated to excite particular admiration. The designs in Part I., for September, 1891, are a Renascence clock-case, a reading-desk, a bracket support, two cabinet photo frames, a two-leaf screen, a corner cupboard, and a friese pattern for hat-rail. But "Renaissance" is far more familiar and acceptable to the eye, at all events, than "Renascence," and more appropriate to the style of decoration that it is intended to describe; and I am not aware of any reliable authority for turning "frieze" into "friese." Yet, in common with the rest of mankind, I do not know everything, and there may be deeper depths in the etymology and rendering of these every-day words to which I am as yet a stranger. It is desirable that in all publications of this kind an attempt should be made to raise the designs that are given to the wood-carver, certainly above mediocrity, if it be not possible to render them unexceptionable. The great fault in those that are given in Part I. of *The Wood Carver* is that they are not graceful in conception, and when reproduced in wood are not likely to prove satisfactory, or in any way attractive. But possibly future parts may show an improvement in the direction indicated. Let us hope they may.

THE EDITOR.

# SHOP:

## A Corner for Those who Want to Talk It.

*** *In consequence of the great pressure upon the "Shop" columns of* WORK, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* WORK *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—Letters from Correspondents.

**Fret Machine.**—A. H. B. (*Belfast*) writes:—"There is only one fault I have to find with the fret machine described in answer to G. G. (*Abergavenny*) on p. 155, No. 114: and that is, it is too slow. Could J. H. W. give me a method by which I could gear it with fly-wheels to increase the speed?"

**Paste for Sharpening Razors.**—J. C. (*Belfast*) writes:—"I send the following, hoping you will insert it for the benefit of self-shavers. Take oxide of tin—in other words, prepared putty—1 oz., and a solution of oxalic acid in sufficient quantity to form a paste. This composition is to be rubbed over the strop, and when dry, a little water may be added. The oxalic acid having a great affinity for iron, a little friction with this powder gives a fine edge to the razor."

**Boiler Incrustation.**—INQUIRER writes:—"In WORK, p. 378, No. 128, you point out the want of a good incrustation preventer, and remark that a composition which will act in one place is frequently of no use in another—a result probably owing to the difference in the character of the water used. In Manchester the other day I came across a device which renders the use of so-called 'preventers' unnecessary. The Manchester Packing Company have had fitted an apparatus called the 'Gamgel Spouting Cowl,' and have been watching it for the past twelve months, with the result that they find it prevents incrustation absolutely, and—what is even of more importance—showed a saving of 13 per cent. in coal. I was not able to get a sight of the invention, but perhaps some of the readers of WORK can give us a description of it."

### II.—Questions Answered by Editor and Staff.

**Price's Lathe with Vertical Slide.**—G. H. (*St. Helens*).—R. Price's address is 125, Stratford Street, West Ham, E. The lathes will do turning, boring, milling, slotting, shaping, wheel-cutting. Ordinary lathes will do all these, but the vertical slide gives especial facilities for milling, boring, shaping, and wheel-cutting. For milling and boring with the bar, the vertical slide is so convenient, it is a wonder those who have no milling machine can be content to do without it. It is not pleasant to do much wood-turning on a lathe intended for metal, but if you wish to do this you might fit up wooden bars so as to continue the bed three or four feet, and take the poppet and hand-rest, but *not* the slide-rest, which you do not want for turning wood; it would only be in the way. Mr. Price says he has made one with a gap, so I suppose you can have one so if you wish. I think the watch lathe mandrel would not "jamb," but drive rather hard in drilling if made as you propose.—F. A. M.

**Pea-planting Machine.**—DEVON.—It can, I think, be easily done by fixing a cane on the axle of one pair of wheels—the cane, when in its highest position, to open a little trap-door in the bottom of a box. The door must open on the outside, otherwise it could not be closed against the peas. It should close smartly with a spring.—J.

**Oil Engines and Saw Benches.**—J. S. (*Beith*).—"Gas and Petroleum Engines," by Wm. Robinson, M.E., a practical treatise on the internal combustion engine (14s.). "Saw Mills," by M. Powis Bale (10s. 6d.). Nothing has appeared as yet in WORK on oil engines, and information is not as yet very easy to obtain.—F. A. M.

**Naphtha Engine.**—J. S. (*Pimlico*).—I believe Messrs. Yarrow are the makers of these engines, but they have not been perfected, and are still dangerous. I don't think anyone can tell you how to make one of these engines. The Priestman paraffin oil engine is, I believe, a success; and J. H. Knight, of Barfield, Farnham, also makes them. There is no oil engine at work that is not patented, to my knowledge.—F. A. M.

**Elementary Books on the Lathe.**—S. R. W. (*Saltburn-by-the-Sea*).—Why, certainly there are many suitable for an amateur; you will find them named in my papers on "Lathes and Turning Appliances," in Nos. 2, 4, 6, 8, 10, and 14 of the first Volume of WORK; and there, too, you will find such information as will enable you to choose for yourself the kind of lathe that will suit you best.—F. A. M.

**Speed of Drums, Pulleys, etc.**—AN INTERESTED READER OF "WORK."—Your inquiry is very vague. If you want to find the relative speeds of two drums geared together by a strap, or of two toothed wheels in gear together, you can get it from the fact that the numbers of their revolutions per minute will be inversely as their diameters; if one pulley or wheel is half the diameter of the other, it will make twice as many revolutions in a given time. If you want to calculate absolute speeds in connection with the transmission of power, the case is different. One horse-power is equal to 33,000 foot-pounds per minute. Suppose you want to transmit 20 horse-power from a drum 6 ft. in diameter, moving at 100 revolutions per minute, the circumference of the drum is $6 \times 3\frac{1}{2} = 18\frac{6}{7}$ ft., and the speed of the belt, therefore, $18\frac{6}{7} \times 100$ revolutions $= 1{,}886$ ft. per minute (nearly). The work of 20 horse-power is $33{,}000 \times 20 = 660{,}000$ foot-pounds; therefore the tension on the belt will be $660{,}000 \div 1886 = 350$ lbs. (nearly). If the power is transmitted by a toothed driving wheel, there will be this pressure on each tooth. If the hand tension is given, the necessary speed is found by dividing the work by it. Any of the standard text-books on millwork will instruct you in this matter; Rankine's is very complete, but it is expensive, and, perhaps, more mathematical than you may desire.—F. C.

**Platelayers.**—T. A. (*Bootle*).—This question is one of interest to boiler makers and engineers, as well as platelayers. The problem is one often dealt with in the shops, and I shall, therefore, answer it at length, without mathematics. First, you have a curve, A (Fig. 1), of 396 ft. 5 in. radius. Taking a chord line, B, of 10 ft. in length, you want to know the height of the rise, E, from the chord to the curve. E is termed the "versed sine," D, D are "semi-chords." To get the height of E, it is necessary to square the radius of the curve A, and also of the length, D; subtract the latter from the former, and take the square root of the remainder; then

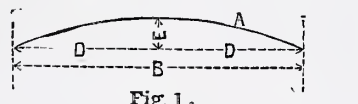

Fig. 1.

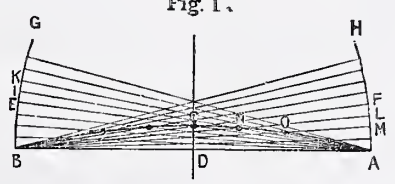

Fig. 2.

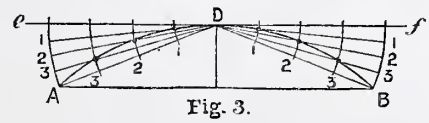

Fig. 3.

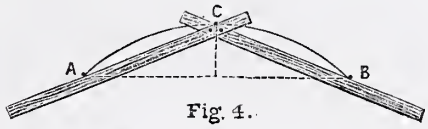

Fig. 4.

Diagrams illustrating Methods of Striking Curves.

subtract the square root so obtained from the radius of A. The formula is put thus: E = radius A minus

$\sqrt{\text{radius A}^2 - \text{D}^2}$. Reckoning it out:

| | |
|---|---|
| A squared | = 22,629,049 in. |
| D ,, | = 14,400 in. |
| $\text{D}^2$ minus $\text{A}^2$ | = 22,614,649 in. |

The square root of 22,614,649 in. is 4,755·48 in., and 4,755·48 in. subtracted from the radius of A = 1·52 in., and this is the height, E, which you require—say, $1\frac{1}{2}$ in. full. There are three ways employed in the shops for striking these very flat curves after the height, E, is known. In Fig. 2, A B is the chord, and C D the height of the versed sine, and the curve has to pass through the points A, B, C. From the extreme points, A, B, as centres, describe arcs, A H, B G. Through the third point, C, draw A E, B F, cutting the arcs. Divide A F and B E into any number of equal parts, and set off a series of equal parts of the same length on the upper portions of the arcs beyond the points E, F. Draw straight lines, B L, B M, etc., to the divisions in A, and A I, A K, etc., to the divisions in B. The successive intersections, N, O, etc., of these lines are points in the circle required, which may be filled in accordingly. Similarly the remaining part of the curve, B C, may be described. In Fig. 3 let A, D, B, be the given points. Draw A B, A D, D B, and also *e f*, parallel to A B. Divide D A, D B, into a number of equal parts at 1, 2, 3, and from D describe arcs through these points to meet *e f*. Divide the arcs A *e*, B *f*, into the same number of equal parts, and draw straight lines from D to the points of division. The intersections of these lines successively with the arcs 1, 2, 3, are points in the circle to be filled in. In Fig. 4 two straight-edges are screwed together, touching the ends, A, B, of the chord, and crossing at the point C, where the versed sine cuts the circle. A similar point is fixed at C, and pins are driven into the templet plate at A and B. When the straight-edges are slid around the pins, A, B, the pointer will mark the curve, A C B.—J.

**Watch Plates.**—AMATEUR WATCH JOBBER.—The reason of the watch plates looking so white after cleaning is that you, or someone before you, have brushed all the gilding off, and the only way I know of getting it to its original colour is to gild it anew. Send the plates by registered post, in a wooden box, to Messrs. Grimshaw & Co., 35, Goswell Road, Clerkenwell, or Haswell & Sons, 49, Spencer Street, Clerkenwell, and tell them to regild. The cost will only be a shilling or two, at most. There is no other remedy I know of.—A. B. C.

**Influence Machine.**—STUDENT (*Hull*).—You will find an illustrated description of an influence machine in WORK, No. 88, Vol. II., published Nov. 22nd, 1890, under the head of "A Cheap and Simple Electrical Induction Machine." Other forms might be described, but this will give you an idea how to make one.—G. E. B.

**Electro-plating Brass.**—T. C. W. (*Hull*).—I cannot advise you to attempt electro-plating at home a brass article having a superficial area of 4 ft. To do this job you will require a vessel capable of holding at least fifty gallons of silver solution, and this will cost from £2 to £3. The silver solution will cost about 15s. per gallon, or, say, £37. The silver sheet for anodes will cost £50, and the battery from £2 to £3 more. These are the chief items of expense likely to be incurred in plant alone, which will cost a total of at least £100. A professional plater will do the job for about £2, and do it better than you can possibly do it at home. If you do not know a professional plater, write again to us, or ask Mr. Hartley, 13, St. Paul's Square, Birmingham, to quote you a price for the job.—G. E. B.

**Medical Electricity.**—HÆREO (*Dover*).—Your medical adviser was quite right in warning you against the use of a coil for the cure of your nervous disorder. The current from a coil, and also from a shocking machine, is interrupted, intermittent, and alternating. It is a see-saw movement, most irritating and injurious to the nervous system. Such a current does not strengthen the nerves. Its tendency is toward an exhaustion of nerve-power. Unless your medical adviser instructed you how to use this potent remedy, you will do well to avoid it altogether. Replying to your other question, an *uninterrupted current* for medical purposes is obtained from a large number of small cells arranged in series, so as to get a high electromotive force capable of surmounting the enormous resistance of the human body. From 30 to 50 cells of the Leclanché type are usually employed. Mr. K. Seball, 55, Wigmore Street, London, W., will supply a 40-cell battery at the price of £5 15s.—G. E. B.

**Electro-magnets.**—W. G. (*Wandsworth, S.W.*).—You will find this subject fully treated in one of the Cantor lectures given by Professor Silvanus P. Thompson. You can get the lecture above mentioned. You may then study the principles of construction of electro-magnets, and apply these to your requirements. Had you stated these in your letter, I could have helped you over the stile. It is not enough to say you want electro-magnets and solenoids to work with a 100 volt current. This is a most important factor, and should have been stated; but one cannot design electro-magnets on this bare fact alone. I must know something about the volume of current as well as its voltage, and also know its source, whether from a dynamo or battery. I must also know what work is to be done with the magnets and solenoids.—G. E. B.

**Incandescent Gas Light.**—C. N. V. (*Aldershot*).—I do not know the address of the Incandescent Gas Light Company. I have a patent incandescent gas burner, obtained at 81, High Holborn. This address is embossed on the burner.—G. E. B.

**Carpenters' and Cabinet-makers' Wages.**—WORKSHOP PRESIDENT.—A letter addressed to the Editor of the *Trades Unionist* will bring you a list of the Trade Union rate of wages. Perhaps some of our readers can also oblige with the information.—G. E. B.

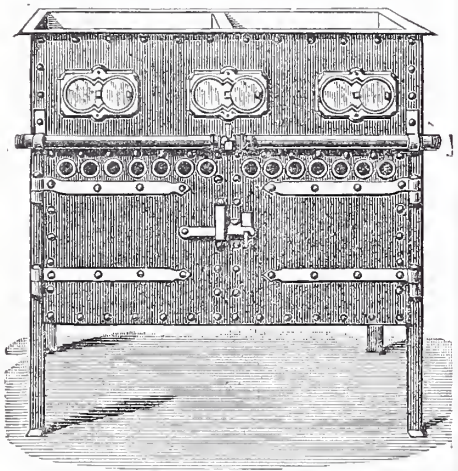
**Colouring Maps.**—C. N. V. (*Aldershot*).—The colours run when size is applied to maps for one or more of the following reasons: (1) The maps have not been properly prepared for colouring. (2) Bad colours have been employed. (3) Bad size has been used. (4) The size has not been rightly applied. (1) The maps must be sponged lightly with a solution of two teaspoonfuls of ox-gall in a pint of water, to remove grease before colouring. (2) The best moist water colours should be used, or Rowney and Co.'s cakes of colour. (3) Isinglass makes the best size; next to this comes gelatine. If these cannot be obtained, make your own size from parchment cuttings. (4) Apply the size hot, in a warm room free from dust and draught, with a broad 2 in. sable brush. Use this in one direction only. Don't brush the size to and fro, or it will lather and run the colour.—G. E. B.

**Accumulators.**—H. McM. (*Liverpool*).—(1) The full storage capacity of a storage battery can be ascertained by measuring the positive plates and reckoning six ampère hours to each square foot of positive surface. (2) The lead plates should be roughed or pierced with holes before applying the red lead or litharge paste, and this should be well pressed into the holes to ensure a good hold on the paste. If this is not done, the paste will peel off. (3) The storage qualities of the battery do not entirely depend upon the quantity of red lead put around the plates, but upon the quantity of lead oxide converted by the electric current into lead peroxide. There must be a practical limit to the

thickness of the coat of lead oxide we can get to hold on to the lead plate, even when this has been pierced with holes. When this has been converted into lead peroxide, it has a slate colour. (4) The size of the cells is determined by the volume of current to be obtained from them, together with the required pressure of the current. Large cells must be used if a large volume of current in ampères is required. As each cell gives a pressure of two volts, we must have enough cells in series to push the required current through the work to be done. (5) Cells may not be made of metal, because this would be destroyed by the acid, and would form a galvanic pair within the battery, thus short-circuiting and ruining the plates.—G. E. B.

**Worked Brass.**—BELFAST.—The proper "lacquering" of polished brass is a difficult matter, and requires considerable practice, but the best substitute is "Zapon," made by the Crane Chemical Co., Newhall Hill, Birmingham (directions for its use are supplied with it); or "Silico Enamel," purchasable at almost any cyclists' warehouse, will answer very well. All the articles should be slightly warmed, and then brushed over with the enamel or varnish. Gawthorp's (16, Long Acre, London) "Book of Designs for Repoussé," 1s. 1d. post free; or "Home Art Work" (Heywood, Paternoster Row), might suit you for designs; while, for the practical working, Haslope's "Repoussé Work," 2s. 6d. (Gill, 170, Strand), or Gawthorp's "Hints," 6½d. post free, are most likely to be useful.—J. G.

**Book on Electro-plating.**—WYNBERG.—The best work on electro-plating is "Electro-metallurgy," by A. Watt, price 9s. (Crosby Lockwood & Co.). The cheapest and best book, according to press notices and the testimony of practical platers, is the "Electro-platers' Handbook," price 3s., published by Messrs. Whittaker & Co., 2, White Hart Street, Paternoster Square, London, E.C. This is a book specially written to meet the wants of amateurs and those who wish to learn the art.—G. E. B.



Small Fryer for Fish and Potatoes.

**Fish and Potato Fryers.**—WEEKLY READER.—The illustration given above is taken from the list of Messrs. Fletcher & Co., 77, Queen Victoria Street, E.C. It is scarcely large enough for the purpose required, but they will quote prices for any size. You will not require the oven. The canopy should be of zinc; and if you will let me know the size of pans, I will give directions for making the canopy, and the probable cost.—T. W.

**Cork to use with Glass-paper.**—J. W. C. (*Tavistock*).—You must apply to a cork cutter. You will find one in Plymouth, or, at all events, in one of the "three towns."—ED.

**Single Stroke Electric Bells.**—J. H. (*Bedford Leigh*).—Almost any number of single stroke electric bells may be rung on one circuit, providing the battery power is proportioned to the number of bells to be rung. If the bells are arranged in series, the total pushing power of the battery, or its E.M.F., must be high enough to send the required current through all the bell coils, and this may mean one additional cell to each additional bell. If the bells are all arranged in parallel on one circuit, the cells of the battery must also be arranged in parallel, or the cells of the battery must be large. In this case we must increase the size of the cells with each additional bell, or increase the surface area of the battery elements by adding cells in parallel, because we require a larger volume of current to ring all the bells at once. If you will give me the number of bells you wish to ring, and the size of the bells, I will try to aid you with advice respecting the battery.—G. E. B.

**Electric Bell Fitting.**—G. F. B. (*Notting Hill Gate*).—You will find some information on electric bells in WORK, Vol. I., Nos. 12, 18, 20, 27, 31, and 32. These are all in print, and may be obtained through any newsagent for 6d. "Electric Bells and All about Them," by Mr. Bottone, price 3s. post free from the author, who lives at Wallington, Surrey; or "Practical Electric Bell Fitting," by Mr. F. C. Allsop, 165, Queen Victoria Street, London, E.C., are both good books on the subject. Both authors sell the "stuff to make the bells," and sell bells ready made, together with the materials for fixing them.—G. E. B.

**Canoe and Boat.**—A. G. (*Dublin*).—For particulars of these, see WORK, Nos. 71 and 80.

**Camera Making.**—W. J. H. T. (*Birmingham*).—For articles on cameras, see WORK, Nos. 13 and 23. You should consult the Indexes to WORK, Vols. I. and II.

**Slide Hinge Photograph.**—NO NAME.—The neatest method of hingeing a folding dark slide is to cut the lower part of the shutter into strips about half an inch wide, fitting into each other by a simple rebate. The strips must fit each other accurately,

Diagram illustrating Slide Hinge for Dark Slide.

and, being laid down on a flat surface in close contact, glue over them on one side some thin leather or other tough material, and let them dry, after which they can be blacked. The accompanying diagram will explain the matter.

**Safety Bicycle Construction.**—J. W. T. (*Manchester*).—If J. W. T. procures the back numbers of WORK, he will find articles already published, entitled "Safety Bicycle Construction," and the last treats of the blowpipe and foot-blower.—A. S. P.

**Pneumatic Tire.**—E. G. (*Salford*).—Your correspondent seems to hold a patent for *one more* pneumatic tire. Being quite ignorant as to the nature of the patent tire, I can say nothing about it, except that if the steel ribbon referred to is essential to complete the patent, and has been put down in the specification, then I should say that, without the ribbon, the patent would be incomplete, and would only be of value in so far as it was found to be a good thing—what was of it—minus the ribbon. As to the procuring of this steel ribbon, the form would be somewhat after that of a mud-guard, only thinner, and the Birmingham sheet steel workers will turn out thin steel to any shape and pattern, and for any purpose, under the sun. It is only a question of cost; in this case, the making of a special pair of rolls.—A. S. P.

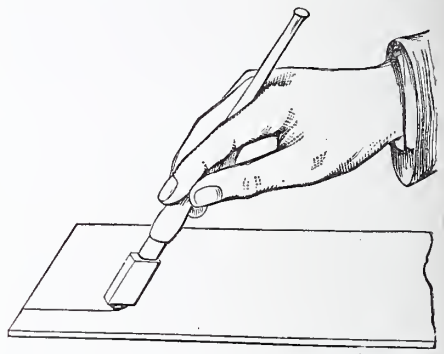
**Tandem Safety Bicycle.**—J. G. B. (*Clapham, S.W.*).—Without making a drawing of the machine, or having one to measure from, I could not give J. G. B. the relative dimensions. I could, however, give him this advice: "Don't make it." A tandem bicycle mounted by two young fellows, having no responsibilities, and somewhat reckless of life and limb, may be tolerated, but the idea of one of the riders being a lady should be given up, unless she has considerable acrobatic training. Let him go in for a tandem tricycle, which is in every way suitable for a lady. It is very little heavier, and nearly as fast. I should be glad to assist J. G. B. with sizes for a tandem bicycle, if he still thinks of going in for it, and will endeavour to procure dimensions, and give a drawing as well.—A. S. P.

**Staining and Polishing Cheap Furniture.**—J. E. B. (*Epworth*).—The processes of painting and polishing cheap furniture are entirely distinct trades, and are not usually done by the same person; but as you have, from instructions given in "Shop," succeeded in doing the former in a manner satisfactory to yourself, we may reasonably hope you may be successful with the latter process, if you will have confidence in yourself, for in this lies half the battle. The somewhat tedious process of French polishing—properly speaking—has to be dispensed with, the work being done mostly with a brush rather than a rubber. For mahogany or red-coloured furniture the work is given one or two coats of patent size and venetian red, applied hot; for walnut, umber is used. When this is dry, smooth with worn glass-paper; then give three or four coats of red varnish, applied with a brush. This should be done in a warm room. Some polishers, previous to applying the varnish, give the work a good wet rubber of polish. This is applied with wadding, omitting the rag covering. This plan, though not always adopted, has much to recommend it, the object being to seal, as it were, the pores of the wood, make the varnish take more kindly, and hold out smoother. Each coat of varnish should be allowed at least fifteen minutes to dry before the next is applied. When the last has stood this long, it is levelled by means of the rubber previously used, only with the rag covering. This rubber is used fairly wet with "half-and-half"—*i.e.*, half polish and half spirits. The rubber should present a quite level face, with the rag free from creases. This is best obtained by pressing its face on the palm of the hand or on the back of a worn piece of glass-paper, though you will see most polishers give it a tap on the underside or front of the work-bench. This rubber is now applied to the work with a light, swinging motion, lengthwise of the grain, never allowing it to remain still on the work an instant, the polish in the rubber being thinned out as required with methylated spirits only; though, if the work is not of the very cheapest class, its brilliancy will be enhanced by adding to the rubber a little glaze, on the use and composition of which you will find an article by Mr. Denning in WORK, No. 126, p. 338, August 15th issue. In the use of this rubber lies the want of confidence in one's own abilities. Just when to leave *off* is a happy knack that can only be acquired by practice and careful attention. Every care must be taken not to tear up the gums instead of levelling them. The varnish used is one in which resin plays an important part. A suitable varnish can be made as follows: Naphtha, 1 pint; shellac, 5 oz.; resin, 2 oz. (No. 2) Naphtha, 1 pint; shellac, 4 oz.; gum sandarach, 2 oz.; gum benzoin, 1 oz.; resin, ½ oz. The varnish should be carefully strained through fine muslin before using. For polish, use naphtha, 1 pint; shellac, 6 oz. To make the polish and varnish a red colour, use bismarck brown, first dissolving two-pennyworth in a ¼ pint of methylated spirits.—LIFEBOAT.

**Ebony Walking Stick.**—EBONY.—The fact of your stick showing so many white marks points to the conclusion that it is not an ebony one, but one made of some cheaper wood stained and varnished, the varnish being of a soft kind. The best thing I can advise you to do is to glass-paper it quite smooth, and send to Mr. Flack, Steam Works, 75, Blackman Street, London, S.E., for a small bottle of his ebonite French polish and spirit varnish, telling him the purpose for which you need it; or buy a small tin (about 5d.) of black enamel, Foo-Chow brand. Both these may be applied with a camel-hair brush, and will to you, with your inexperience of such matters, give a far more satisfactory result than trying to work it up with French polish.—LIFEBOAT.

**Optical Illusion for Use in Advertising.**—W. E. W. (*Wimbledon*).—The application of an old and well-known principle to advertising purposes could scarcely be made the subject either of a patent or of registration, and in this case we presume that W. E. W. will have to rely on the honour of the advertising firm to whom he offers his idea.—C. C. C.

**Cutting Glass.**—AMATEUR CUTTER.—The reason your glass does not break properly is that the diamond has not cut it all the way, and the fault lies in the holding of it. I suppose it is the top part that breaks properly, and not the bottom; this is generally the case. If so, you hold the diamond correctly when commencing the cut, but, in bringing it down, gradually get it too upright. The accompanying drawing will show you the correct way to hold it. You will notice the bottom, to which the diamond is affixed, is kept parallel with the glass. This must



Mode of holding Hand, etc., when cutting Glass.

be so all the way. The fingers should be kept stiff, and not moved as when holding a pen in writing. It will help you, when you have made the cut, to lay the glass on a board or table with a straight-edge, get the cut exactly over the edge of the board, hold one part of the glass firmly, and press the other downwards, when it should break clean, and follow the cut all the way. I shall be pleased to help you at any time. Glad you like the paper, and thank you for kind wishes.—W. E. D., JR.

**Making Improved Pipe-stem in Vulcanite.**—JACK PLANE.—Vulcanite is simply indiarubber combined with sulphur and colouring matter, and hardened by heat and pressure. But the heat has to be very great—some 315°; so has the pressure—some 80 lbs. to the square inch. The manufacture is not one to be carried on as a home industry; it needs special skill and costly appliances. As JACK PLANE has protected his invention, and fears no piracy, he is strongly recommended to arrange with some firm of manufacturers for the fabrication of his stems, rather than attempt to make them himself.—M. M.

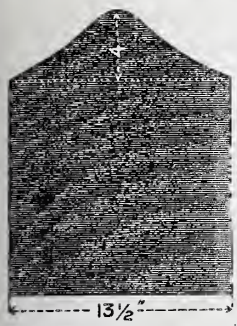
**New Combination Saucer.**—W. E. W. (*Wimbledon*).—To your query No. 1, we should say that undoubtedly your idea is a fit subject for a patent. To No. 2, whether it would be *worth* patenting, it is impossible to give a definite answer. If the trifling cost of provisional protection is not an object to you, we should say, get such protection, and then show your plan to some of the great pottery firms. If you do not care to risk any money, you might offer them the idea, trusting to their good faith. Such firms will be (query No. 3) the persons to purchase your patent rights or to pay a royalty on working them, if the idea should be thought to have commercial value. We do not question but that in this trade there would be a desire to produce novelties.—C. C. C.

**Plaster Casts.**—E. J. (*Yeovil*) wishes to procure large-sized plaster casts of the statesmen of the present day. Probably the largest assortment of casts in this country is at Messrs. D. Bruchiani and Co.'s, Russell St., Covent Garden, London, W.C.; and so far as the matters required are in the market, this firm will be likely to have them.—M. M.

**Greenhouse Boiler.**—J. B. (*Manchester*).—No; there is no danger in working your boiler if your

supply cistern is an open one, which it no doubt is. The worst that could happen, if the corroded plates gave out, would be the leakage of the water into the greenhouse, and even this would be gradual, unless your feed cistern is a considerable height, which is scarcely likely to be the case. I think, however, that you did wisely in asking the question. —R. A.

**Gas Generator for Brazing.**—A. J. (*London, N.*).—It will not answer for brazing or shop repairs. Messrs. Fletcher & Co. distinctly state that petroleum gas and producer gases, though satisfactory for furnaces, are *very difficult* to use with any open blowpipe for the above purposes (see p. 90 of their new catalogue).—R. A.



Marking Elbow Pipe.

**Elbow Pipe.**—F. H. (*Witcolmtee*).—Mark your sheet metal out as shown in sketch (seams are allowed for), and after rolling and seaming, trim the edges until level. If you cannot trust your eye to trim it, dip the half elbow in a shallow pan of water, and cut round by the water-line. It would require a full-page article in WORK to describe the geometrical method of marking out an elbow, but you will find this sufficient for all practical purposes.—T. W.

**Improved Watch-key.**—F. M. (*Portsea*).—I have carefully examined the model sent us by our correspondent, and I fail to see any novelty in the arrangement over one I used in 1834-6 (which was of French origin), except the little tightening screw. In these days of the extending use of keyless watches and their great convenience, it seems to me a waste of time and trouble to attempt to perpetuate the use of keys; and even assuming that it were, there does not seem to me to be sufficient advantage to be obtained to lead me to advise either its being patented or introduced, as there is great want of novelty.—C. E.

**Ornamental Designs in Cardboard.**—D. B. D. (*Glasgow*).—You are quite right in your views as to the want of novelty in the so-called card-cutting business to which the name of "castography" has been given, but it is far more ancient than the time you name. When a schoolboy in 1838 I was taught to cut these cards by a young Frenchman of my acquaintance. There is no douht that the judicious use of colour, as suggested by you, would be an improvement.—C. E.

**Incubator.**—INCUBATOR.—If not in your possession, order Nos. 41, 89, 99, and 109 from your bookseller, or the publishers will send them post free for 5d. In these you will find something about the subject, and in the course of a few weeks an article will be published dealing with a hot-air machine. There is plenty of time yet to prepare a machine for use next season.—LEGHORN.

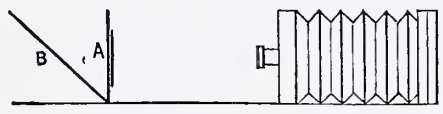
**Incubator.**—D. A. (*East Cambus*).—In page 75, Vol. III., No. 109, you will find a description of a regulator which will suit you.—LEGHORN.

**Tracing Patterns for Crewel-work.**—A LOVER OF "WORK" asks the nature of that composition which may be trausferred from the pattern paper to the material hy pressing with a warm flat-iron. It is simply white wax melted up with vermilion or some other colouring suhstanco. With this the pattern is *printed* upon the paper; but if A LOVER OF "WORK" is proposing to draw designs for crewel-work which are *not* to be printed, this will be of no use to him. His plan will bc to draw the design on paper—any white paper if the design is complete in itself, but if the pattern repeats, or has in any way to be joined accurately to other parts, he should use tracing-paper. He will prick holes along the lines of the design. If the fabric is of a light colour, he will pounce upon it through the holes with a vermilion or blue powder, and then with a camel-hair brush and water colour of the same hue, go over the line of dots. This is necessary; without it, the dry pounce colour would dust out in course of working, and the pattern be lost. If the fabric is dark, he will pounce with chalk or flake white, and line with Chinese white. —S. W.

**Expanding Envelopes.**—R. J. H. (*Penzance*).—I find that your envelope stands the test of cramming in a highly satisfaetory manner. When only moderately charged, it is scarcely less neat than the ordinary envelopes, but when the "expanding" and the ordinary envelope are alike charged with heavy budgets, the superior capacity and neatness of the former are evident. I see no reason why it should not be successful with the stationery trade, provided, after due search, you find that the idea has not been anticipated. It appears possible that the gussets may act as traps for the corners of other letters and cards when in the mail-bags, and that in transit such corners may he forced through your envelope. Whether this objection is of any weight can only be proved in practice; but should it be so, I would suggest a linen lining for the gussets.—C. C. C.

**Repairing Brass Wind Instruments.**—B. S. (*Kinsale*).—If our correspondent will provide himself with a soldering-iron, a blowpipe, some soft solder, and spirits of salts, there are many little repairs which he can do. Of course, he must have some sheet brass and a pair of metal cutters. I presume he has had some experience in the use of the soldering-iron; if not, a very little practice will make him sufficiently expert to solder a broken slide or stay. In patching, care should be taken to shape the piece to be soldered on to the curve of the tube on which it is to be fixed before attempting to solder it. After the soldering, the lead round the patch or stay can be removed by scraping, after which a ruh of emery-cloth and a little polishing with powdered rotten-stone and oil will make a clean and neat joh. In order to hold the two surfaces together whilst heing soldered, fine wire is used. In a previous number some hints were given upon the removal of hruises, etc., and these would he useful to our correspondent. In soldering any stays which are fixed to the valve boxes, care must be taken not tn overheat the latter, or expansion of the metal may prevent the proper working of the valves.—G.

**Daylight Camera.**—LIGHT.—A camera to be used by daylight is exactly the same as one used for artificial light. The only difference is in the illumination of the ohject to be copied. With artificial light it is necessary to use a condenser, but in daylight a reflector is used instead, placed at an angle of forty-five degrees; with regard to the transparency to be copied, all light but that passing through the transparency being carefullycut off. In case of only a portion of the transparency requiring to be copied, an opaque mask of paper should be affixed to the back of the transparency, cutting off all the subject not required. By this means a more brilliant copy is secured. It is an axiom never to use any more light than is absolutely required. The arrangement of camera and reflector is shown in diagram. The reflector must be considerably



Daylight Camera—A, Transparency; B, Reflector.

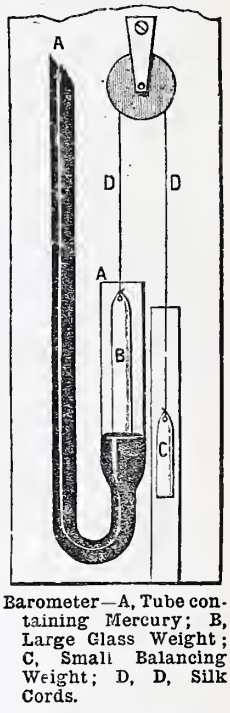
larger than the transparency, or the whole of it will not be evenly illuminated. The reflector may be a mirror or any dead white surface.—D.

**Transparent Varnish.**—DENIS.—I append a few rccipes for transparent spirit varnish, but for such a small quantity as you will require for your holly walking stick, I cannot advise you to make; the cost of the gums, buying in such small quantities, would make a dear varnish. I would rather advise you to go to a respectable oil and colour merchant, and buy a quarter of a pint of transparent spirit varnish or copal varnish. The latter is an oil varnish; and though it takes much longer to dry —say, twelve hours for each coat applied—it will stand hard wear much the best. (No. 1) White spirit varnish: one pint rectified spirits, 4 oz. white shellac, 2 oz. gum sandarach, 1 oz. gum henzoin, ½ oz. pale resin. (No. 2) Colourless varnish: half-pint turpentine, 4 oz. pale resin, 1 oz. gum sandarach. (No. 3) Quarter-pint of clear Venice turpentine, 4 oz. gum sandarach, 2 oz. gum mastic. (No. 4) One pint spirits of wine, gum copal 4 oz., camphor ½ oz., mastic 1 oz., Venice turpentine 1 oz. The gums should be finely crushed before adding to the spirits, then set in a warm place to dissolve. Carefully strain before using. Apply with a camel-hair brush in a warm room.—LIFEBOAT.

**Preserving Glue, Gum, and Paste.**—NORFOLK (*Norwich*) wishes to know "how to keep glue, gums, and paste in a liquid condition without fermenting or turning mouldy." Liquid glue is usually prepared by dissolving the glue in alcohol, or in a little water, and then thinning with alcohol; the spirit acts as a preservative. Gum may be kept in much the same manner: viz., by dissolving in water, and then adding spirit. Some, however, recommend the preservation of liquid gum hy the addition of strong vinegar or acetic acid instead of spirit. The preservatives which have been used for paste are mostly poisonous. Some recommend putting in a little sugar of lead, others corrosive sublimate; carbolic acid has also been employed. It will be seen to be so in the following recipe: Carbolic acid, ½ oz., mixed in a pint of water, and made into paste with 4 oz. of flour; it is said that paste thus made will keep good for years. Another formula is: finest flour three parts, fine white sugar one part, and a few drops of carbolic acid to he stirred in whilst the paste cools; this paste is also reputed to keep well, and to he of a superior colour. It is said that paste may be preserved from souring by alum alone if made as follows: dissolve a teaspoonful of powdered alum in a little boiling water, and with this mix a table-spoonful of flour, beat to a batter, and slowly pour in hoiling water till it turns.—S. W.

**Repairing Keeper-rings.**—AURORA.—The particulars asked for are "how to repair an ordinary keeper-ring when it has heen broken through in several places where deep hollows are either engraved, chased, or filed, thus making the ring too weak for ordinary wear." Of course, the evident answer is: solder the pieces together once more, and do not cut the hollows so deep again. Now, if soldering is the difficulty, it will be cleared up if AURORA refers to page 732, No. 46, Vol. I., and to page 388, No. 76, Vol. II., and there are several other replies in "Shop," which can be found on referring to the Index. If none of these clear up the difficulty, then AURORA must write again, taking care to give full particulars as far as possible of the part of the process where the difficulty arises. We that are connected with WORK are willing to help, but we should like to know the exact point on which advice is asked, for no human being can tell exactly where another will find his difficulties. It is most likely, though, that he does not know how to fix the pieces togetber while soldering, so I will give one or two methods. First tie the pieces together by passing a strand of medium (No. 24) iron hinding wire round the parts, cross the ends, and twist them up quite tight with a pair of pliers. That method may not do if the ring is in several pieces, so try No. 2—thus: Turn up a piece of thin iron plate the shape of a ring, and the exact size of the inside of the ring. To this iron ring tie all the pieces, so that each piece is clcse up to the next one, when they can be soldered all at once, or in two or three solderings, as you choose. Third method: Arrange the picces edgeways on a flat piece of charcoal or pumice. If they will not remain steady enough for soldering, press them slightly into the charcoal. If that is not sufficient, then steady them with pegs of iron wire, which can be driven into the charcoal or else try an original Indian method: viz., use small heaps of moist loam placed in two or three places inside and outside the ring; failing that, try moist whiting. One word of caution: do not let any of the last-mentioned materials get into the place where your solder is to go. And in soldering the gold ring with an iron plate inside, take care how the heat is applied, or the ring may get melted, if it be made of 9-ct. gold, as a great many keeper-rings are. There is not much to fear, though, if your solder is of a suitable quality, and your work and borax, etc., etc., is quite clean, and your heat is applied gently. —H. S. G.

**Repairing Barometer.**—LEWIS.—This is rather a difficult operation, and will require great care to make a good job of it. The mercury should be as pure as possihle. Try it by dropping a little on a white china plate; if it runs ahout and forms bright round drops without leaving a mark, it will do, hut should it form into pear-shaped drops, and show where it has been by dull metallic marks, it is impure—most likely by adulteration with lead—and should be rejected; any way, it is as well to filter it by making pinholes in a sheet of clean white paper, and passing the mercury through; it should afterwards be boiled, to expel the air, and is then ready to bc poured into the tube. This should be done as gently as possible, so as not to take any more air into the tube than can be helped. Even with the greatest care some air-buhbles will, no douht, form, and to ensure correct working these must be got rid of. The proper way to do this is to boil the mercury in the tube by passing it over the flame of a spirit-lamp, commencing at the top. You must be very careful not to crack the tube. Should you not care to risk it, you may try shaking the mercury in the tube, and so cause the air-bubhles to come to the open end. This is a long and troublesome operation, but, on the whole, safer for a novice than the first, although the best results cannot be obtained by this method. In regard to the other part of your letter, I send a small sketch, showing how the weights ought to be fixed, so that you need make no mistake. You will observe that the largest should be in the mercury. The small glass tuhe certainly ought not to have any mercury in it; its use is simply to contain the small balancing weight, so that it may work freely. Regulate the height of the mercury and position of the hands by another one.—W. E. D., JR.



Barometer—A, Tube containing Mercury; B, Large Glass Weight; C, Small Balancing Weight; D, D, Silk Cords.

**Castings for ¼ H.-P. Steam Engine.**—E. S. F. (*Charlton*).—Arrangements are heing made for the speedy productiou of these.—ED.

## III.—QUESTIONS SUBMITTED TO CORRESPONDENTS.

**Jewel-case Making.**—WOODWORKER writes:—"I should like to know how to go about to make a cast from tho outset for a silver tea-set, consisting of a sugar-hasin, cream-jug, and tongs, the two

former articles to be fitted in a canted position: which, I think, is the way they are most generally done. This question concerns only how to make out pattern and the woodwork, including 'fitting.' Supposing the articles are before you, what is the first step to take in planning out pattern for a shaped morocco tea-set case?"

**Locks.**—J. G. (*Bloomsbury*) writes:—"Will any reader kindly tell me where I can get letter locks made wholesale? I believe it is somewhere abroad."

**Punt.**—H. (*Tunbridge*) writes:—"Can any reader give me the sizes, etc., for constructing a punt to hold, say, six persons comfortably?"

**Saw.**—TOP SAWYER writes:—"With regard to saw sketched by W. W. (*Caverton*) (see p. 347, No. 126), it will simplify the work of fitting up for me and many another reader if W. W. would kindly give following measurements and particulars from his: (1) What are the length and thickness of wood spring? (2) What wood did he use for his spring? (3) How long is the saw? (4) What length is treadle? and where is weight placed, and for what purpose?"

**Firewood.**—F. B. (*Rochdale*) writes:—"Will any of our brother readers inform me how to make a firewood bundling machine—that is, to hold the wood firm when being tied? the wood to be cut in lengths of 7 in., and each bundle to be 6 in. in diameter. A description of the above machine will oblige."

**Brass Scraps.**—J. J. J. (*Morriston*) writes:—"Will any reader kindly give me the address of some brass founders who would buy yellow metal scraps and turnings, etc.?"

**Harp.**—TELYN writes:—"I should be pleased if some of our numerous kind musical friends could give me the dimensions of a pedal harp, either single or double. Any information I should be glad of."

## IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Chair Cane.**—G. H. (*Shaftesbury*) writes, in reply to J. T. (*Shadwell, E.*) (see p. 350, Vol. III.):—"I can supply him with dressed chair cane at 2s. 8d. per lb. for fine, and 2s. 3d. per lb. for coarse."—[G. H. should advertise in our cheap "Sale and Exchange" column; but if J. T. (*Shadwell*) sends a prepaid letter, it shall be forwarded.—ED.]

**Egyptian Trellis Work.**—H. C. T. (*Newcastle-on-Tyne*) writes to T. E. P. (*Cambridge*):—"I see in WORK for October 26, page 508 (Vol. I.), that C. H. O. invites me to communicate with you on the above class of work. I shall be very pleased to do what I can for you or any other reader of WORK; having had a good deal of practical experience of this work, I can give advice in detail. Any reader wanting any of this work done or any further particulars, I have no doubt the Editor will kindly give them my address, when I will do my best to oblige any correspondent."

**Artist's Easel.**—H. J. M. (*Bristol*) writes, in reply to S. A. W. (*Wallasey*):—"Seeing in my monthly part of WORK a question by S. A. W. (*Wallasey*), *re* an artist's easel, perhaps the following sketch and explanation may be useful to him. It is very light and portable, and one I made for myself about eighteen months ago, and I have found it answer its purpose very well. It consists of three legs hinged to head-piece, and connected by a loose cross-piece made of beech wood. The hinges I have found answer best for this particular easel are made of two little brass plates and a piece of leather (Fig. 2); the ordinary hinges I found broke off after a little use. The legs and head-piece are ¾ in. square, and the cross-piece as shown. To secure the cross-piece, I have utilised the ordinary window screws and plates (brass). The first plate has a free hole, the second is tapped to take the screw, and, of course, is put on the side of the easel leg farthest away from the thumb-piece of screw; the guide-plate is fitted to the cross-piece of easel. There are three sets of holes, each hole having a plate fitted to it. To hold my painting firm, I use a small clamp over the head-piece. Although at first sight this may seem to some a very flimsy structure, I can assure them it is far from being flimsy, and is exceedingly rigid when set up, considering the bareness of its mechanical construction. I have found it extremely useful for out-of-doors sketching. That is the reason of the pointed ends to the legs; they are useful for sticking into the ground. The cost of the whole would be about 3s., and if S. A. W. desires any further particulars or explanation, I shall be most happy to oblige him. The only tools he would want to use would be a plane, bradawl, screwdriver, and saw. The rebate he could manage with the tenon saw, securing the cross-piece at sides and either end, and then sawing first one way and then the other."

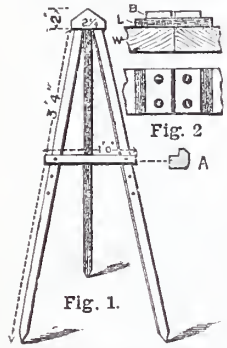


Fig. 2

Fig. 1.

**Fig. 1.—Artist's Easel complete — A, Enlarged Section of Cross-piece. Fig. 2.—Mode of Hingeing in Plan and Section — B, Brass Hinge; L, Leather; W, Wood.**

**Fret Machine Parts.**—NORTH JACK writes, in reply to LANCASHIRE (see p. 334, No. 125):—"I beg to enclose rough sketch of the back part of the saw-frame. In Fig. 1 will be seen back view of arm-piece, showing four plates bent at right angles, and screwed on at back. A small iron pin, ¼ in. diameter, is run through as shown. Fig. 2 illustrates side view, with part in section to show the mortise

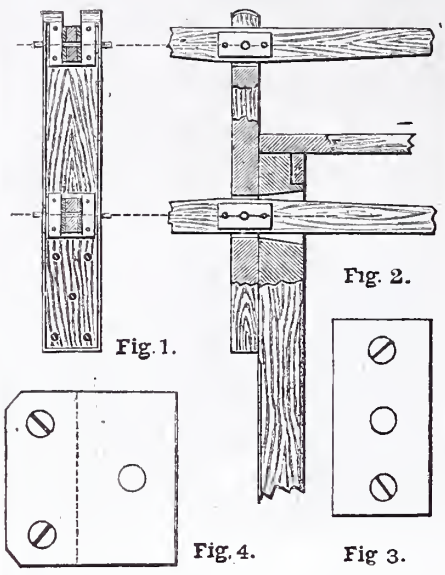

Fig. 2.

Fig. 1.

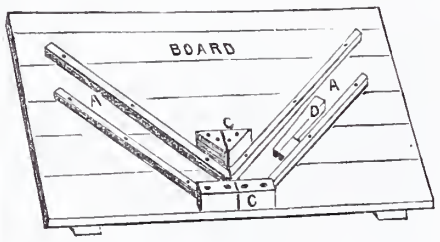
Fig. 4.

Fig 3.

**Fig. 1.—Back View of Arm-piece. Fig. 2.—Side View of Arm-piece. Fig. 3.—Brass Plate for Arms. Fig. 4.—Brass Plate bent at Right Angles.**

through the upright, and the plates let into the arms. Fig. 3 indicates brass plate for arms, 2 in. long, 1 in. wide. Fig. 4 shows plate which is bent at right angles (see Fig. 1) through the dotted line. The stroke is not quite perpendicular, but the difference is so small that it cannot be noticed while cutting."

**Mitre Cutting.**—R. T. B. (*Holbeck*) writes:—"In WORK, No. 72, page 323, POST OFFICE BOX asks for experience concerning mitre cutting. When I first began picture framing, I tried mitre boxes, blocks, and shooting-boards, but could get none of them perfect. I set to and invented a mitre-cutting board for myself. After the second attempt I got one together which is very simple. I submit a sketch of it which, I think, explains itself. It is on



**Board for Mitre Cutting.**

a stout board, 2 ft. by 3 ft.; so anyone can form an idea of the size. A is where you put your moulding; C, saw cut; D is an ordinary compositor's sidestick and a quoin, to hold the moulding in its place. I have an ordinary mitre-cramp, which can be bought at any ironmonger's or tool shop. With these I can get a mitre true and clean enough for anything, cut with a very fine saw."—[Back numbers of WORK can be obtained of the publishers, Cassell & Co., Ld., Ludgate Hill, London, E.C.—ED.]

## V.—BRIEF ACKNOWLEDGMENTS.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—F. C. (*Belfast*); EXPECTANT; B. B. (*Bradford*); G. M. H. (*Derbyshire*); C. G. M. (*Truro*); W. A. R. (*Queen's Co.*); R. D. O. (*Elgin*); S. S. (*Stockton*); T. D. (*Halifax*); F. H. B. (*Essex*); G. P. (*Elgin*); CYLTINE MANIFOLD COPYING MACHINE CO.; M. & C. (*Grimsby*); A CONSTANT SUBSCRIBER; G. F. C. (*Southampton*); R. R. (*Wigan*); T. A. D. (*Royton*); CHOPSTICK; C. H. SOME LESSONS IN WINDOW MAKING—GREENHOUSE SASHES.

## SOME LESSONS IN WINDOW MAKING.

BY G. LE BRUN.

### Greenhouse Sashes or Dead Lights.

Among the many and varied jobs undertaken by the average worker in wood, that of sash making seems at first sight to present the most difficulties, and very few amateurs in the art of carpentry ever attempt the putting together of even a simple form of window-sash; while the young professional, during his apprenticeship, considers himself almost fully fledged when he has mastered the subtleties of setting out a hung window and fitting together the cross-bars thereof.

Now, there is very little mystery in the matter, and no reason why the worker whose head is clear enough to overcome the difficulties attaching to dovetailing, mitring, mortising, and tenoning, should not grasp, by the aid of a few plain instructions and drawings, the art of putting together a window-sash. To those amateurs who go in for greenhouse building or for the making of forcing-frames, the knowledge of how to construct their own sashes will be of much service, for it is within my own knowledge that many clever workers in wood are deterred from working in this direction from their inability to put together the requisite framing.

Premising, then, that the aspiring sash maker has already overcome the difficulties of mortising and tenoning, and can use his tools fairly well, I will endeavour to clear his path for the making of his first sash, which shall be of a simple form, and of the appearance shown at Fig. 1. The wood used for the first attempt should be clean yellow pine. This wood is not in general use for sashes that are to stand much wear and tear—red pine, pitch pine, oak, and sometimes mahogany and teak, are used—but for ease in working, if the worker can choose his wood, by all means let it be yellow pine.

For the window before us, which measures, over all, 3 ft. in height by 2 ft. 6 in. in width, there will be required two stiles, 3 ft. 3 in. by $2\frac{1}{4}$ in. by 2 in.; one top rail, 2 ft. 7 in. by $2\frac{1}{4}$ in. by 2 in.; one sole rail, 2 ft. 7 in. by $3\frac{1}{2}$ in. by 2 in.; two sash-bars, 3 ft. 1 in. by 2 in. by $\frac{5}{8}$ in.; and two sash-bars, 2 ft. 4 in. by 2 in. by $\frac{5}{8}$ in. Plane up all the stuff very accurately, and gauge the width and thickness of each piece to a shaving, as upon the accuracy of the preparing of the stuff much of the success of the finished sash depends; especially is this so in the thicknessing of the sash-bars, and to get them right you should run the double template, supplied with your sash-planes, along the edges of each; when the template will fit tightly all along the length of the bar, the thickness is correct.

In planing up the stiles and rails, the face and edge of each must be planed so that the grain of the wood runs in the same direction (this is illustrated by the arrows in Fig. 2), and marked with pencil, so that they can be easily recognised. The object of getting the grain of the wood to run thus is that the glass check and sash-plane may work freely and clean along the framing, as, if either side or edge ran the wrong way, the wood would be almost certain to tear up in splinters when working these planes.

Having got the wood all prepared, you can now proceed to "set out" your sash. To do this, lay the two stiles on the bench, the marked sides outwards and the marked edges uppermost (Fig. 2). See that the ends are flush, and with a small square draw a line across the top edges of the stiles $1\frac{1}{2}$ in. from the left-hand end (A, Fig. 2). Measure off from this line 3 ft., and square across as before (B); these two marks are the exact height of the finished window; the $1\frac{1}{2}$ in. of over-wood at each end is not cut off until the sash is finished and ready to fit in its place. Technically, they are called "stumps," and they serve to prevent the splitting of the stile when mortising and wedging up. From the marks which you have just made measure inwards the thickness of your rails, which will be at the top $2\frac{1}{4}$ in., and at the bottom $3\frac{1}{2}$ in. (C, C). Again, measure from the outer top mark, $\frac{7}{8}$ in., and from the outer lower mark, $1\frac{1}{4}$ in., and draw lines across (D, D). Square across the marks D, D, C, C, and draw them on the under edges of the stiles, drawing additional lines $\frac{1}{4}$ in. to the outside of each; these outer lines are those you work to at the back of the mortise, which is tapered towards the front edge, as shown by the dotted lines in the figure. This taper is to allow for the insertion of the wedges that hold the framing together when completed. Before turning over the stiles to draw these marks on the back, you will require to set out the mortises for the sash-bars on the upper edge. To do this, divide the distance between C, C, into three equal parts, drawing your lines across for a mortise $\frac{5}{8}$ in. long; these mortises do not go through the stile, but are 1 in. deep, and in making them, if you have not got a mortising machine at hand, the best way is to bore a $\frac{1}{2}$ in. hole with a centre-bit, and then square the mortise up with a $\frac{1}{2}$ in. chisel. Work accurately to your marks, as if these mortises are too wide, the sash-bars will fit in a loose and shaky manner. And here I would remark that in setting out sashes, or other work requiring accuracy of workmanship, you must avoid using a pencil to square off your marks, and use a drawing-knife instead; otherwise, your work will never be satisfactory or workmanlike.

Having set out the stiles, the rails will now occupy your attention. Lay them on the bench in the same way as before, putting a piece of wood under the narrow one to bring its edge level with the wider one. Draw a line across, $\frac{1}{2}$ in. from left-hand end, as A, in Fig. 3. Measure off 2 ft. 6 in., and draw the line B; draw the lines C, C, $2\frac{1}{4}$ in. inside of the outer marks, the lines D, D, $\frac{3}{16}$ in., and E, E, $\frac{5}{16}$ in. from C, C. Square D, D, across the back of each rail, and E, E, across the face; these marks are cut in for the shoulders when you come to tenon. (See Fig. 4, which shows the end of the rail with tenons cut.) Divide the length between E, C, into three equal spaces, and set out sash-bar mortises as in the stiles, but with this difference: that instead of only going into the wood 1 in., they go right through, and are tapered for the wedge-grip in a similar manner to the rail mortises.

To set out the sash-bars, you have only to lay them on the stiles and rails, and mark them off, squaring your marks across on both sides, and taking particular care to allow for the fitting to the moulding and glass check of the upright bars by squaring off the end tenons $\frac{3}{16}$ in. and $\frac{5}{16}$ in., respectively, longer than the daylight marks at C, C, on the stiles. Of course, in doing this you will bear in mind that the ends of the horizontal bars go right through the stiles, while the ends of the upright ones only go into the rails one inch. Where the sash-bars cross each other is likely to prove the most trying part of the job to the novice, and is very difficult to explain on paper, but by the aid of an illustration I will endeavour to make it plain. When you have marked the mortises on the sash-bars, and squared them across on both sides, divide them *exactly* in the centre, draw a line (A) across, then $\frac{3}{16}$ in. from the outer marks, draw other two lines (B, B). You must draw these lines on both sides of the bar, and a glance at Fig. 5 will show you their position; this diagram is full size, and also shows the markings of the mortise gauge. Your framing is now all set out, and requires gauging off for mortising. Fix upon the chisel you are going to use—it must be a $\frac{1}{2}$ in. one—and set the two cutters so that when they mark they just fit the width of the chisel; then set the head of the gauge $\frac{11}{16}$ in. from the inner cutter, and run it over the positions of the mortises and tenons, on the stiles and rails, and also on the bars. Be careful in running the gauge to work from the marked face of your framing, as if, by any chance, you mark off a mortise or tenon from the back, it will cause you some vexation when you come to put the window together. Take an ordinary marking gauge; set it so that it will mark *exactly* in the centre of the mortise on the bars, and mark off each with it; this centre mark is shown at C in Fig. 5. You have now to take a $\frac{1}{4}$ in. chisel and cut out these mortises with it, but carefully observe that in the upright bars it is the mortise next the front edge that is taken out, while in the cross-bars it is that next the back edge.

This may seem a little mystifying, but it will become quite plain to you when you come to put the framing together. The stiles and rails you will have no difficulty about, as they are mortised and tenoned in the usual way, which I assume that you have already mastered.

So far only the ordinary tools that are in daily use have been required for the work; now you have reached a stage when tools of a special nature must be brought into play (or shall we call it "work?"). These tools are a pair of sash-planes and templates; various shapes of mouldings are run on sashes, but the commonest, if not the easiest, is the "Gothic," and I will suppose that to be the style used in the present case. The templates supplied with the planes are two in number, and are used to guide the chisel in mitring and fitting the mouldings of the sash, the single template being used for the framing, and the double one, previously referred to, for the sash-bars. A $\frac{5}{8}$ in. sash gouge is also requisite for this fitting work. Besides these planes, you require a "sash fillister" for making the glass check or rebate on the framing, and a "sash-bar," or "astragal fillister," for that on the bars. These tools having been procured, and well sharpened and accurately set, you are ready to commence work with them. But before you start I think I had better describe a little arrangement that will be of the greatest service in holding the pieces of wood steady while you are working upon them. Take two strips of $\frac{5}{8}$ in. wood, about 2 in. wide and 3 ft. long, place one of your stiles on the bench with the end against the stop, nail down one of the strips of wood close to the back of the stile, then nail down the other piece at the front, but in such a way that a third piece of a wedge shape may be driven between it and the stile, and so hold it firmly in position.

Take a stile, lay it on the bench, drive the wedge home, set your sash fillister so that it will just clear the back edge of the mortise, and run down until the rebate is *exactly* $\frac{3}{16}$ in. deep. On looking at the sash-planes, you will find them marked 1 and 2. No. 1 is used to run down with, and No. 2 takes off

a shaving or two more, and puts a finish to the moulding; thus you will see that you may let No. 1 take off a moderately thick shaving, but No. 2 should be set very fine, and kept as sharp as possible. It is best, before running No. 1, to take off a shaving or two with the jack-plane from the sharp angle of the wood, otherwise No. 1 plane is apt to wear too much in the centre. Do the rails in the same manner as the stiles, and then take the bars in hand. For the bars you will require to make a wider wedge, so that you can secure them firmly on the bench, *back* edge uppermost; set your bar fillister so that it will form a rebate of equal depth on both sides of the bars, and run it down till it is of the same depth as the rebates on the framing. Fig. 6 shows the sash-bar, in section, fixed on the bench and rebated.

To run the moulding on the sash-bar you will require to make a special apparatus of the nature shown in Fig. 7, where it is shown in full size. The easiest way of making the back or grooved piece is to form it of three thicknesses of wood and fix it to the lower board, which should be of 1 in. wood, with screws. The back piece should be put on so that when the bar is in its place its front edge will be flush with the front edge of the board, along which the fence or guide of the plane has to work. Fix this "running board" to the bench with a screw nail at each end, place the bars on it, and run the planes, first on one side, then on the other, taking particular care in running down the second side to hold your planes very steady, as when you run down without caution you are almost sure to spoil the front edge of the moulding where it merges into that of the other side.

All the rebating and moulding being done, you can begin to mitre and fit together. Take the rails first, and with the single template mitre the moulding at each end, keeping the template to the innermost of the three marks (C), which is still visible on the top edge. After mitring, take the sash, gouge and cut down about 1 in., clearing the corner next the tenon with a narrow chisel; turn over the rail, and with a $\frac{1}{2}$ in. chisel cut down a groove $\frac{5}{16}$ in. deep on the end of the rail till it meets the tenon (A, Fig. 8). This groove is to allow of the fitting in of a corresponding projection on the stile which serves to steady the joint. Fig. 8 is a drawing of the end of a rail, showing the way in which the fitting as described is done.

The stiles are then taken, and with the template the "list," or small piece that is between the mortise and the moulding, is cut down to where it touches the top part of the moulding, and $\frac{1}{4}$ in. from that the moulding is cut down on the bevel, and the piece taken clear out to the end of the stile. It is almost impossible to describe in writing the mode of doing this, but a study of Fig. 9 will show how it is done, and in practice you will easily comprehend the way to do it.

The two upright sash-bars are now mitred, using the double template. Let the mitre come clear to the outer edge of the moulding, and if correctly done from both sides of the mitre the cuts should meet exactly at a point, but leave a little wood towards the inner side, to prevent the bar breaking (Fig. 10). Mitre the ends as in Fig. 11. Take the cross-bars, cut each of them into three pieces exactly through the centre mark (A) on the mortise, and mitre the ends, as in the other bars. Fig. 12 is the end of a bar cut and mitred for the crossing.

Run a fine hand-plane along the flat piece between the mouldings and rebates on each of the pieces of your sash. One shaving is enough, as it is merely to give a clean appearance to the job, which, no doubt, will have a few finger-marks about it; and nothing looks worse on a piece of new woodwork than finger-marks—in fact, they stamp the worker as a sloven; and I have been in shops where, if a finger-mark was found on a job when it left the bench, a severe wigging from the foreman was the result, with perhaps the sack, if the workman persisted in leaving the "marks of the beast," as they were called, on his work.

Plane up a piece of wood, $\frac{1}{2}$ in. thick, and cut out of it some wedges. You only want sixteen, but you had better cut a few more, in case of breaking any in the driving. These wedges should be about 3 in. long, $\frac{1}{2}$ in. wide at one end, tapering to $\frac{1}{8}$ in. Put a point on them with a chisel (Fig. 13). Be careful to cut your wedges square, as if they are not cut fair, they are apt to twist in driving, and will split the framing. Make also four round pins, $\frac{5}{16}$ in. diameter, and you are ready for cramping up the sash, for which purpose clear everything off your bench, and lay two pieces of wood across it. The size of these pieces is immaterial, but of course they must be longer than the sash is wide—about 3 in. by $1\frac{1}{2}$ in. stuff is a suitable size. See that they are out of twist with each other when lying on the bench; if they are not, you must level them up until they are, by putting pieces of wood under the ends where required. If these bars were lying twisted, your sash would be twisted when cramped up.

Put the long sash-bars into their places in the rails, then put on the stiles, not driving them close up until you insert the pieces of the cross-bars. When they are in place, knock the stiles close, and lay the window on the pieces of wood on the bench, cramping up the joints with a joiners' bench cramp, and using thick white lead on the tenons and wedges instead of glue, which is unsuitable for work that is exposed to the influences of the weather. The stiles should be cramped up and wedged, and holes bored through stiles and tenons about the position marked A on Fig. 9. Into these holes the pins should be driven, after dipping the points in white lead. Now turn the sash and cramp up and wedge the bars—they do not require pinning. In doing this, you must be careful not to squeeze too tightly with the cramp, or you may bend or break some of the bars. Just put on enough pressure to bring the joints well together, and drive the wedges in evenly at each side, to avoid twisting the bars.

Two things must be attended to in the operation of cramping up. One is that the cramp must be applied in such a way that the stiles are not twisted up or down from the rails. If you apply the cramp too low you will twist them downwards; if too high, upwards. To avoid this, try a straight-edge, or the back of a square, across stile and rail, and raise or lower your cramp as required. The other matter is the keeping of the sash perfectly square while cramping. This is best done by trying it across from corner to corner (diagonally) with a rod. When the distance between the opposite corners is exactly the same, the sash is square, and care should be taken to keep it so while cramping.

Cut off the projecting ends of the wedges and pins, and plane up neatly on each side, being careful when doing the outside not to break away the thin piece between the rebates on the bars. Your sash is now finished and ready for fitting into its place, until which operation it is best to leave on the stumps of the stiles, and cut them off when doing the fitting.

When you have made a sash similar to that described, and mastered the little difficulties and intricacies of the various joints and mitres, you will have learned a valuable lesson, and one that will enable you to attempt with a greater chance of success the more intricate forms of windows.

The greenhouse builder, whose requirements in the way of sashes do not often include those with cross-bars, can, by following these instructions, and leaving out the horizontal bars, construct his side-lights to whatever dimensions he may choose; while in another paper I will endeavour to show him how to make his roof-lights, they requiring a different treatment in the matter of the sole, to allow of the water running off.

In common greenhouse work the use of the sash-planes may be dispensed with, and the inner edge left square, or chamfered. Of course, in leaving square edges you will have to allow for them in cutting the shoulders of the tenons, so that the marks C, C, in Fig. 3 will be those to square over on the face side of the rails for the shoulder.

When a number of sashes of the same size are to be made at one time, all the stiles may be laid on the bench, and set out at once by squaring across your marks on the top edge, then turning over and squaring them across on the back. While setting them out in this way, a sash cramp is generally employed to hold them together and prevent slipping, and also to aid in turning them over. The top edges of the rails are squared over in the same way, and the bars, if any, are held by two sash-cramps, and not only marked off, but shouldered and tenoned at one operation, after which the cramps are taken off, and the mortises squared over and worked out. This method saves much time in dealing with the various pieces singly.

In closing these brief instructions, I would again urge upon the worker the necessity for exactitude in all his manipulations—let him go slow until he is sure of his ground, and has quite mastered the details of the work. Applying the words of an old joiner I once knew, let him "First learn how to do a thing thoroughly, then—but not till then—how to do it quickly."

## HOW TO MAKE A WEATHER GLASS.

BY J. GEO. LISTER.

INTRODUCTION, REMARKS ON MERCURIAL BAROMETERS—PRINCIPLE OF THE GLYCERINE BAROMETER — APPARATUS REQUIRED — DETAILS OF CONSTRUCTION—FITTING UP—USES.

THE mercurial barometer, though the most perfect instrument of its kind, and therefore the one deservedly used as a standard instrument for measuring variations of atmospheric pressure, is by no means an instrument easy of construction by an amateur. In the first place it is very difficult to procure glass tubing, which, whilst being of the requisite cheapness, shall be at the same time both strong enough and of sufficient equality of bore throughout. Again, it is one thing to fill a tube with mercury in an ordinary way, it is quite another to so fill a barometer tube with pure mercury that it shall contain no

air ; and, finally, no one but an expert knows what it means to make a glass tube "chemically" clean. The majority of persons who use a barometer do so for one purpose only—viz., to ascertain probable changes of weather in this very uncertain climate of ours. It will therefore be our purpose in this article to show how a "weather glass," but not a barometer, can be made which shall serve all the general purposes of the more expeusive instruments.

It was discovered by Boyle and formulated by Mariotte, that when a gas is subjected to pressure, the volume occupied is exactly inversely proportionate to the pressure upon it—*i.e.*, if we increase the pressure we decrease the volume, and *vice versâ*. Now this law has been applied to obtain a knowledge of the state of the atmosphere by observing the changes of volume of a gas—*e.g.*, air in a closed vessel.

Now as to apparatus. We shall require the following, and appended will be found the average costs. Glass tube about 4 ft. long, and what is known as No. 3 cane, which is the size shown in Fig. 1. It has an external diameter of $\frac{3}{16}$ in. ; cost, about 3d. A glass bottle of about 8 oz. capacity, cost, about 1d. ; a composite candle, $\frac{1}{2}$d. ; cork for bottle ; a piece of paper, about 4 ft. long. This can be obtained at any draper's, gratis—it should be about 1 in. wide ; a few magenta crystals, cost, 1d. ; wood charcoal, 1d. ; about one quarter of a yard of flannel, cost, 3d. ; one piece of wood, 4 ft. by 1 in. by $\frac{3}{8}$ in., cost, 2d. ; and about 2 ft. of $\frac{3}{8}$ in. by 4 in. timber, cost, 2d. ; and, finally, 2 oz. of best glycerine, cost, 2d. Total cost, 1s. 3½d. For this amount we can make an instrument which will be of far more use as an indicator of coming weather than many a barometer costing more than twice as many shillings as ours does halfpence.

Now as to details of construction. Fill the bottle with glycerine about one-quarter to one-third, which has had one or two crystals of the magenta dissolved in it. This is to render the glycerine more readily visible. Next, thoroughly clean the glass tube. This can most readily be done by taking a small wad of cotton-wool and tying it in the middle of a string about 9 ft. long. Pass one end of the string through the tube and pull the wad through after it. Then reverse the operation. Do this two or three times and the tube will be found bright, clean, and *dry*, which is a great consideration. Next bore the cork, making the hole much less than the outside diameter of the tube. This can be done either by the careful use of a gimlet or a hot knitting-needle. The hole must then be enlarged until it is just smaller than the tube. Now push the cork carefully into the neck of the bottle, and having rubbed down the end of the glass tube on a little emery-paper, pass it with a gentle spiral motion through the cork and down into the bottle till the bottom end dips under the surface of the glycerine about $\frac{1}{2}$ in. Take next the candle, and, having lighted it, allow drops of the "wax" to fall all over the cork, and having heated a wire in the fire, pass it all over the cork so as to thoroughly melt the wax and allow it to run into the holes in the cork. Repeat, and when the cork will absorb no more, completely cover the whole lower end of the tube, the cork and the neck of the bottle with droppings from the candle. If this be properly and carefully done the tube will fit into the bottle quite air-tight. Now place the bottle on the floor, taking great care not to break the joint, and, having filled the *mouth* with air, blow a *few* bubbles into the bottle (see Fig. 2). Remove the mouth, and the air which has been compressed within the bottle will, to equalise the pressure, drive the glycerine about half-way* up the tube (Fig. 3). To make the scale, take a piece of the ribbon paper as long as the tube and divide it into 100 equal divisions, and gum this on to the strip of board of the same size, plus a small piece at the lower end where the wood scale is to fit into the box containing the bottle.

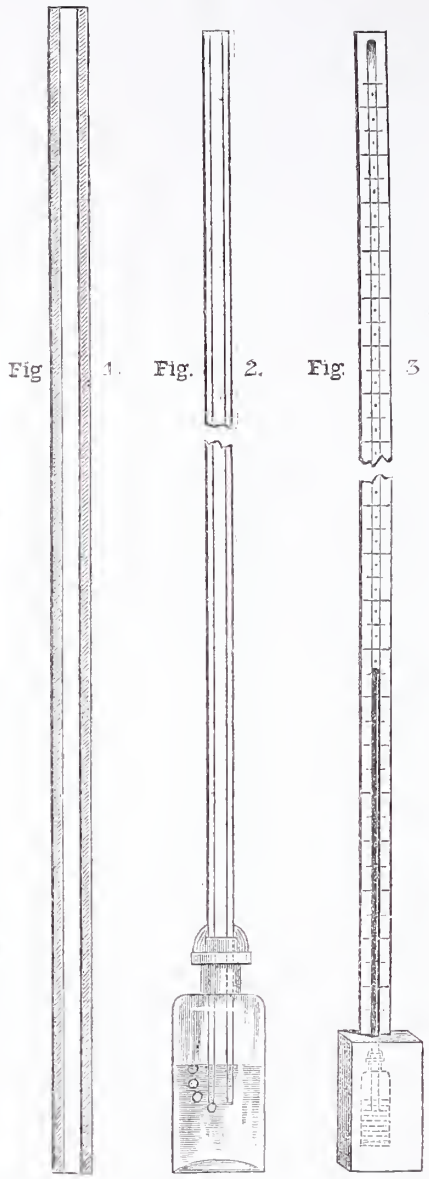

Fig. 1.—Glass Tube : ¼th of Actual Length, but showing Actual Diameter of Tube. Fig. 2.—Illustration showing Compression of Air and Method of filling Tube. Fig. 3.—Instrument Complete with Scale and Box.

Our next proceeding will be to arrange for the protection of the bottle from atmospheric changes of temperature. This is done by cutting the flannel into strips about 1 in. wide, stitching these into one long strip and binding this closely round the bottle spirally from top to bottom. Now make of the remaining timber a small box about 3 in. square and 2 in. longer than the bottle. Place in the bottom of this a mixture of coarse sawdust and broke charcoal in a layer about 1 in. deep, and c this place the bottle. Fill up the box wit the same mixture, completely covering th cork. Fix the scale with its back into th lid and slip this over the end of the tub and secure the top with screws—not nails, a these might cause the joint to "spring Secure the tube to the scale by one or tw small staples or pieces of wire.

Finally place on the top of the glycerin in the tube a drop or two of paraffin oil this will effectually prevent the glycerin absorbing water from the air, which it very liable to do, and loosely close the en of the tube with cotton wool, and o weather glass is complete.

To USE.—Place the "glass" on a brack (in some place where the sun does not shin and where the temperature is fairly co stant) about 3 ft. from the floor, and car fully observe its behaviour for a few day It will be found on the approach of a chang in the weather, and hours before a me curial barometer show any indication, tha the glycerine begins to rise, often seven inches, indicating wet or wind ; or fall, ind cating fair weather. After a few day comparison with itself the glass will b found one of the most faithful of "weath prognosticators."

* When "setting" the glass it will be advisable to consult a mercurial barometer—one of the many public ones suffices, or the weather reports in any newspaper—and if the mercury stand very high, the glycerine should be made to stand low, and *vice versâ*.

## WIRE-WORK IN ALL ITS BRANCHES.

BY JAMES SCOTT.

### RAT-TRAPS.

No one will feel inclined to deny that of a the pests, the torments, and depredation of which we are frequently exposed to, ra must be classed as the most formidabl Man's ingenuity has been called into exe cise to endeavour to eradicate this nu sance, and the devices, passing under th general name of rat-traps, are numerous an various. The commonest pattern is the on which I have taken for our consideration, an is shown in Fig. 94 (see page 485). Som may say that this kind of article is fallin into disuse, because the vermin which it most desirable should lose their liberty b its aid are possessed of sufficient intelligenc or reason (although some would try t assure us that it is but instinct) to foresee the calamitous results of their entering th "freehold" construction, and endeavourin to extract the delicate (?) morsel from th interior thereof. But, withal, it is an ex ceedingly useful trap ; and, in addition, is comparatively cheap to purchase, and will not be found difficult to construct b anyone desirous of so doing, who will giv his attention thoroughly to my detailed description of it.

Referring to my above remarks on it usefulness, I must say that when introduced for the first time among a colony of thes detestable creatures, it may safely be relied upon that a few at least will be captured This is decidedly most advantageous ; fo rats are, I am given to understand, ver prolific, and consequently increase immensely in numbers in a comparatively short period I will now press forward to the particular of their manufacture—not of the rats, bu of the traps.

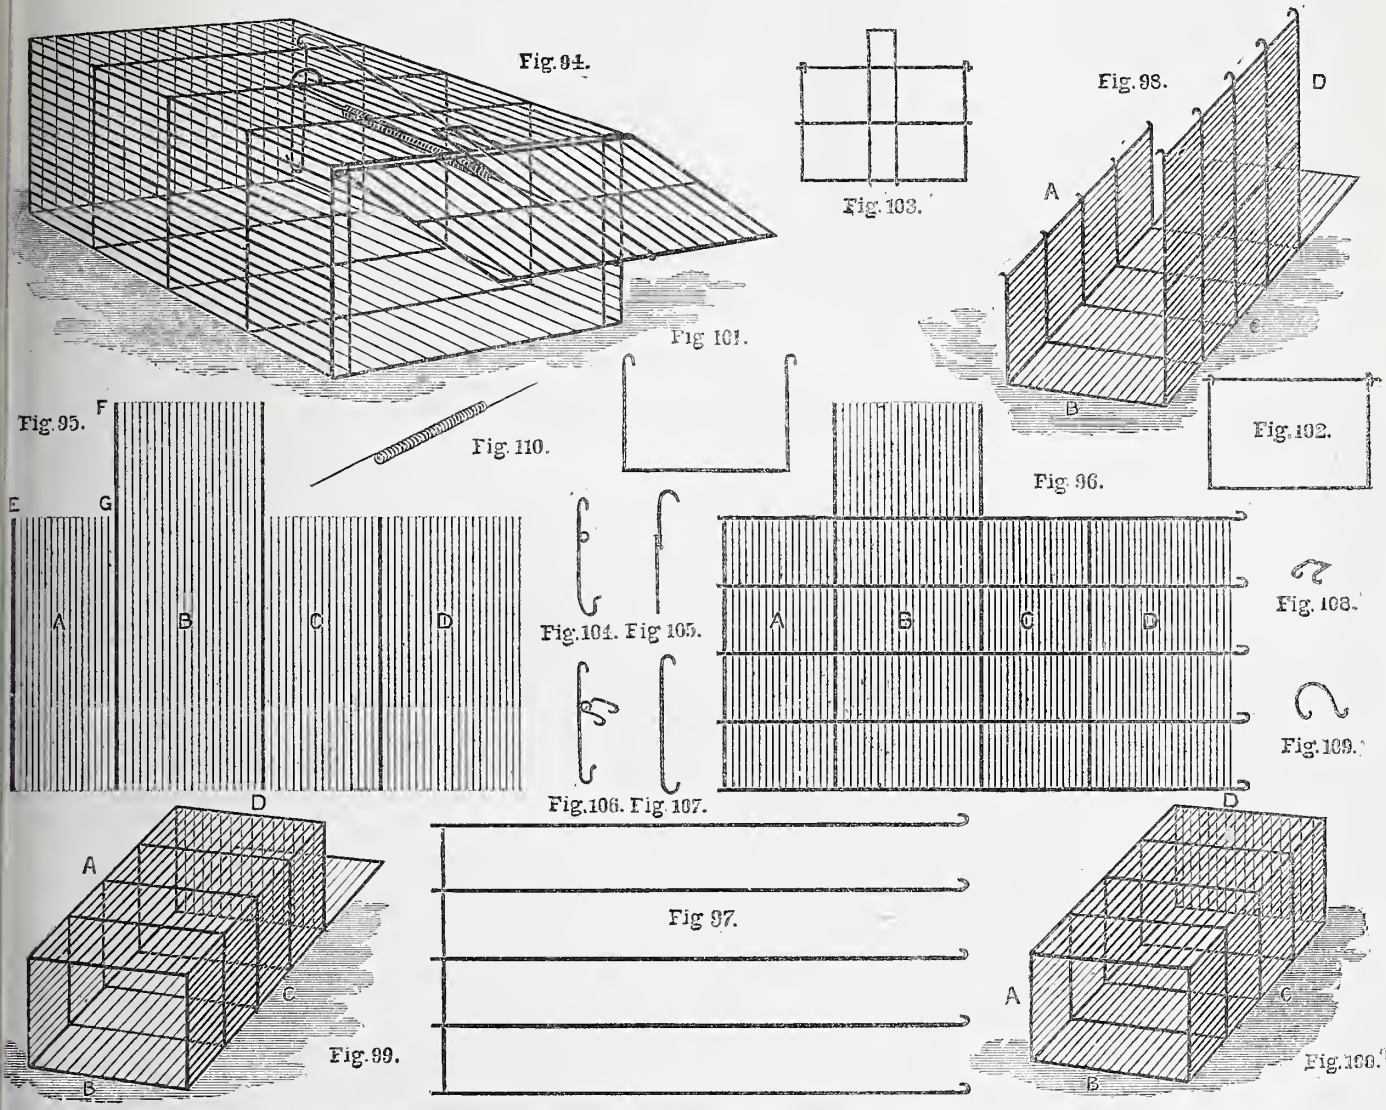
A long strip of tin, or other metal, has a number of holes through it. It is fixed t the bench by being stapled, or secured in some other manner, one end of it being on the left-hand side of the worker, and th other end at the right-hand side. Three of the holes are rather larger than th

mainder, for certain reasons which will be ade clear to the reader in my future re-arks. This simple appliance is called a de, and I have spoken of it in a previous per.

In beginning a trap of the size noted in g. 94, the wires are laid as shown in Fig. . These are supposed to be laying hori-ntally. The front end of each of them is nt into the form of a hook. The tenth, enty-fifth, and thirty-fifth wires, counting m the left-hand side, must be of a stouter uge than the remainder. They are after-portion of the wires adjacent to the latter to project in front of the slide. Upon them is afterwards placed the frame. I will proceed to describe this. It is shown in Fig. 97, and consists of five wires of sufficient length each to cover the whole of the wires in portions A, B, C, D (Fig. 96), and each parallel to the others and at equal distances apart, with hooks at their right-hand ends. They are turned over on to a bar at the left-hand side.

The lower wire of this frame is laced to the whole of the wires upon which it rests frame within a short distance of the ends of the wires in portions A, C, and D (Fig. 96), which latter are then turned over on to it in the usual way.

Thus far, the work appears as in Fig. 96. The bending now takes place. It is still supposed that the work is laying flat upon the bench. Portion A (Fig. 96) is then bent upwards into a perpendicular position, and portions C and D are also bent thus both together (Fig. 98). Portion D is still further bent, in a horizontal direction this time, bringing its exposed side against the exposed



**g. 94.—Rat-trap Complete. Figs. 95, 96, 98, 99, 100.—Progressive Diagrams, illustrating the laying out of the Wires, fixing of the Frame, and Ultimate Bending. Fig. 97.—The Frame. Figs. 101, 102, 103.—Progressive Diagrams, illustrating the Construction of the Door. Fig. 104.—The Bait-hook (Side View). Fig. 105.—The Bait-hook (Front View). Fig. 106.—Bait-hook with Link Wire (Fig. 108) attached. Fig. 107.—One of a Pair of Drop Wire Runners for Front of Cage. Fig. 108.—The Link Wire for Bait-hook. Fig. 109.—Handle. Fig. 110.—Spring.**

ards bent in certain ways; but I must rst name their parts. A and C will be the des; D will be the top; the larger part of will be the bottom, while the smaller por-on of it (that which is above the remainder f the wires contained within the space F G -Fig. 95) will form one end. One end will e left open to receive the door. All these ires are then placed through the respective oles in the slide. I do not show this stage f the process in any of my diagrams, as a rawing would appear but a confused mass f lines; therefore I must ask the reader to ollow my description as closely as he can.

These wires, then, are pushed through he holes, allowing but the hooks and a (Fig. 96) at a point just above the hooks. It, when this is completed, is drawn exactly underneath the front hooks, naturally carrying frontwards the other four wires composing the frame, and the front hooks are then squeezed over on to it. Of course, it will be seen that it cannot conveniently be fixed under the hooks, and there laced, in the first instance.

The work at this stage is drawn further frontwards through the slide, and the second wire of the frame laced in its position. The third, fourth, and last wires are similarly treated, care being taken that they are laced exactly parallel to each other. These operations should bring the last wire of the side of portion A (Fig. 99). It will be now understood for what reason the hooks are upon the right-hand end of the frame (Fig. 97). They are, of course, brought, by this bending process, close up against what was the exposed side of portion A, over which they are then turned and squeezed down. The final procedure to complete the skeleton of the trap is the bending upwards of the wires in the further part of the portion B, which have all the while been laying horizontally, bringing their ends in direct contact with the end of portion D, over which they are then turned. Therefore, the wires composing this part of portion B must be in length, when they are turned over, equal

to the width of each of the portions A and C separately. What I mean can be seen by a glance at Fig. 95; the part F G must be a trifle longer than the part E G, the extra length being for purposes of turning over. To strengthen the end when thus far finished, a single bar is laced or tied upon the outside of it, across the middle.

The door is the next thing to attend to. For this a frame is made. I will deal with it as with the other parts—progressively. First there is a bent wire, as in Fig. 101, the hooks of it being supposed to be bent *away* from the reader, which can hardly be properly shown in a small sketch. Immediately underneath the hooks is a cross-bar, turned over from the front on to the sides of the first wire (Fig. 102).

In the middle, when thus far complete, is an upright wire, bent in a similar, but reverse, manner to that in Fig. 101, but being much narrower and a little longer than that wire when so bent. Previously, the required number of wires must have been placed in the slide in the same manner as the larger piece of work, having, likewise, hooks in the front. My foregoing instructions will apply equally to this part of the trap, the wires being laced and turned over on to the frame. I must mention, however, that two or three wires in the middle must be somewhat longer than the remainder, and be turned over on to the longer part of the frame. This last part is laced on to the rest when the lacing takes place, and a double stitch is usually given for purposes of strength, where the longer part of the frame comes in contact with the cross-pieces.

The fixing of a middle bar is the final performance to complete the body of the job. It is laced securely across the front of the door, and tends to strengthen it. The door, thus ready, is attached to the body of the trap by having its top hooks squeezed down over the front top wire of the body in such a manner that the door may work freely up and down. I will leave the fixing of the spring until last.

The bait-hook is the next part added. This is shown in Fig. 104. The top hook upon it is bent at right angles to the lower hook (Fig. 105). Through the eyehole is passed a small bent wire (Fig. 106), which latter has a hook at each end of it. The hook is then passed through the top of the cage, and the small wire (Fig. 108) secured to the middle cross-wire of it by means of its hooks being squeezed down upon it, and further by its being tied to the various wires it touches.

The handle is fastened to the same wire as that to which the bait-hook supporter is attached, but the latter holds the hook at a distance from the handle, and therefore in no way interferes with it. The handle is merely a bent wire with a hook at each end (Fig. 109), by which it is secured to the wire above-mentioned across the cage.

A single wire is bent over the long top wire of the door, outside, so that it may work freely, the further end of it being quite straight, as most people know. This wire, when its loose end is fixed under the bait-hook, retains the door as in Fig. 94, and the slightest movement of the hook displaces it, and consequently releases the door.

A drop wire is attached to the front of the cage, with the view of preventing any unpleasant rodent who may have been unfortunate enough to be entrapped from making his escape. Wires, shaped as shown in Fig. 107, are secured, one at each end, to the front of the body, in a direction continuous with the latter. Over these is slipped a wire, in length the same as the width of the cage, having an eyehole at each end, so that it may be easily moved upwards and downwards. When the trap is set with the desire of catching a victim, the drop wire is drawn to the top of the cage; and the reader will see clearly how, when the door has closed, the wire will drop to the bottom, over the front of the door, and preclude any possibility of its being opened from the interior by an occupant.

The process of springing is now reached. I have elsewhere described how to form a spring. A good strong one will be necessary for this work. One end is fixed to the second or third wire of the top of the cage, and the other end fastened to the cross-wire of the door. It must be in an unstretched state when this is done. Two springs, one at each side, might be fixed; but it is usually quite sufficient for purposes of strength to have but one.

Particulars as to sizes and gauges of wire used in connection with various articles I intend to describe will be given in another number. This will prove more convenient for the reader.

## PRACTICAL PAPERS FOR SMITHS.

BY J. H.

THE WORKING OF STEEL—DIFFERENCE BETWEEN WROUGHT IRON AND STEEL — HEAT FOR WORKING — DIFFICULTIES OF WORKING — OVERHEATING — MODE OF HEATING — BLUE HEAT.

I AM now going to devote two or three papers to a very important and difficult section of the smith's art—namely, the manipulation of steel. There are larger quantities of this material used now than formerly. A good many questions appear from time to time in WORK relative to the subject. It is one that embraces a very wide range of operations; I shall therefore devote this article to the general consideration of the working of steel, and afterwards write in some detail on the special processes of welding, hardening, and tempering.

*Wrought Iron and Steel Contrasted.*—There is, as regards chemical composition, very little difference between wrought iron and some of the Bessemer and Siemens mild steels. But there is a very essential distinction between them when brought to the test of working. Wrought iron is not perfectly homogeneous; mild steel, like the crucible or tool steel, is of the same character throughout. This difference is due to the difference in the processes of manufacture. Wrought iron is never at any time during the process of its puddling in a state of absolute fusion. It is simply brought into a pasty condition, like a lump of dough. The fluidity of cast iron is mainly due to the presence of its carbon, and in a lesser degree to its sulphur. These are removed from the iron in the processes of puddling; and one important result is this of non-fusibility at the temperature at which it is found best to work it. In order to render this material, therefore, as homogeneous as possible, the pasty mass is hammered under steam hammers or tilt hammers, and is passed beneath squeezers of different types, is cut up again and reheated, and the operation of hammering, squeezing, and rolling repeated, the quality of the iron improving with each repetition of these operations. These sets of operations will be repeated three or four times in the case of good merchantable iron, and it is the cost of fuel and labour involved therein which renders wrought iron so much more costly than cast iron. After the last piling, re-heating, and hammering processes have been gone through, the iron is run between grooved rollers of diminishing sizes, to impart the final sectional forms to the bars or plates required for the use of the smith and boiler-maker. But it is because of the absence of fusion that even in the best wrought iron some of the oxide or scale, and some of the mechanical impurities originally present in the iron, or taken up in the process of puddling, become inextricably entangled with the bars, and remain therein, causing the iron to become spilly, and to develop incipient fracture when wrought into structures.

*Lamination absent from Steel.*—From this lamination the Bessemer and Siemens steels are free, for the simple reason that during the process of fusion all scale or oxide has been eliminated. And this is one reason why the mild steels have superseded wrought iron largely in boiler-makers' work, and in some smiths' work, especially cranks and similar structures, where lamination would be fatal to strength and durability. The best wrought iron can never be entirely depended on for absolute homogeneity. But for the average work of the smith it holds and must long hold its own, because of its ductility, weldability, and the general ease with which it can be fashioned into intricate forms.

*Homogeneity of Steel.*—Steel being homogeneous—that is, having no grain—is eminently adapted for the forging of light and delicate work, where strength, rigidity, and lightness are required in combination. It is therefore specially adapted for model work and for the finer portions of mechanism, and for those where strength is essential.

*Heat for Working.*—After the absence of fibre, the next cardinal difference between the working of wrought iron and of steel is this: that while wrought iron can be worked almost at the fusing point, steel cannot be worked beyond a full red heat. Moreover, each different sample of steel seems to work best at a particular temperature, differing from that of other samples.

*Polish.* — Another point in favour of steel is that it takes a much higher polish than wrought iron, and is therefore better suited to work where good finish is necessary.

*Capacity for Hardening.*—Steel owes its chief value, however, to its capacity for hardening and tempering. A regular gradation in hardness is thus obtainable, rendering it suitable for every possible requirement.

*Capability of Working.*—Whether steel is more troublesome to work than iron depends partly on the nature of the forging and partly on the quality of metal. For small model work, steel is by far the best, because there is no grain to open out, besides the facts before mentioned of superior rigidity, and so forth. In large and heavy forgings, on the other hand, there is no advantage to be gained on this score. In forgings, again, of moderate size and thin sections, on which a good deal of work has to be done, forging in steel becomes more expensive than forging in iron. For as steel has to be worked at a lower temperature than iron, a larger number of heats must be taken in the former than in the latter. For the same reason the various operations should be

performed more rapidly while the steel retains its heat.

*Capability of Welding.*—There is more difficulty in welding steel than iron. But the difficulty is largely of an initial character, being due to the differences in separate samples of steel. Once the best welding heat for any bar of steel is known, then there is no more trouble experienced in welding pieces from that bar. Sand alone is used as a flux for welding iron; for steel a mixture of sand and common salt is better.

*Opinions re Working of Steel.*—There is not so much unanimity of opinion among workmen as to the working of steel as there is in regard to the working of iron. The practice of allowing steel to soak in the fire, approved by some, is denounced by others. The temperature to which steel can be raised without burning it is a matter of dispute. The practice of hardening and tempering opens up a vast and unlimited field for discussion. The reasons are not far to seek; steels vary much more in quality than wrought iron, and since the peculiar value of steel is due to most minute chemical and molecular composition, and as slight and sudden alterations in temperature are sufficient to entirely change their arrangement, it is easy to understand why, though not how, they should influence the practical working of the material. Partly, too, because of these differences and consequent differences in treatment demanded, are some makes of steel considered superior to others. Thus, a man may have been accustomed to work in one quality mainly, and having adopted certain modes of treatment of that with the best results, and finding the same modes do not give equally good results with another quality, he too hastily condemns the latter, when in reality the fault lies at his own door. It cannot be too strongly insisted on that every new bar of steel should be first worked tentatively, in order to discover the best heat and the best way to work that particular bar. Unless this is done, frequent failure to obtain the best results will follow.

*Upsetting Steel.*—The practice of upsetting steel is deprecated by some. But if the steel is of good quality it will upset just as well as iron.

*Overheating.*—Steel must not be overheated, or it will become burnt. But it should be made as hot as the metal will safely bear. A higher temperature can be used on steel required for large forgings than for steel used for cutting tools, and for light work generally. A piece of burnt steel will crumble to pieces under the hammer as though it were cast iron, and will show a coarse granulated fracture. There are, however, degrees in burning—it may be burnt slightly on the surface, so slightly that it does not fracture, or, if fractured, does not show this coarsely crystalline structure. Yet its quality for cutting instruments will, nevertheless, be sensibly impaired. The temperature at which overheating occurs varies, of course, with different qualities. If scales form and fall off, the steel is, as a rule, overheated. It is then almost impossible to restore it to its pristine quality. If not burnt very badly, a good hammering on the anvil will improve it considerably. There are also various physics employed by tool smiths. They mix various ingredients, and keep these by them for use. The following is one:—Mix together two parts of pitch, two of train oil, one of tallow, and a little salt. Plunge the metal at red heat into this two or three times in succession.

*Mode of Heating Steel.*—The smith uses the forge-fire for heating any steel for forging. For hardening and tempering he only uses the fire in the case of large work; small work is heated on a bar of iron first made white-hot in the fire, or special furnaces are used. The temperature of small pieces of work can be regulated better on a bar of iron than in the fire. When steel is heated in the fire the blast is put on very sparingly, and the heat also is kept as low as it is possible to forge at. Moreover, the steel is allowed to remain in the fire sufficiently long to become of the same temperature throughout, but "soaking," as the saying is, beyond this is dangerous.

*Uniform Heating.*—Steel, even more than iron, should be turned around in the fire to keep the heat uniform. The blast should be slackened after the edges have become red-hot. A full "cherry-red" is usually considered the proper heat for forging. But this expression is rather vague, and the temperature, as we said before, will vary with different qualities. Hammering should not be continued after the steel has lost its redness. It is injured by hammering at a blue or blue-black heat.

*Blue Heat.*—Smiths and boiler-makers know that there is a temperature in steel corresponding with what they term a "black heat"—a heat at which it is not safe to work it. A number of experiments have been made by the Steel Company of Scotland, and by Mr. Strohmeyer, upon steel in this condition, and they fully bear out and emphasise the rule-of-thumb knowledge of the practical man. At the works of the Steel Company of Scotland forty-eight plates were taken, and strips cut from each. Half the strips were bent cold to an angle of 180° round a bar of a diameter equal to twice their thickness, and all stood the test. Corresponding strips were heated in boiling tallow, and bent at that temperature, and everyone cracked before the bending reached 180°. Other experiments showed that a plate heated, and allowed to cool, suffers no diminution of strength, but that if while cooling, and during the period while it is at a blue heat, any hammering or bending is done, it will be found when cold to be seriously injured. Mr. Strohmeyer found that while a test strip bent cold would stand from twenty to twenty-six bendings before cracking, if it was bent once while at a blue heat, and allowed to cool, it broke afterwards with very few bendings. The blue heat corresponds with any temperature between about 470° and 600°.

In my next paper I shall write of the various classes of commercial steel, and of the art of welding the mild steels. A subsequent paper will be devoted to the hardening and tempering of the high carbon steels.

## IMPROVEMENTS IN HARNESS.

BY J. C. KING.

### Top Hame Fastenings.

There is plenty of room for improvements in harness, but they must come from users who know what is an improvement. Harness-makers, especially wholesale firms, stick to old devices and methods, so that their feeling is against anything that requires any extra supervision of work in a factory.

Doubtless it is the piece-work system of fixed prices and methods that has prevented many essential improvements being offered to the public in harness.

The present method of fastening the hames to horse-collars is by a strap, top and bottom, into two eyes to each hame, which hames may be described as the yokes of the collar to which the traces are fixed.

For pair-horse harness, chains are used at the lower ends of the hames, and a strap at the top of the collar to draw together and secure the hames in their places.

This seems to have been the plan for ages, and serves the purpose well.

In farm-cart harness it is a leather thong, which laces through holes in wooden hames. In waggon or van and town-cart harness, a buckle is used for the strap.

The same plan of a buckle is used in all pleasure vehicle harness, from the State carriage harness down to the costermonger's barrow harness.

In one essential particular it is unsatisfactory. The tail end of the strap is a loose

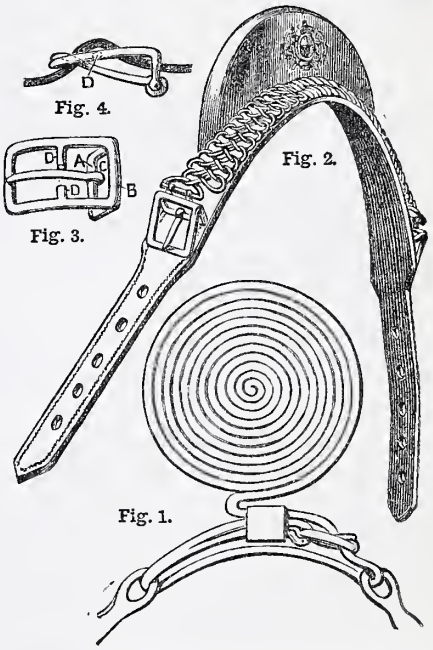


**Fig. 1.—Four-in-hand Top Hame Strap. Fig. 2.—Read's Arrangement of Top Hame Strap. Fig. 3.—Improved Buckle seen from above. Fig. 4.—Ditto, Side View.**

flapping point, that makes the harness look as if coming apart here.

The four-in-hand coachmen have tried to give a decorative turn to this point by winding the end of the strap into a miniature target, but it is apt to come uncoiled on a journey: it cannot be considered an ornamental device, as represented by Fig. 1.

The only successful plan yet adopted was patented by the late Mr. Thomas Read. This method in a simple way changed the upper strap into a combination of chain and strap, with two buckles instead of one; and the buckles were made in a peculiar form, with double heel-bars, by which the points of the ends of the straps were put out of sight under the chain when buckled up. Fig. 2 gives an idea of the buckles and the highly ornamental strap, with "housing" for monogram or crest. Although the article "Buckle" is not treated in some encyclopædias—and in one it is said that the buckle was introduced by Charles II.—discoveries in the ruins of Silchester have brought to light a buckle closely resembling the double-heeled one of the patent hame fastening. To ensure the

effectiveness of this highly ornamental hame-chain, a special buckle had to be invented; without this useful security the hame-chain would be useless.

No form of buckle out of some 150 different sorts now made would serve the special purpose of holding at once a chain and a strap, and allowing the point of the strap to be hidden away somewhere; for, useful as is the point of a strap, it is not ornamental either coiled up or dangling up and down with the motion of a horse's shoulders.

Some old and prehistoric buckles were looked over in the museums of England and the Continent. They yielded interesting treasures for survey, but perhaps the most interesting were those excavated from buried cities and tombs, showing the advance in metal working ages ago: notwithstanding the absence of the word "Buckle" in some encyclopædias, and the assertion of one that they were brought into England as fastenings for shoes by Charles II.

The buckle-makers seemed to know less about the uses of buckles than anyone else. The difficulty was got over by having two heel-bars, as shown in Fig. 3, A, for the chain, and B for the strap, with a space, C, between to receive the strap point. How was the lower heel-bar, A, to be fixed to the strap without wrapping the leather round the bar, or sewing on an overlay piece, which would have limited the space for the strap point to enter? A sewing of fine copper wire through the strap and round the bar A made a secure job of it, and only took from the space the thickness of the copper wire.

All went together admirably, looked handsome, and realised the inventor's most sanguine hopes, till the hame-chain had to be unbuckled from the collar for putting away the hames and traces; then it was found difficult to get the strap point out of the bars of the buckle, as it was sunk below the buckle-frame, and could only be raised by the point of a knife, or a nail or hook.

The strap must be kept up in the frame high enough to allow the fingers to draw out the point easily. A middle bar is used in many buckles, and the tongue fixed on that bar, but in this instance it would not answer, so the device of a middle bar to uphold the strap point, with a gap in the middle to allow the tongue to lie down in the frame without taking the strap with it, was the plan devised. This is shown by D, D; and in Fig. 4 the buckle tongue is seen below the strap, and the strap above the frame at D, and answers well.

## DESIGN FOR A VILLAGE SCHOOL TO ACCOMMODATE 180 CHILDREN.

BY J. HALL.

*Introduction.*—The school is intended for a large village; it comprises one large school-room and one class-room for the senior boys and girls, infants' school-room, with a gallery, master's room, cloak-rooms, and two sets of latrines (one to each sex), and boys' and girls' playground.

The school and class-room would be fitted up with dual desks on raised platforms, a dado of salt-glazed bricks four feet high, with a moulded capping in same materials, to run round all the rooms, etc.

The master's room, class-room, and infants' school-room would be fitted with cupboards for books, etc.

The cloak-rooms to be fitted up with post and rail divisions, and hat and coat hooks. The lavatory basins to be 13 in. diameter, and the sinks 2 ft. 6 in. by 1 ft. for washing slates.

The heating of the rooms, except master's room, would be by stoves. The master's room would have an open fire-grate.

### SPECIFICATION OF WORKS (BRICKLAYER, ETC.).

*Bricks for Facing.*—The bricks for external facing to be the best hard, well-burnt, pressed red-facing bricks, laid in English bond; no bats to be used, flushed up each course, and to be neatly weather-joint pointed.

*Common Bricks.*—The bricks for internal facing to be the best hard, well-burnt common bricks from an approved yard, and to be finished with a rough surface to afford key for plaster.

*Glazed Bricks.*—The glazed bricks to be the best dipped salt-glazed bricks of approved brown tint, and to be set in fine mortar and pointed with Parian cement, and to have a cut joint.

*Ditto for Urinals.*—The glazed bricks for urinals to be best "seconds," as last.

*Mortar.*—The mortar to be composed of well-burnt stone lime and clean, sharp (river or pit) sand: proportions—three of sand to one of lime, to be well mixed and kept clean.

*Concrete.*—The concrete to be composed of an aggregate of five parts clean, broken bricks or stone, broken to pass through a 2 in. ring, and one part clean, sharp sand or fine gravel, and one part of ground lias lime from an approved maker, to be mixed by measure.

The floors of cloak-rooms to have a layer of broken brick or stone 6 in. thick, well rammed, and to have a layer of 2 in. thick of cement and fine gravel, two of gravel to one of cement; to be finished smooth with a coating 1 in. thick of fine crushed granite and cement, one coat to follow the other without allowing time to dry.

*Drains.*—The drains to be formed of best earthenware socketed drain pipe, jointed in cement, and to be properly disconnected with small chambers, with stone covers and grates in same.

*Gauged Arches.*—The arches of windows, doors, etc., to be formed of best red pressed wire-cut bricks, formed and set in cement on proper centering.

*Arch Bars.*—All fireplaces to have Gibbs' patent wrought-iron lintels, $2\frac{1}{2}$ in. by $\frac{3}{8}$ in., built 9 in. into the wall at each end.

*Ventilation.*—Fix Boyle's wall panel ventilators in all main rooms.

*Flues.*—All flues to be 14 in. by 9 in., and to be properly pargeted with cow-dung and hair mortar, a blank flue to be carried up each chimney-stack for ventilation.

Finish flues with a 1 ft. high strong fire-clay chimney-pot set in cement.

*Latrines.*—All the latrines to be fitted with automatic flushing closets.

*Stonework.*—All stone dressings to be of best quality, free from all defects, to be laid on its natural or quarry bed, and from an approved quarry.

Steps to be of Pateley Bridge or Bradford stone, sawn on top and edge and slightly chamfered.

Hearths to be of Bradford stone, sawn on one side and rubbed fine, laid solid on bed of mortar.

All stone to be worked in the best manner in every respect.

Sills to be checked, weathered, and throated.

TILER.—The roofs to be laid with best Broseley tiles to a 3 in. lap on 1 in. by $\frac{3}{4}$ in. sawn redwood battens, and each tile to be bedded in hair mortar, and nailed with two copper nails $1\frac{1}{2}$ in. long.

*Ridge.*—To be of approved pattern bedded in mortar, and to match tiles in colour. All valleys to have purpose-made tiles to pitch of roof. All tiles to be laid double at eaves. Do all cutting, etc., required.

PLASTERER.—Plastering to be three-coat work. First coat of two of sand and one lime, with 5 lb. of cow-hair to one cubic yard of stuff; second coat to be three of sand and one lime, and to be finished with a coat of fine putty, trowelled smooth and left perfect.

*Ceilings.*—Laths to be "lath and a half" of riven Baltic fir, and to break joints every four feet; to be nailed with wire nails to ceiling joists; to have coat of hair and lime as before to walls, and floated smooth and skimmed with fine putty, which has been made at least one month.

*Distemper.*—All walls to have two coats, and finished to approved tint.

CARPENTER AND JOINER.—Best Dantzic Riga or Memel fir to be used for carpenters' work of an approved brand, to be full-grown and well-seasoned, free from sap, shakes, large, loose, or dead knots, and all defects.

The joiners' work to be constructed of best Quebec yellow pine.

*Lintels.*—Put lintels to all openings with 9 in. wall hold at each end and as many inches in thickness as feet in bearing.

*Roofs to be framed as follows:*—11 in. by 6 in. principal rafters, 10 in. by 6 in. tie beam, 9 in. by 3 in. purlins, $4\frac{1}{2}$ in. by 3 in. spars, all framed in the most approved manner, with wrought-iron straps, bolts, etc.

*Spars.*—To be $4\frac{1}{2}$ in. by 3 in., and not to exceed 12 in. apart.

*Wall Plates.*—To be $4\frac{1}{2}$ in. by 3 in., and lapped and spiked at joints.

*Platforms for Dual Desks.*—To be formed of 11 in. by 2 in. joists (stepped), notched and spiked to plates.

*Roof Boarding.*—All the roofs to be covered with 1 in. thick boarding laid diagonally with shot edges and spiked to spars.

Fix stout feather-edge tilting fillet to eaves.

*Gallery Floors.*—Lay the floors of gallery with $1\frac{1}{2}$ in. thick tongued and grooved flooring, laid very close and cramped, puttied and dressed off, and with rounded nosing and $1\frac{1}{2}$ in. tongued risers.

*Seat Backs to Infants' Gallery.*—The seat backs to be formed of $1\frac{1}{2}$ in. stuff with rounded edge, held down to seat with angle irons, and to be grooved and tongued to seat.

*Wood Floors.*—9 in. by 3 in. by 2 in. tongued and grooved best St. Petersburg redwood or pitch pine blocks, set herring-bone pattern in approved asphalte composition.

*Doors.*—The internal doors to be 2 in. thick framed and panelled doors, and to be fixed with three 4 in. butt hinges to 2 in. thick rebated casings; fix a lock and furniture on each door, and put 4 in. moulded architraves round both sides.

*Doors to Latrines.*—To be 1 in. ledged and braced batten doors, each door to have two strong wrought-iron cross garnets to $4\frac{1}{2}$ in. by 3 in. beaded and rebated frames. Fix on each door a good barrel bolt and strong wrought-iron thumb latch.

*Front Doors.*—The front doors to be $2\frac{1}{2}$ in. thick, panelled and stuck moulded, fixed to $4\frac{1}{2}$ in. by 3 in. rebated frames, upper panel prepared for glass, and each to have good barrel bolts and lock and furniture.

*Windows.*—Fix up the windows with 2 in. double hung sashes with 1 in. moulded bars,

and in stout deal-cased frames, with 3 in. sunk and weathered English oak sills, to be fitted with brass axle pulleys, woven twine lines, metal weights, and approved strong brass sash fastener.

The windows above the transoms of large window and cloak-rooms, etc., to be fitted with pivot-hung sashes on stout pins, and fitted with iron stays.

Line all windows, etc., with 1 in. lining and window boards and 4 in. moulded architraves.

*Book Cupboards.*—The cupboards to be framed of 1½ in. stuff, panelled and stuck moulded fronts, with 4 in. plinths; doors to be hung with 3 in. butt hinges, and fitted with ¾ in. shelves.

All work to be of best quality and left perfect.

PLUMBER.—The eaves gutter to be formed of 5 in. half-round iron gutter, with ½ in. thick wrought-iron straps, fixed to spars. All lead to be best Newcastle milled sheet lead.

*Flashings.*—All flashings to be of 5 lb. lead, to be tucked and plugged into brick joints, not less than 1½ in., and pointed in oil mastic, and to be 6 in. under tiles with a small concealed gutter.

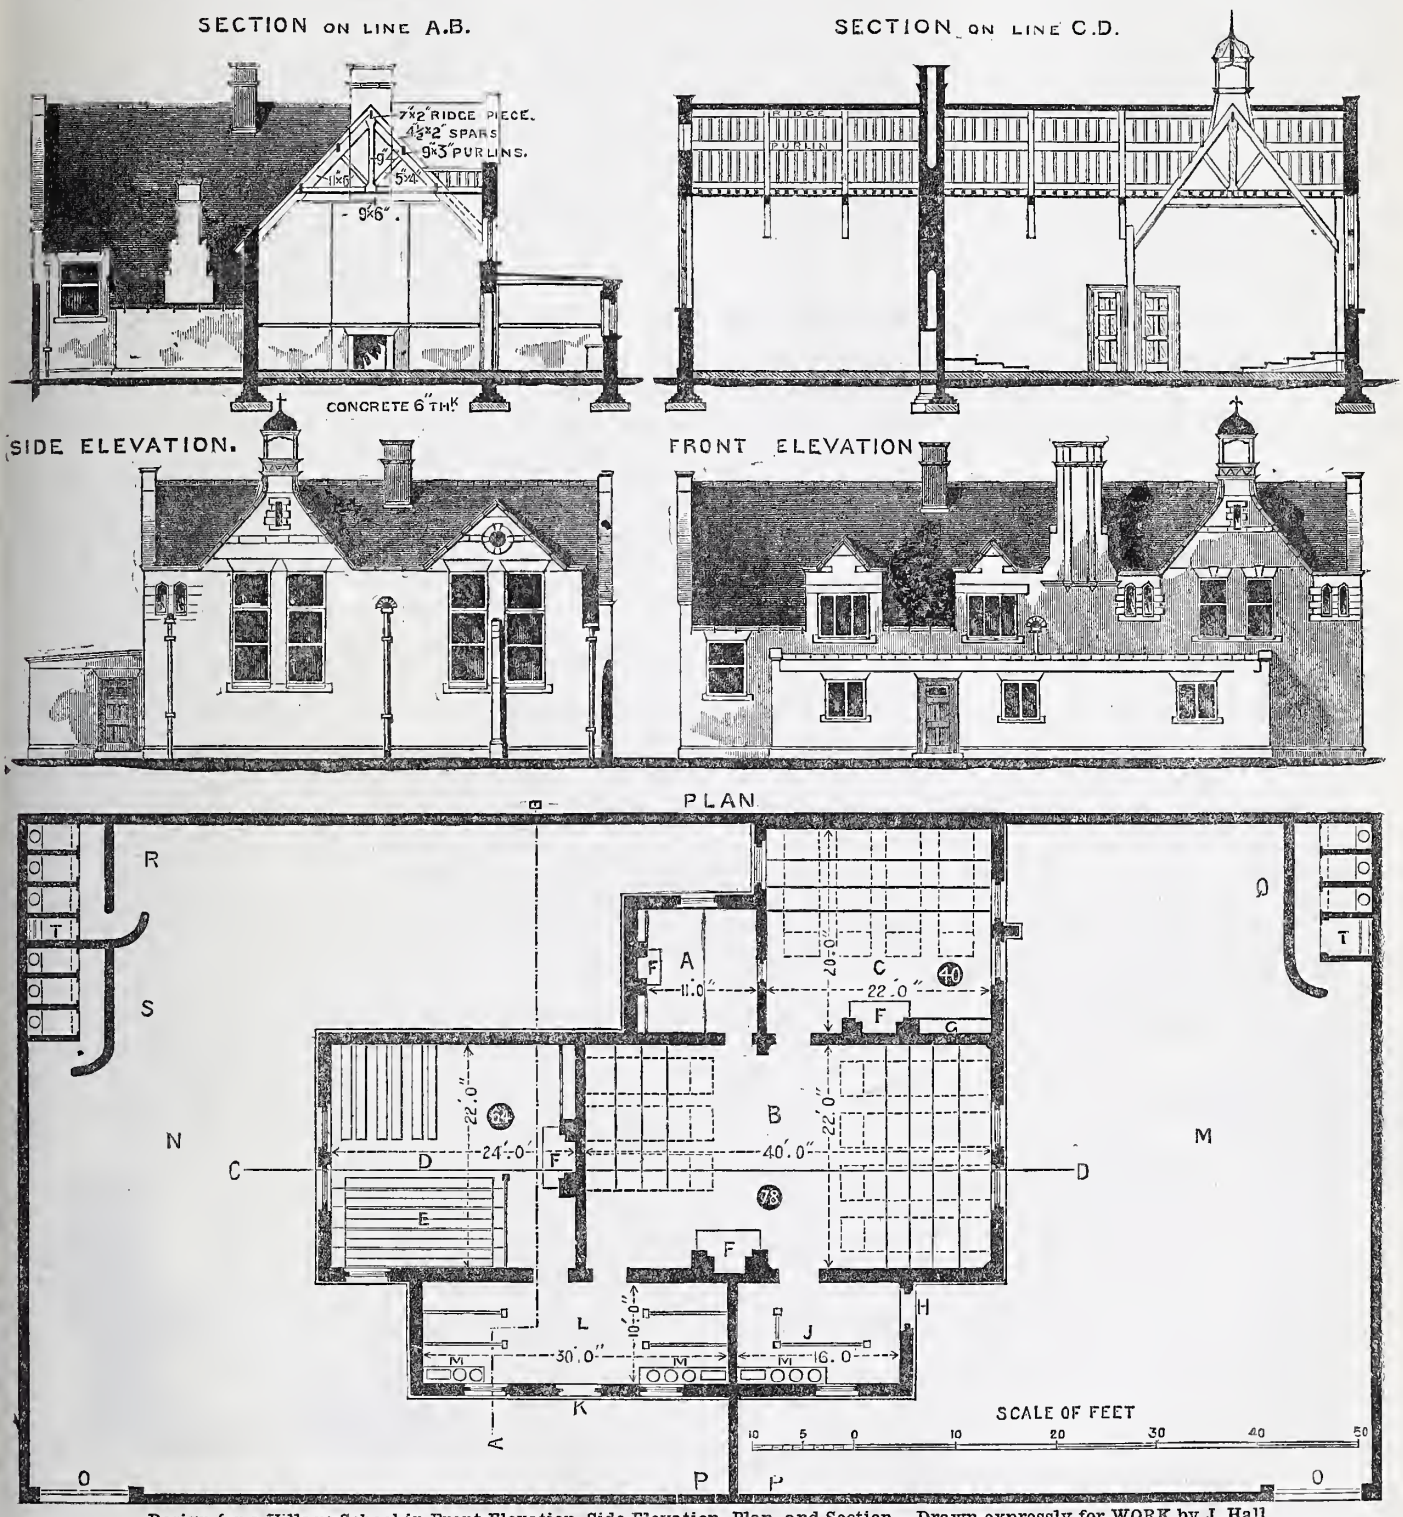
*Cloak-room Roofs.*—The cloak-room roofs to be covered with 7 lb. lead, neatly dressed over rolls and close copper nailed.

*Latrine Cisterns.*—The latrine ranges to have each a fifty-gallon flushing cistern, with proper connections.

*Turret Roof.*—To be covered with 7 lb. lead, and neatly dressed over rolls, and close copper nailed over edge of moulding.

PAINTER.—All materials to be of best quality, and painting to be finished to approved tints.

All white lead to be of the best quality of old white lead, and properly mixed with boiled raw linseed oil and turps, with colours ground in.



Design for a Village School in Front Elevation, Side Elevation, Plan, and Section. Drawn expressly for WORK by J. Hall.

*Wood and Ironwork.*—All wood and ironwork to be painted four coats good oil colours.

The sashes to be painted cream white, and doors, window-frames, etc., sage green.

All ironwork to be painted dead black.

The whole of the work to be carried out to the true intent and meaning of these plans and specifications, as may be reasonably inferred therefrom, and to be carried out in every respect in the most workmanlike manner, all omissions to the contrary notwithstanding.

The recent introduction of Free Education, and the probability of the establishment of village schools in localities where at present none, or mere apologies for them, are to be found, have induced the proprietors of Work to place at the disposal of any who may be disposed to avail themselves of them the Design and Specification above given. The proprietors have much pleasure in calling the attention of School Managers and Teachers to these helps to School Building, which are placed at their disposal for the mere cost of the present number of Work.—Ed.

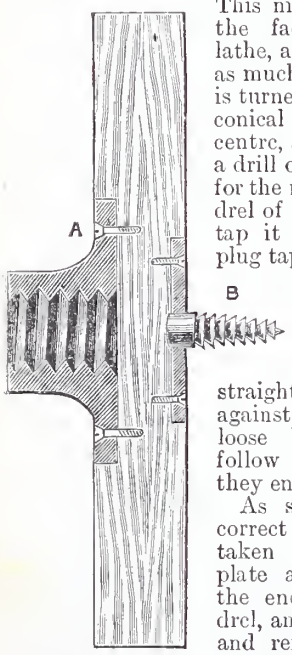
## A CHEAP LATHE CHUCK.

BY T. R. BLACKETT.

The accompanying drawing represents a section of a flange chuck with taper screw, the cost of which, if purchased, would be at least 5s. I made one a short time ago similar to the sketch, which cost about 2s.

The drawing is half full size, but the size may be varied to suit any lathe.

A brass casting, A, must be procured. This must be fixed on the face-plate of the lathe, and the back, or as much of it as can be, is turned true. Turn a conical hole in the centre, and drill it with a drill of a suitable size for the nose of the mandrel of the lathe; then tap it with taper and plug taps till it is a fit for the screw on the end of the mandrel. In order to keep the taps straight, fix their ends against the point of the loose headstock, and follow up the taps as they enter the chuck.



Section of Cheap Lathe Chuck.

As soon as it is a correct fit, it may be taken from the face-plate and screwed on the end of the mandrel, and the face, edge, and remainder of the back turned true; also drill four holes in the flange for counter-sunk-headed screws.

A piece of dry mahogany, 6 in. diameter and 1 in. thick, must be fixed on the face-plate and faced up, and a recess formed in the centre, which must be an exact fit for the brass casting already turned. The casting must be fixed to the mahogany by four screws, as shown at A. It is then fixed on the screw of the lathe mandrel, and the face and edge of the wood turned true.

A steel taper screw, about 1 in. long and ⅜ in. diameter, must be procured and fixed in a circular plate of brass 2 in. diameter, and which has been turned true; four countersunk holes for screws are drilled in the brass plate. The screw I used cost me 1s. complete, fixed in the plate.

A recess is turned in the centre of the wooden disc already prepared, into which the plate and screw are fixed by screws, as shown at B; the plate must be carefully fitted in, so that the screw runs perfectly true, before the screws are put in. This chuck will be found very useful for turning flat discs and short pieces of wood, which do not require the support of the loose headstock. There is also no fear of damaging the point of the tools in cutting out a ring, as when the flange is of metal.

## OUR GUIDE TO GOOD THINGS.

*** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of Work for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of Work without charge, the notices given partake in no way of the nature of advertisements.*

### 71.—Niedling's "Romanesque and Gothic Church Decoration."

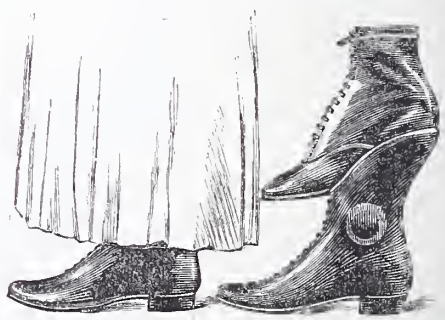
This publication is one of the finest samples of modern chromo-lithography that I have had the pleasure of inspecting. When the late Owen Jones—away back among "the sixties"—in one of his Marlborough House lectures on decoration, spoke of the glorious colourings of Gothic ecclesiastical decoration, "in which each and every moulding has its applied colour," he must have had in his mind some of the ancient works which A. Niedling has here re-drawn and coloured with so much skill and art for the benefit of our own times. The six plates contained in the first part show some clever drawing and handling of the figure, besides a wealth of purely conventional ornament of an ecclesiastial character, for bosses, ashlar work, side aisles, groined roof, and perpendicular and horizontal borders, with sacred emblems introduced therein. For the better appreciation of the professional utility of this publication, I am pleased to give a place to the opinion of a skilled and experienced contributor. He says:—"Niedling's 'Church Decoration' should be in the hands of every man who professes to design and execute Gothic decoration. The whole of the designs are very judiciously selected, and contain much that is entirely fresh in form and treatment. The colouring is very charming, and scholarly in every example; and coming, as the work does, at a period when the High Church revival of ecclesiastical art is beginning to make itself felt in all directions, I consider it a valuable acquisition to every architect and decorator who can appreciate the æsthetic and phonetic beauties of pure Gothic decoration." The price of this publication, consisting of twenty-four sheets, each 18 in. by 12 in., is 48s., or 12s. each four-part division. To those of the artistic cult amongst the friends of Work who are acquainted with the "Art Decorator," no further evidence of the monetary value of this production will be required. A specimen plate costs 2s.

### 72.—Zander's "Modern Decoration."

I have heard it stated, by one who was very competent to express an authoritative opinion on the subject, that the practice and art of house and church decoration is but in its infancy in this country. Judging by the number of costly books upon the subject which have recently been placed upon the market, there are apparently many publishers who have a like opinion and faith. The above-named work appeals chiefly to professional painters and decorators, and consists of thirty large designs, in chromo-lithography, for the decoration of ceilings, walls of dining- and drawing-rooms, boudoirs, studios, vestibules, staircases, etc. Although the entire work, in its original German edition, is now completed, the first part only of the English reprint is yet in the publisher's hands; the remaining parts will quickly follow. Each part-issue contains six sheets or sets, for wall and ceiling treatment, printed in the finest possible manner, and mounted upon grey-tinted cards. Although the decorative treatments are more characteristic of Continental decoration than of modern British work, they are full of suggestion and instruction to the decorator who strives to display some freshness and originality in his designs. To the practical master-decorator, especially of the provinces, the work would prove of considerable value, and a set of plates, suitably framed, would materially conduce to the artistic tone of his show-room. The work may be obtained complete, in a suitable portfolio, the thirty plates—size about 18 in. by 12 in.—for £3. The price of a single sample plate is 2s. post free; each part, containing six plates in colours and gilding, being published at 12s. I may further mention, as evidence of their artistic excellence, that sample plates may be seen at the German Exhibition.

### 73.—Improved Boot for Shortened Leg.

"One-half the world is occupied in thinking what the other half is thinking of it," is an aphorism which is constantly manifest, in the affairs of life, in appearances that one-half present to the other in general civilised society; and, perhaps, in no aspect more critically than personal appearances. "The knightly man, though obscure," was the aspiration of a princess. The gentleman, the athlete, is the beau ideal of many who are not princesses. If men or women are afflicted by deformity, they wish to conceal it from the world. It is a laudable feeling, and if art or science, tact or talent, can honestly spare the sensitive feelings of the afflicted, it serves humanity sometimes where nature fails. The deformity to feet of men and women is an affliction which is keenly felt by the afflicted when others regard them pityingly. If the deformity is unseen by others, a sense of relief is felt, and feelings spared. Many feet now encased in hideous frames of cork, iron, or leather, of awkward contrivance for pedomotion, are practically perfect feet, the human ill being either in the knee or hip, which has contracted a leg at one of those parts, and to make the legs even in length the club-boot is put on a perfectly healthy normal foot. This has been done almost up to the present time, till a Mr. Tyrrell was called upon to make a club-boot for a perfect foot of a distinguished man. He refused to do



so. "I will make you a pair of boots alike for even tread on the ground, and a boot to fit your foot at its present height from the ground, so that when you stand there will be no difference of boots you rest on, and your trousers will hide the upper boot on your shorter leg." This was common sense, and delighted the afflicted one, and soon led to orders from all parts for double-storey boots for those with hip and knee contractions. Of course, the lady's skirt effectively conceals the upper boot, as do the trousers of a gentleman. The illustration speaks for itself

### I.—Letters from Correspondents.

**Rate of Circular Saws.**—CHOPSTICK writes, in reply to A. R. (*Scorrier Saw Mills*) (see No. 128, p. 379):—"I beg to say that I am still of the opinion that it would be extremely difficult to find a joiner who would be willing to saw 3 in. deal with a rip saw. A. R. seems to think that I am a master, but I am only a journeyman, and I should certainly refuse to do so; and if I were a master, I should refuse to allow my men to do so if they would, as the game would decidedly not be worth the candle. I suppose from his letter that A. R. is the proprietor of the Scorrier Saw Mills. If so, of course it is to his interest to sneer at home-made machinery; but I have made and used a saw-bench which not only cut any thickness up to 3 in., but did tenoning and grooving on it, and I intend sending a description of the machine to WORK, and, if it is accepted, others will have the chance of proving my words correct. It is scarcely possible to find a joiners' shop without a mortising machine, but I think the circular saw is of far more benefit. A. R. says that he sharpened a joiners' rip-saw, and cut 3 in. pine for two days, and it went grand. I never yet saw one which would cut for two days without sharpening, and I must say that A. R.'s statements will hardly hold water. However, he may think what he likes. I have had experience both ways, which I do not think he has, and I will guarantee that I can saw out as much 3 in. deal in one day, with a labourer to turn, as six joiners can with the rip saw in the same time, and both the labourer and myself work comfortably."

**Rate of Circular Saws.**—A. R. (*Scorrier*) writes:—"I was not only surprised, but amused, when I read CHOPSTICK'S reply to CONSTANT READER on p. 398, No. 129. In No. 120, p. 251, CHOPSTICK wrote strongly condemning my argument in No. 116, p. 187, *re* 'Rate of Circular Saws,' and tried to convince the readers of WORK that it was an easy matter to cut 3 in. deep with a circular saw driven by hand. In his reply to CONSTANT READER (see p. 398), he said you must not expect to cut 3 in. stuff without some hard work, and it is best to have two men to turn the wheel. Now, I ask, what notice is there to be taken of a man that will support a thing in one number and in another condemn the same? It is like a child getting a rod with which his own back is to be beaten. I hope, when CHOPSTICK gives his promised information to CONSTANT READER, that it will not be misleading: that he will not try to open one's eyes in one number, and blind them in another. I understand that the object of WORK is to enlighten its readers; and those that write letters and replies should write with that intention, and not for the mere sake of argument."

**Cost of Patents.**—The following is a cutting from the "Inventors' Column" of the Melbourne *Daily Telegraph* of August 8th, by Mr. G. G. Turri, F.S.C.I. I make no apology for reproducing it, as I am sure it will be of interest to many readers of WORK:—

"There are so few books on patent law adapted to the taste of the average inventor, that the one now before me is very welcome. It is highly essential the inventor should know certain facts before he takes out patents, otherwise loss ensues. One important point is, 'What do patents cost?' I find the following table in a work entitled 'Patents for Inventions, and How to Procure Them,' by G. G. M. Hardingham, a well-known consulting engineer and patent agent of London:

| Country. | Patent Office Charges and Terms. |
|---|---|
| Great Britain ... ... ... ... | £154 in 14 years |
| Germany ... ... ... ... ... | £226 in 15 years |
| France and Colonies ... ... | £60 in 15 years |
| India ... ... ... ... ... ... | £52 in 14 years |
| United States ... ... ... ... | £7 in 17 years |
| Canada ... ... ... ... ... | £12 in 15 years. |

"To this I add the figures for Australasia:—

| | | |
|---|---|---|
| Victoria ... ... ... ... ... | £8 | in 14 years |
| New South Wales ... ... | £5 | ,, |
| Queensland ... ... ... ... | £20 | ,, |
| South Australia ... ... ... | £9 | ,, |
| Tasmania ... ... ... ... ... | £45½ | ,, |
| New Zealand ... ... ... ... | £17½ | ,, |
| West Australia (L.R.) ... | £15 | ,, |
| Total for Australasia ... ... | £120. | |

"These do not include the varying charges of patent agents, and further it will be understood that in most cases the fees are payable in small instalments at intervals, so that any patentee, finding the invention unremunerative, can let the patent lapse, and so avoid paying the great bulk of the above charges. Thus in England only £4 is payable during the first four years. But taking the above table and noting the average annual cost, and bearing in mind the present population of each country, I get the following startling results:—

| | | | |
|---|---|---|---|
| In United States | The expenditure of 1d. in Patent Office fees gives a monopoly right for a year over | 670,000 | persons |
| France ... ... | | 73,000 | ,, |
| Canada ... ... | | 26,000 | ,, |
| Great Britain | | 14,000 | ,, |
| Germany ... | | 12,000 | ,, |
| Australasia ... | | 2,000 | ,, |

"This table is of some value. When federation takes place the Australasian colonies will cease to occupy the miserable position above shown, and will jump to the level of Canada. At present, New South Wales shows 13,000 and Victoria 8,000 to the 1d.; but the other colonies rank terribly low. Let us hope that the rights conceded to patentees in Australia will soon (like the kiss which the lady returned to Rodolph) be *revu corrigé et considérablement augmenté*.

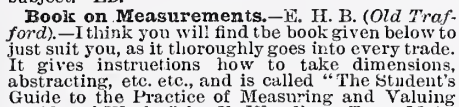
**Carpentry Classes.**—R. A. P. writes:—"About two years ago I saw a paragraph in the columns of 'Shop,' recommending for 'Tuition in Carpentry,' Mr. S. Robertson, 14, Augustus Road, Hammersmith, who holds evening classes at that address. I at once went to him and joined his classes, finding them of great benefit, so much so that I joined them again the following winter (1890-91), and I fully intend to do so again this winter. They will commence about the end of this month (September) or beginning of next (October), and I should advise your numerous readers—some of whom, like myself, may live in the vicinity, and to whom it might be a convenience and a great benefit—to take advantage of the opportunity. I cannot speak too highly of his merit as a teacher."

### II.—Questions Answered by Editor and Staff.

**Ash-pan Making.**—J. W. (*York*). **Netting.**—J. H. (*West Bromwich*). **Lamp for Lantern.**—PEDAGOGUE. **Door.**—COWL.—*** The replies to queries on the above subjects must necessarily be given at considerable length to be of any practical utility and value to those who are seeking information on them. The answers are far too long to be included in "Shop," and will therefore appear as short articles in the body of the magazine. "Shop," it should be remembered, is intended to meet the wants of those who are in need of information on any single point connected with any particular subject, and not to deal with subjects themselves from the commencing Alpha to the ending Omega. For the future, contributors must bear in mind that those questions which involve over-long replies cannot be entertained, or must wait to be dealt with by a special paper on the subject.—ED.

**Book on Measurements.**—E. H. B. (*Old Trafford*).—I think you will find the book given below to just suit you, as it thoroughly goes into every trade. It gives instructions how to take dimensions, abstracting, etc. etc., and is called "The Student's Guide to the Practice of Measuring and Valuing Artificers' Works," by E. Wyndham Tarn, M.A., price 10s. 6d. Published by Crosby Lockwood and Co., London.—E. D.

**Electric Light.**—N. M. (*Dundee*).—Your 20 volt 10 c.-p. lamp will require a battery of ten or eleven such cells as you propose to light it efficiently, and the cells will need re-charging every three or four hours. If the zinc plates touch the bottoms of the cells, you may have a layer of mercury in each cell to keep the zincs amalgamated, but the carbon plates must not touch the layer of mercury. If the zincs do not touch the bottoms of the cells, the mercury will be useless. The carbons must have lead heads, but it is not necessary to cast the carbons in a ring of lead. You may employ a set of carbon plates, each furnished with a separate head of lead, as in the carbon plates used in Leclanché cells, or those shown in your sketch. A wood support of teak or of mahogany, well soaked in paraffin wax (as suggested), may be employed to support the plates. Strips of brass or of copper may be fastened to the upper surface of this support, to form connections for the carbon plates. These should be arranged in



as shown in your sketch. In your arrangement the two outside carbons would be almost useless, as their surfaces would be out of range of action. The large round cells, each with a central plate of zinc, 6½ in. × 4 in. × ⅜ in., flanked by carbons 7 in. × 2 in. × 1/16 in., as shown above, will be preferable to cells of a smaller size. See that the tang of the zinc plate is well insulated from the connecting strip of brass on the wood support. This strip on one cell must be connected to the zinc of the next cell, and so on through the series. Charge the cells with bichromate of potash or chromic acid, 3 oz. in each pint of water, acidulated with 3 fluid oz. of sulphuric acid (common oil of vitriol). Use No. 16 B.W.G. copper wire to connect the cells in forming the battery, and No. 18 B.W.G. wire to connect the battery with the lamp. I shall have much pleasure in giving you further advice if you require it; but please understand that we do not answer letters by post. Replies must be made in "Shop," and will appear in due course, as space can be found for them.—G. E. B.

**Simplex Dynamo.**—W. D. (*Belfast*).—Mr. S. Bottone, Electrical Engineer, Wallington, Surrey, can supply you with castings and other materials for making a dynamo of the Simplex pattern. A set of castings, with east annealed ring armature 3⅜ in. in diameter, and wrought-iron core 4 in. in length by 2 in. in diameter, will cost 12s. 6d.; or with thin iron plates 3 in. in diameter for a laminated armature, at 24s. the set. He does not recommend the H girder armatures for these machines, as they get too hot; but the price would be the same as that of the ring armature. The wire required will be 1 lb. of No. 20 d.-c.-c. on the armature, and 5 lbs. of No. 20 d.-c.-c. copper wire on the field-magnet core. This machine will develop a current of 2 ampères at a pressure of 25 volts, or enough to supply 20 candle-power. I am glad you find WORK so useful. The captain of our ship decides on the cargo to be carried, and he alone can say when induction coils will be placed aboard.—G. E. B.

**Safety Fuse for Electric Light.**—R. C. J. (*Staffordshire*).—Your lamp may be protected from injury by an accidental rush of current by means of a safety fuse, a safety magnetic cut-out, or a suitable resistance placed in circuit with the lamp. Arrange a Cockburn fuse in circuit with the lamp, to melt at, say, twice the normal current taken by the lamp. This will be, for a 100 volt 16 c.-p. lamp, about 1 ampère. Now, No. 36 B.W.G. fusible tin wire will melt with a current of 1 ampère. Arrange, therefore, a short length of this wire as a loop in the lamp circuit with a small weight (such as a ring or a pellet of lead) depending from the loop. Should the current exceed in strength 1 ampère, the fuse will melt and the weight fall, thus cutting the lamp out of circuit. A fresh piece of wire must be put in after each such accident, and this may form the cause of an objection to a safety fuse of this kind. This being so, I should advise the use of a Cunnyngham's or other magnetic cut-out instead of a safety fuse. Magnetic cut-outs are merely electro-magnets placed in circuit with the lamp, together with a make and brake arrangement controlled by an iron armature placed within the influence of the electro-magnet. The armature can be set so as to cut out the lamp when more than 1 ampère is passing through the magnet coil. You can easily devise the necessary arrangements to do this. If this cut-out is used in conjunction with an adjustable resistance, you can alter this at will, and thus effectually guard the lamp. One of the best adjustable resistances for such a purpose is that of a carbon rod dipping into a metal cylinder filled with water. The cylinder and the rod-holder are connected in circuit with the lamp, and the rod is immersed more or less in the water until the desired resistance is secured. A metal pail will do instead of a cylinder. The carbon resistance may also take the form of two strips of carbon resting on a slate base and on each other; the resistance varying with the surface of carbon in contact. As arcs are liable to be formed between the two surfaces, this is not so good as the former form of carbon resistance. In conclusion, I must point out that you cannot (as you suppose) reduce the voltage of the current by means of a resistance. It is the strength of the current as expressed in ampères by an ammeter—not voltage, as shown on a voltmeter—that will be reduced. I am pleased to hear of your success in following instructions given in WORK.—G. E. B.

**Soldering Zinc to Brass.**—SOLDER.—Scrape the surfaces which are to be soldered quite clean and bright. Moisten the cleaned surface of the brass with a little ordinary soldering fluid (chloride of zinc or killed spirits), and tin it in the usual way by rubbing the hot soldering bolt on the prepared surface of the intended joint. Get the soldering bolt moderately hot, moisten the cleaned zinc surface with a little crude spirits of salts (muriatic acid), and press the zinc with the hot bolt on the tinned surface of brass. This will cause the two surfaces to adhere. The edges of the seam must now be moistened with spirits of salts, a bead of solder applied, and drawn along by the hot soldering bolt to make the joint neat and secure.—G. E. B.

**Nickel-plating Steel.**—C. V. (*Bath*).—The cause of your failure in attempts at nickel-plating steel is simply want of experience. No book contains definite instructions calculated to meet every difficulty likely to be experienced by amateurs. General laws can only be laid down in books, and these must be applied to by intending experimenters. As you have the "Electro-platers' Handbook," I will quote from it to show you that the general law applicable to your case is there given. On p. 171 you will find: "A successful result largely depends upon the regulation of the current. If this is too intense, the nickel will be thrown on in small hard grains, which will not present any surface capable of being polished; or the deposit will be ragged: that is, specked with tiny blisters, which will cause the metal to strip and leave a ragged appearance on the coat. Both of these defects are due to excessive evolution of hydrogen at the cathode. When small steel articles are placed in the nickeling solution by themselves, this tendency to blister and cast off the coat of nickel is sometimes very troublesome. This fault may be remedied by placing each steel article between two of brass or some other metal, and thus divert part of the current on each side by easier paths." The strength of current must

be regulated to the strength of your solution. When both are balanced, the deposit will go on all right. Alter the battery, reduce or increase the anode surface, or place this nearer to or farther from the article, until the proper conditions have been found by experience. Your arrangement of vat, rods, battery, etc., are all right. The solution might be denser with advantage. I should advise you to get an experience in depositing nickel on brass and on wrought iron before you attempt depositing on steel. I think you will concede that you are serving an apprenticeship to this trade, and should, therefore, try the easier jobs before attempting such difficult ones as those stated in your letter. Brass and iron may be plated together in one solution after you have mastered their peculiarities by experience.—G. E. B.

**Shocking Coil.**—T. W. (*Bolton*).—We endeavour to oblige all our readers with replies to their questions, but cannot see our way clear to give you instructions how to make a shocking coil to send a shock through thirty or forty persons at the same time. You have not, evidently, given this question serious consideration in all its bearings, and specially in those relating to the possible consequences following a shock from such a coil. A shock from such a coil might cause death to one or two persons in the ring, should they be suffering from heart disease, or might cause permanent injury to the health of others. Such shocks can do no good; and the practical jokes played with coils are of such a questionable character as to merit severe denunciation.—G. E. B.

**Cases for Binding Vol. I. of WORK** are on sale by Messrs. Cassell & Co., the publishers of WORK, at 1s. 6d. each. The cause of delay rests entirely with the newsagent.—G. E. B.

**Brass Savings Bank.**—D. S. (*Glasgow*).—You leave the design to me, but you ought to have said whether you desired one of a geometrical pattern, villa or house, figures, or some fancy object. I give this one, hoping you will find it suggestive. It will be advantageous to have five separate compartments, as then they could be allotted for the use of five different members of a family, or could be disposed for the saving of copper, silver, and gold

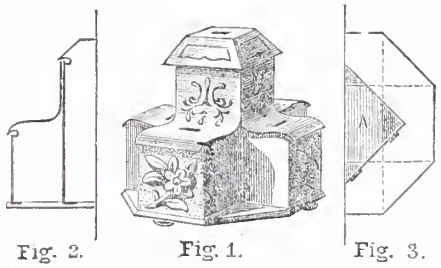


Fig. 2. Fig. 1. Fig. 3.

**Fig. 1.—Perspective Sketch of Bank. Fig. 2.—Cross Section (half). Fig. 3.—Plan (half).**

coins individually in lots, distinct from each other. I cannot enter into details of constructing this box, beyond saying that I should put it together as in section, Fig. 2; but I believe you will find many useful hints in Mr. Alexander's papers on "Sheet Metal Work," given from time to time. A small square door in the bottom, as in plan, Fig. 3, would, when opened, expose the interiors of all the five compartments, and facilitate easy extraction of the coins within.—J. S.

**Wooden Mole-traps.**—J. J. (*Cumberland*).—I have made inquiries for a firm who supplies the above wholesale, but am sorry to tell you that I have not succeeded in finding one. Perhaps some of our readers may know, and will oblige us with the information. They have wire springs attached to them, says our correspondent.—J. S.

**Improved Watch Key.**—D. B. D. (*Glasgow*).—I have examined the sketch sent us, and think it novel, but fail to see that it would pay for the trouble and expense of patenting and introducing to the public, especially as the use of keyless watches is extending, and they are found so much more convenient. It may be urged, in reply, that there are still a great number of key-winding watches in existence, and that, therefore, there must be a good field for the improved key. This is a question more fitted for our correspondent to decide, and must be entirely decided by him.—C. E.

**Hydrostatic Clock.**—R. F. (*Newcastle*).—I am afraid I do not quite make out what you mean by a "hydrostatic" clock. I do not know of anything by that name; and on turning to the dictionary, I find "Hydrostatics—science which treats of properties and pressure of fluids at rest." And under the circumstances, I do not know how to assist you. No doubt it may be ignorance on my part, for which I apologise. But would the clock illustrated and explained in WORK, No. 125, under the heading "Sand Clock?" If so, I shall be glad to give you any further assistance in my power. It would be easy to make, and would simply require the bottom vessel emptied, say, once a day.—A. B. C.

**The Horizontal Position of Drawers.**—D. B. D. (*Glasgow*).—A person making an improvement for any purpose which is a novelty, is useful, clearly and properly described, with the claims sufficiently and properly drawn, may obtain a valid patent; but he must distinctly point out in what the novelty consists, and not claim as new anything that has been published or known before. If the inventor our correspondent alludes to has done something in a better way than any known up to that time, he can, of course, go for a patent; but then, it must be so drawn as to be in conformity with the legal requirements in a patent as to enable the law to support; otherwise, such a patent is of no good, and it is waste of time and money to obtain such; and this, it is needless to say, cannot be done unaided by any of the ordinary run of inventors.—C. E.

**Provisional Protection.**—A CONSTANT READER.—Any inventor who has obtained the grant of a provisional protection for a given thing cannot be considered safe in making it known whilst there is an earlier provisional protection for the same kind of thing open. If the writer is in the hands of a competent agent, or engineer of experience in patent matters, he would be able to carry him through, and advise him as to his best course; but if he—as too many are so fond of doing—has prepared and put in his own documents, he must fight his battle himself, the results of which he will find neither economical, or beneficial, or encouraging. An invention, if good for anything, and intended to be made a property, requires the aid and assistance of one properly qualified to do the required work in a suitable manner; and though a patent is nearly sure to be granted in response to the application, it may be no more a "property" after than before. Inventors and the extensive class who want skilled work and experience to be obtained for nothing will soon find out their folly and ignorance.—C. E.

**Perpetual Motion.**—F. T. (*Dundee*).—By the above term is usually understood an arrangement and combination of parts of inanimate matter in such a way that, when put together, they shall contain within themselves the power of motion, and keep in motion until the wear and tear of the parts prevent them from continuing to do so. Such an idea, practically, is an utter absurdity; and were it practicable, man would then be endued with the power of *creation*, which is one of the greatest attributes of the Almighty. That some very useful and ingenious movements and combinations have been obtained by the search is very true; but in order that our correspondent may thoroughly understand the subject, he should read "Perpetuum Mobile," by our old friend the late Henry Direks, C.E., which contains much valuable information on the subject.—C. E.

**Sizes of Tapping Drills.**—AXLE.—The sizes given in the list below are those I use, and are approximately correct for both cast and wrought iron; though, of course, to be exact the drill should be rather larger for wrought iron than cast, especially in the larger sizes.

| *Diameter of Screw.* | *Diameter at Bottom of Thread.* | *Approximate Size of Tapping Drill.* |
|---|---|---|
| $\frac{1}{4}$ | ·1859 | $\frac{3}{16}$ bare |
| $\frac{5}{32}$ | ·2413 | $\frac{1}{4}$ |
| $\frac{3}{16}$ | ·2949 | $\frac{5}{16}$ full |
| $\frac{7}{32}$ | ·346 | $\frac{11}{32}$ |
| $\frac{1}{4}$ | ·3932 | $\frac{25}{64}$ ($\frac{1}{8}$ + $\frac{1}{64}$) |
| $\frac{9}{32}$ | ·4557 | $\frac{29}{64}$ ($\frac{7}{16}$ + $\frac{1}{64}$) |
| $\frac{5}{16}$ | ·5085 | $\frac{1}{2}$ |
| $\frac{11}{32}$ | ·571 | $\frac{9}{16}$ |
| $\frac{3}{8}$ | ·6219 | $\frac{5}{8}$ |
| $\frac{13}{32}$ | ·6844 | $\frac{11}{16}$ |
| $\frac{7}{16}$ | ·7327 | $\frac{3}{4}$ less $\frac{1}{64}$ |
| $\frac{15}{32}$ | ·7952 | $\frac{25}{32}$ |
| 1 | ·8399 | $\frac{13}{16}$ + $\frac{1}{64}$ |

**Circular Saw.**—A. T. (*No Address*).—You have worked out the speed of your saw spindle correctly; but I cannot say whether it is too fast, as, in speeding a circular saw, the diameter has to be taken into consideration, which you have not given. If the saw is not above 12 in. in. diameter, the speed is not too fast in cutting soft wood. But for cutting hard wood, the pulley should be about 1 in. larger, which would bring it to about the right speed. A. T. should write again, stating gauge and diameter of his saw, also number of teeth, and what the trouble is, and he may expect a definite reply.—A. R.

**Dulcimer.**—H. J. C. (*London*).—I am very pleased that you have been so successful with your F dulcimer. If you want to make an instrument "suitable to play at a social concert," I should advise you to make one of the D or concert size, the dimensions of which would be: Length, front, 2 ft. 10 in., back, 1 ft. 4 in., depth from front to back, 1 ft. 4 in. Such an instrument is suitable for any work, and stands in a convenient key, but, of course, you could make one to any size you like. If you make one, as you suggest, 3 ft. 2 in. at bottom, and with additional semitones in the bass, that would necessitate the provision of three more bridges on the bass side, and a depth from front to back of 1 ft. 7 in. (The treble is already chromatic.) The additional notes would entirely alter the scale of the instrument, and render it much more difficult to play, on account of the "dodgy" character of the beating which would be necessary. If you build one 3 ft. 2 in. at bottom with the ordinary scale, then the top should be 1 ft. 7 in., and the depth 1 ft. 6 in. To get a full volume of tone out of an instrument of this size, I should advise you to make it with five strings to each note, and to string it with Nos. 11, 10, and 9 brass and Nos. 8 and 9 steel wire. The same width of blocks would do as for an F, as there would be ample room for an additional row of pins on each. Your idea of increasing the sound by replacing the inner bridges with stays similar to those on the back of the sound-board of a piano would have the opposite effect, as these bridges act as sound-posts between back and belly as well as supporting the latter, which, without them, would pucker or swamp as soon as the pressure of the strings was brought to bear upon it. Your question regarding a portable harmonium shall have consideration. In conclusion, allow me to say that if all our correspondents were as explicit as you are they would earn the lasting gratitude of those whose duty it is to reply to them.—R. F.

**Patent Drawings.** — VERAX. — It is in the interests of patentees that the Patent Office requires the drawings to be clear, black, and well lettered—first, that the photographs taken therefrom for the published specifications may be clear and intelligible; and secondly, that when they come before the courts at a trial, the legal mind can readily follow and understand them. C. C. C. is very much in the habit of dogmatising on Patent matters, and putting himself forward as an authority on a subject of which he has shown and proved himself grossly ignorant—witness, for example, his telling persons who want to make a search to go to the British Museum to examine specifications! and then, when he was shown what nonsense he had been writing, endeavoured to put it off by saying it was needed if an inventor wished to "see the patents at length!"—whatever this may mean. It is pretentious amateurs and dabblers of this description who are misleading inventors, increasing the number of useless and invalid Patents, and causing Patent property to be lightly esteemed and ridiculed. The drawings filed by our correspondent can only be esteemed as rough "sketches," and not by any means as "drawings" in the mechanical sense of the term; and this would be quickly proved if ever they came into the Law Courts.—C. E.

**Patent.**—ONE OF YOUR CONSTANT READERS.—It is amusing to see the readiness with which persons entirely ignorant of a subject will set themselves up to guide and instruct others, and what useful and infallible authorities they consider themselves! Our correspondent informs us of one of these, who had "registered an idea" (!) at the cost of £1. Now, in the first place, an "idea" cannot be patented. The only thing that can be patented is a *new* manner, method, or mode of performing or producing *something;* and unless a manner, method, or mode is described, such Patent (if granted) would be invalid and useless. The object to be attained in trying to obtain a Patent is the creation of a property, and one which the law will support. Unless this is done, time and money will be wasted, and it is almost needless to add that this cannot be done by the ordinary inventor, though he may put in some papers himself, and get a so-called Patent granted in response. The first thing our correspondent should do is to ascertain if his invention is *novel*, has not been patented before, and that there are no provisional specifications of an earlier date in existence for the same subject. Now, the grant of a provisional protection assures the inventor that no *later* applicant can take precedence of him under the subject of the invention. This provisional protection lasts nine months from the date of application, and before the expiry of this term the complete specification, claims, and drawings must be filed, or the Patent is *lost*. If, however, it is found that what has to be done cannot be completed within that term, an extension of time of one, two, or three months may be applied for, for one of the three periods named, with the stamps for fees of two, four, or six pounds impressed upon the application; but *no further* extension of time will be granted. The cost of a patent will entirely depend upon the amount of work to be done in the search, drawings, specifications, etc.—in fact, unless this is known beforehand, no one can name a price which shall be fair to both parties. The Government fee of £1 on the application no more represents the cost of what has to be done than the penny stamp on a letter settles the value of its contents, or the stamp on a legal document covers the cost of preparing it. If a provisional protection is obtained for an invention under a certain subject, and there are one or more prior provisional protections in existence for the same subject, there is always the risk that, on showing the protected invention, it may be appropriated and embodied in one or other of them, in which case the inventor will be nowhere. A little consideration should satisfy any man of common sense that a person totally ignorant of a given subject is not, and cannot be, qualified to instruct others, or properly to perform what is required therein. If our correspondent has got a thing that is useful and new, let him place himself in the hands of one who knows what has to be done, and how to do it, and is thereby qualified to secure for him what he desires.—C. E.

**Contract.**—J. P. (*Manchester*).—I can hardly understand from your note the precise nature of your requirements. For instance: do you want to know how to take dimensions off drawings or on the ground? Or do you want a book of prices? The act of contracting really is merely the stating of a certain sum, for which you are prepared to do a specified amount of work. Write for the "Contractors' Compendium and Complete Catalogue," by John Edward Sears, published by the Compendium

Publishing Company, 16, New Bridge Street, E.C. It states that it is published for 5s., but I know for a fact that it is given free to the trade. You will, I think, find it very useful; for not only does it give a dictionary of manufacturers' specialties, with their illustrations and price, but it also gives a "price book," divided into four sections. Section I., schedule of all trades; Section II., schedule for a dwelling-house; Section III., schedule for a church; and Section IV., builders' measured bill.—E. D.

**Clock Case.**—G. W. (*Birmingham*).—The works, without cases, can be supplied by any dealer in clocks. There is no difficulty in getting them.—D. D.

**Removing Ink Stains.**—H. S. A. (*Wolverhampton*).—I do not know of the particular fluid to which you refer as being sold to remove ink stains; but you can easily make one yourself by dissolving some oxalic acid in water. In using this material be careful, as it is a deadly poison.—D. D.

**Whitworth Scholarships.**—ANGLO-CYMRO.—There are thirty scholarships, each tenable for one year, some of the value of £100, and the rest of £50 each. There are twelve scholarships, tenable for three years, of the value of £125 a year each, four being awarded each year. The limit of age is twenty-six years. The competition is in theoretical subjects; but the candidate is required to have been engaged in handicraft in the workshop of a mechanical engineer for at least three years. The idea is to give as nearly as possible an equal chance to the highly qualified student and to the skilled workman. But for complete particulars I must refer you to the Secretary of the Science and Art Department, South Kensington, S.W., who, on receipt of 3d. in stamps, will send you a full prospectus of the Whitworth Scholarships.—J.

**Poker Work.**—POKER.—To describe poker work in all its details would require a treatise; but the following hints may be of service:—Well-seasoned, hard, white woods are the best to work upon, as sycamore, box, holly, American white wood, etc. The design to be burnt may be drawn directly upon the wood, or it may be drawn upon tracing paper and transferred to the wood with old carbon paper, old paper being used in preference to new, which marks the wood. The wood must have a smooth surface, such as is imparted by rubbing down the planed surface with fine glass-paper. The design may be burnt out, or the background may be burnt, leaving the design in relief. For etching the lines a special piece of apparatus, costing about £1, is used. You can get it of W. Barnard, 119, Edgware Road, who will also give the necessary instructions about its mode of employment. It consists essentially of a platinum-pointed pencil kept at a high temperature by means of the ignition of benzine or of benzoline blown upon it by means of an air blast. The blast is supplied by means of bellows worked with the foot, or the common double globular pneumatic apparatus, operated by the hand. The air thus pumped passes through an indiarubber tube into a bottle containing the benzine, and forces a spray of the latter out through a second tube into the hollow platinum-pointed pencil. According to the intensity of the blast, the temperature of the pencil point will be greater or less, adapted to fainter or blacker lines. The bottle is never more than half filled with spirit, and when not in use must be tightly corked. The left hand produces the blast, while the right hand is engaged in tracing the design. Two points are required: one for lines and dots, another for backgrounds and deep shadows. The poker points must be kept in movement; if allowed to rest upon the wood, a hole will result. The poker is held very diagonally when working, and is moved indifferently in all directions. The outlining and the grounding lines must meet each other. The work when finished may be stained and polished, or varnished at discretion. French polish can be used, or white, hard spirit varnish, or mastic, or copal varnishes. There is scarcely a limit to the designs, or to the articles of domestic use that may be done by means of poker work, and in clever hands very artistic results are obtainable. But go to Barnard's, just now mentioned, and you may also write to Abbott Brothers, Southall, for prices.—J.

**Model Engine.**—F. D. (*Devonport*).—I cannot do better than ask your attention to the series now running through WORK, entitled, "How to Make a Quarter Horse-Power Engine." By reducing the dimensions there given, you can get a cylinder of a very pretty type, and there is ample information given as to the fitting up, which is equally applicable to smaller as to larger cyliuders.—J.

**Tempering Tools.**—A CONSTANT READER.—Tools for working granite are hardened and tempered at one operation—that is, they are not let down like metal-cutting tools. There are various plans made use of, the endeavour being to impart exceessive hardness combined with some degree of toughness. In every case the tools are heated to a dark cherry red, and quenched at once and for good in a medicated liquid, in which salt, alum, and nitrogenous substances are dissolved. Thus for one: Take half a teacupful of salt, ½ oz. of saltpetre, and a teaspoonful of alum, and dissolve in rain or soft water. Another: Take six quarts of salt water, 1 oz. of corrosive sublimate, 1 oz. of sal-ammoniac, and three handfuls of salt, and dissolve. Another: Take two gallons of rain water, 1 oz. of corrosive sublimate, 1 oz. of sal-ammoniac, 1 oz. of saltpetre, 1½ pints of rock salt, and dissolve. Another: Take three gallons of water, 3 oz. each of ammonia, white vitriol, sal-ammoniac, spirits of nitre, and alum, and 6 oz. of salt, with two handfuls of horse-hoof parings.—J.

**Glass Case.**—F. G. (*Liverpool*).—Presuming you want a plain case for your model, you cannot do better than make up a framework of wood into which the glass can be fitted either with putty or with wooden strips of beading. As an alternative you may run the glass into grooves ploughed in the wooden framing as suggested in the accompanying illustration, which represents a portion in section.—D. D.

Section of Framing of Case.

**Invalid Chair.**—J. H. (*Glasgow*).—It will be necessary for you to supply more information as to the kind of invalid chair required before details for its construction can be given. There are so many kinds of chairs or seats for the afflicted that many might be described without meeting your wants. You might say, for example, whether it is wanted merely for sitting in, reclining in at variable angles, or in a fixed position; whether it is to be used for carrying an invalid up and down stairs, and if sanitary conveniences are an essential feature, with any other particulars which occur to you. It may be remarked that unless you are an expert, which presumably you are not from your asking directions, you would find it impossible to make a satisfactory article, unless of the simplest character. It would also probably cost you more to make than to buy. To judge from your letter, I am inclined to think you want an Ilkley couch. Is this so?—D. D.

**Arrangement of Cuttings.**—NESCIENCE.—I know of no "cheap and handy method of arranging or filing or binding . . . cuttings and scraps on various scientific subjects of all sizes and shapes," but one, and that is to select a size of sheet such as may be most convenient to you—say folio in your case—and paste down the longer articles on single pages, and the shorter scraps in kindred groups on pages set apart for the reception of cuttings on particular subjects. Number your sheets; prepare as full an index as possible; and when you have filled sufficient to make a volume, have the volume bound. In doing things of this kind you must depend, as lady novelists do, on inner consciousness of what is necessary, and from this evolve a method of meeting your own special requirements.

**Propeller for Steamers.**—E. F. B. (*Liverpool*).—You do not, by your own admission, understand the construction of a "modern high-speed steamer," and yet you "have an idea of a new (quicker and cheaper than the old) method of propelling steamers." I have heard a great deal about new propellers of late years, but no good results have come from any of them. Under the circumstances, be content to leave the matter to experts, who are trying all they know to devise propellers that will drive a ship through the water faster than any that are now in use.

**American Watch Movements.**—J. SHAW.—All American movements have a pin projecting from the edge of the plate, and this pin fits in a small hole in the rim of the case; pass the pin in this hole, holding the movement face upwards, then press the movement well down into the case, turn the case over, and screw the dog-screws half a turn, to grip the case tight. Swiss movements are fixed in the case the same way; but they have usually three pins, one of which is filed half away, and this one goes in a notch; the other two go under the edge; press down the movement, turn the case and movement over, and give the dog-screws a turn round to hold it in.—A. B. C.

**Straining and Mounting Water-colour Tracings.**—A BINDER.—It is difficult to handle these by the damp process, unless the colour is mixed (in use) with gum or a weak isinglass size to fix it. If very carefully treated the tracing may be maintained by steam from a kettle, of course holding the back to the steam spray, then just paste the *edges only* for ¼ in., and lay down. The other and the easiest way is to provide a strainer, similar to those used for oil paintings, and nail down your calico, then wedge out your strainer. These strainers can be purchased for a few pence of any dealer in artists' materials.—F. B.

**Wardian Case.**—W.P. (*No Address*).—A design, with practical instructions for making up the same, is in the hands of the Editor, and will appear as soon as the pressure of other subjects will allow.—C. M. W.

**Waterproof Leather.**—PLUMBER, *alias* A READER.—The above question was answered in WORK, page 413, column 1, of "Shop."—W. G.

**Making Hand-sewn Boots.**—S. E. (*Battersea*).—There have not as yet been any articles in WORK on hand-sewn boot making; but there is a series in hand which will I hope, set you right. The actual thing of your being able to make riveted work will greatly enhance progress in the above, for you have commenced at right end, and the comfort of wearing band-sewn boots will well repay you for your study and trouble in the future. I hope you have followed up my articles on "Repairing," now appearing, the last of which will soon be published, and as it is on soling and welting hand-sewn boots, it will teach you a lot that you wish to know, as these were intended (although of practical use for the moment) to be a preliminary to the more important set, "Making." There is a book on boot and shoe making, and several touching the subject; but I would not advise you to buy them, for they are very dear, and touch, not one, but all subjects of boot and shoe manufacture. They are written almost expressly for technical students—in fact, they are only technically practical, and not what one might call practical, pure and simple. In fact, that is why I write practical matter, with hints on some of the most simple points, for I myself, years back, needed such instructions, and therefore know others must, in rising, do the same, and not the science of a trade that they know not yet the rudiments. The previous answers in "Shop" ought to have been of great use to you, as you are so far advanced. If you have not an index of Volumes I. and II., you should get them (1d. each). You would see at a glance every number that has anything in it connected with your requirements.—W. G.

**Liquid for Curling Hair.**—F. R. (*Sunderland*).—It does not come within the scope of WORK to furnish information of this kind. Moreover, no liquid will curl your hair. You must resort, as others do, to curling-irons, curling-pins, or curling-papers.—ED.

**Staircasing and Handrailing.**—J. W. C. (*Tavistock*).—Articles on these subjects are now being prepared by a competent hand, and the first will appear in the next volume of WORK.—ED.

**Architectural Draughtsman.**—J. W. C. (*Tavistock*).—It is not possible for me to tell you now where you may get a post of this kind. Why not advertise in WORK, and so catch the eye of some of the many employers who read WORK?

**Fittings for Rocking-horse.**—RAWTENSTALL.—For eyes, RAWTENSTALL might apply to Messrs. Donziger & Isaacs, Beadmakers, Frederick Street, Birmingham; or, better, to Messrs. E. Schramm and Co., 33, Pershore Street, in the same town; but as these wholesale houses would scarcely care to supply a single pair, we would rather advise RAWTENSTALL to go to the nearest taxidermist. Hair for mane and tail can doubtless be bought from Mr. W. Brabe, Horsehair Manufacturer, Moseley Street, Birmingham. For the priming material with which to coat the body, RAWTENSTALL had better apply to the nearest carver and gilder, who will supply him; but should this be impracticable, he might prime with a mixture of gold size and yellow ochre, pumicing each coat down, when dry, till a sufficiently level surface is obtained.—S. W.

**Wheel of Life.**—J. F. (*Tipton*).—The exact size of wheel in the zoetrope is immaterial—perhaps one having a diameter of 1 yard would be found efficient; 4 in. square might be given as dimensions for the pictures. The slots must be so large as to enable the eye to take in one picture at a time as the wheel revolves—say, 1 in. long by ½ in. wide. Smaller slots require the eye to be brought closer, larger ones make it necessary for the eye to retire. Clark's zoetropes were, we believe, smaller than the above dimensions—the diameter of wheel being 18 in. or 24 in. Clark's, Garrick Street, London, W.C., was formerly the best place to get pictures for the zoetrope; but we are not sure that the business is still carried on; perhaps J. F. had better try E. Schramm & Co., 33, Pershore Street, Birmingham.—S. W.

**Glass Lamps and Paper Lanterns for Decorations.**—LISFARRON.—We should advise you to go to Messrs. E. Schramm & Co., 33, Pershore Street, Birmingham.—S. W.

**Working Models.**—W. D. (*Wigston Magna*).—Probably Messrs. E. Schramm & Co., 33, Pershore Street, Birmingham, would be able to supply the sheets of illustrations which you require for cutting up to make these things. These would doubtless come from Germany, and the above German firm import all matters connected with toys.—S. W.

**Dolls for Ventriloquists.**—VENTRO.—Try Messrs. E. Schramm & Co., 33, Pershore Street, Birmingham; if unable themselves to supply what you want, they will doubtless be able to point out some house that can do so.—S. W.

**American Organ.**—H. W. (*Southampton*).—I regret to say that the contemplated papers on the American Organ cannot possibly appear in the present volume of WORK.

**Folding Sheets for Work.**—H. W. (*Southampton*).—There are no plates or illustrations published with the monthly parts of WORK that are not included with the weekly numbers.

**Book-keeping.**—NESCIENCE.—We know of no work on book-keeping having special reference to manufacturers' accounts beyond the one you mention, namely, Garck and Fell's "Factory Accounts."

**Advertising.**—G. K. (*Ramsgate*).—Your idea has been anticipated and carried out at various seaside resorts during the summer.

**Glass Case for Minerals.**—ROB ROY.—A cabinet for specimens of natural history will appear shortly.

**Ticket-writers' Ink.**—BRIEF.—Replies to correspondents on "Ticket-writers' Ink" appeared in Nos. 24, 38, 46, and 74 of WORK. This information might have been gathered from the indexes to Vols. I. and II., which can be obtained for 1d. each through any bookseller or newsagent.

**Staircasing and Handrailing.**—N. B. (*Eltham*).—Articles on these subjects will appear separately in Vol. IV. of WORK.

**Engraving on Metal.**—N. B. (*Eltham*).—You will obtain the information you require with regard to engraving, the tools that are used, and how to sharpen them, from the papers on this subject, by Mr. Norman Maclean, in Nos. 33, 38, 40, 43, 45, and 48 of WORK.

**Carpenters' Bench.**—J. V. H. (*No Address*).—Replies are not, and ought not to be, forwarded by post to correspondents. It appears, however, that the contributors did so. Stamps sent in letters do not reach the Editor's office, and are not forwarded by contributors. All letters sent from editorial offices are duly prepaid by the Company. When correspondents send a stamped and addressed envelope, it is generally returned to them with a notification that replies cannot be sent by post.

**"Work" Exhibition.**—E. M. B. (*Withington*).—There will be no renewal of the "Work" Exhibition this year.

**French Polishing.**—G. T. (*Bow*).—Articles on this subject have recently appeared in Nos. 105, 108, 115, 117, 119, 122, 123, 126, and 130 of WORK.

**Strips of Beaded Mahogany.**—S. N. (*Southsea*).—Apply for these of Messrs. Henry Zilles & Co., 24 and 26, Wilson Street, Finsbury, E.C., who will no doubt be able to supply something that will meet your want.

**Corner Bookcase.**—NOVICE.—A bookcase to stand on a corner cupboard would be practically useless to you and everybody else. You will find a good "Corner Bookshelf Fitting" in Vol. I., page 561; otherwise, No. 36 of WORK; but not even the central compartment of this would stand on a corner cupboard unless the cupboard were abnormally large.

**Co-operative Inventive Association.**—Inventors may like to know that an Association, Limited, under this name, exists at Newcastle-on-Tyne.

**Safety Bicycle.**—G. I. (*Lower Broughton*).—Articles on this subject have recently appeared in Nos. 107, 111, 115, 119, 124, 127, and 132 of WORK.

**Expanding Envelope.**—J. P. W. (*Bristol*).—You must submit your envelope to a practical maker. I cannot undertake, under any circumstances, to advise inventors with regard to their inventions.—ED.

**Bedroom Suite.**—W. J. (*Portsea*).—No, I cannot undertake to give you "A design and details for a bedroom suite with a duchess dressing-table and drawers, and washstand with a marble top and towel-horse, with two drawers in dressing-table and one each side of looking-glass, and turned legs for both washstand and dressing-table." Have you any idea how many pages of WORK it would take to give you designs, etc., that would be practically useful to you?—ED.

**Dulcimer.**—P. J. (*No Address*).—You say you "wish to make a good dulcimer." Well, carefully follow the instructions given in the series of articles in Vol. I., and I see no reason why you should not succeed as well as others have done. Ample instructions are given in No. 41, p. 646, for stringing, and the diagram on p. 645 of the same number shows the correct way of tuning. For the rest, I think I had better take your questions *seriatim*. (1) It is found that four or five strings to each note give the best effect, less than this giving a thinner and weaker tone. (2) The degree of softness is regulated by the performer. If a very soft tone is desired, the beaters must be covered with several layers of Berlin wool or other material, and the player himself must exercise his judgment in using them. (3) Any ordinary tune can be played on the instrument, but music of a quick and lively character is the most suitable. (4) The introduction of "more semitones" would only have the effect of confusing the scale and rendering it more difficult to play; as it stands, it is a very easy instrument to learn, and not much knowledge of music is required. (5) It can be tuned to the harmonium, and the two played together make a very pretty and effective combination. (6) Hardly requires an answer, but as there are only twenty bridges on the instrument, it must be obvious that only twenty pieces of wire will be required for them, and that, consequently, forty is an error.—R. F.

## III.—QUESTIONS SUBMITTED TO CORRESPONDENTS.

**Fretwork.**—E. B. (*Dorsetshire*) writes:—"I should be glad if some kind reader could tell me of an address where I could dispose of fretwork brackets, cabinets, etc."

**Model Steam Launch.**—A. M. C. (*Holywood*) writes:—"Will any reader of WORK kindly tell me how to make a model of a steam launch, and where the best place would be to get engines for same?"

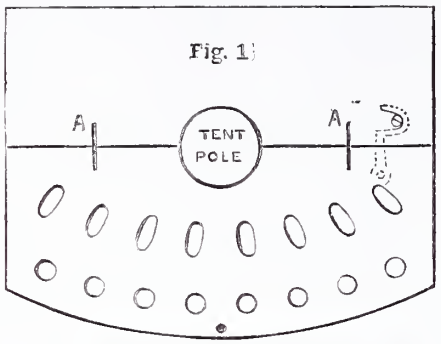
**Ebony for Walking-sticks.**—J. P. (*Hollinwood*) writes:—"Can any correspondent kindly inform me where to buy black ebony for walking-sticks in Manchester?"

## IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Carvers' Tools.**—PROFESSIONAL writes, in reply to J. D. (*Tiverton*) (see page 631, No. 91), asking for the addresses of makers of the above:—"For straight tools, Addis, Arctic Works, Sheffield; bent gouges, T. Beddall, Malvern Hill Road; Nechells, Birmingham."

**Carbon Plates.**—W. C. H. (*Godalming*) writes, in answer to J. H. (*Wolverhampton*) (see page 254 of current volume):—"You can obtain carbon plates, 2¼ in. by 1¼ in., for box battery, as described by Mr. Bonney, at 2s. 6d. per dozen, or 3d. each; also tapped and drilled zincs for same, 2¼ in. by 1 in., at 2s. 6d. per dozen, from Mr. H. Fentum Phillips, Electrician, Stoke, Guildford. He makes amateurs' work a speciality, and is moderate in price."

**Rifle Rack.**—P. W. (*Devonport*) writes, in reply to A. S. (*London, S.E.*) (see page 331, No. 125):—"I enclose a rough sketch of a rifle rack which I made to take eight carbines. I find it very useful in camp, and think it is something like A. S. asks for. It is very simple, light, and portable. To make it, get two pieces of mahogany board 16 in. long, 7 in. wide by ⅞ in., cut a hole for the tent pole in the centre of the joint, as shown in sketch, and around the front bore eight holes (as shown) the size of the muzzle of the rifle, and get eight plugs turned, as at B, to fit in the holes and down into the muzzle, which will keep the rifle in place. I have a piece of fringe around the front, as shown at Fig. 2, which hides any irregularity in the muzzles not being exactly level, as the ground may not be



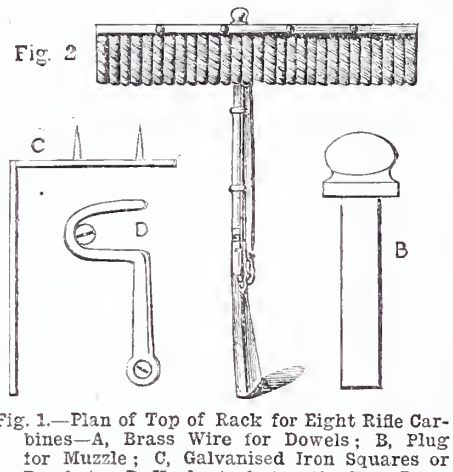


Fig. 1.—Plan of Top of Rack for Eight Rifle Carbines—A, Brass Wire for Dowels; B, Plug for Muzzle; C, Galvanised Iron Squares or Brackets; D, Hooks to fasten the Two Parts together underneath. Fig. 2.—Elevation, showing Carbine standing in Place, and Fringe round Top of Rack.

even. By simply lifting the plug you can immediately free the rifle you require without moving the other seven. The other eight holes at the back of the plugs are to take the swords, which I pass down through the top of the rack into the scabbards underneath. By so doing I do not require the holes so large, and the top is not weakened by having large holes cut in it. Two squares are screwed under the top, close to the tent-pole holes, and are lashed to the pole. The back half serves for a shelf for brush and comb, etc. etc. The two hooks hold the two parts together, and are screwed under the rack. In fixing, it should be 1 in. higher than the length of rifle, as the pole will settle, especially in soft or sandy soil. One or two sconces for candles can be fixed, if desired."

## V.—BRIEF ACKNOWLEDGMENTS.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—F. M. G. (*Glasgow*); E. J. (*Belfast*); GAS-LIGHTER; E. R. D. (*Sherborne*); NEWLAND; W. F. B. (*Rochester*); G. P. (*Tunstall*); R. S (*Darwen*); RAILWAY; J. B. (*Sowood*); A. M. W (*Dublin*); A. R. (*Birmingham*); J. H. (*Smethwick*); A. W. (*Leicester*); W. W. (*Sussex*); T. T. (*Darlington*); H. R. K. (*Bedford Park*); A CONSTANT READER; J. T. G. (*Norwich*); SLIDE RULE; C. Y. H. (*Smethwick*); T. H. T. (*Blyth*); J. W. W. # A WONDERFUL MEDICINE.

# BEECHAM'S PILLS

Are universally admitted to be worth a Guinea a Box for Bilious and Nervous Disorders, such as Wind and Pain in the Stomach, Sick Headache, Giddiness, Fulness and Swelling after Meals, Dizziness and Drowsiness, Cold Chills, Flushings of Heat, Loss of Appetite, Shortness of Breath, Costiveness, Scurvy and Blotches on the Skin, Disturbed Sleep, and all Nervous and Trembling Sensations, &c. &c. The first dose will give relief in twenty minutes. This is no fiction, for they have done it in countless cases. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

**Worth a Guinea a Box.**

FOR FEMALES THESE PILLS ARE

"A priceless boon, a treasure more than wealth; the banisher of pain, the key to health."

These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the nervous and debilitated is,

***BEECHAM'S PILLS have the Largest Sale of any Patent Medicine in the World.***

Prepared only by the Proprietor, T. BEECHAM, St. Helen's, Lancashire, in Boxes 9½d., 1s. 1½d., and 2s. 9d. each. Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*

## "The Amateur."

**Pattern Sheets of Fret, Carved, and Inlaid Work. Painting on Wood, and other Similar Domestic Arts.**

*Terms of subscription*:—5s. per annum; 2s. 6d. half-yearly; or 6d. monthly, of all booksellers.

*Complete Catalogue Nos.* 38, 39, & 42, *of Artistic Fretwork, Carving, Inlaying, and Wood-Painting Designs, Machines, Tools, Mouldings, Cabinet Fittings, etc., with* 1,500 *Engravings*, 6d.

Having more than a million customers in England and the British Colonies, booksellers will not only find it easy, but also remunerative, to push "The Amateur" wherever the English language is spoken.

HENRY ZILLES & CO.,

# AIR PUMPS AND THEIR CONSTRUCTION.

BY O. B.

INTRODUCTION—VACUUMS UNKNOWN—KINDS OF AIR PUMP—PISTON AND BARREL PUMPS—JOINTS—VALVES—PISTONS—IMPROVED PISTON—DOUBLE STROKE—SOLID PISTON—IMPROVED DOUBLE PISTON—MERCURY PUMP—SPRINGLE'S PUMP—PERFECT PATTERN—GEISSLER'S PUMP—SUTTON'S PUMP—WATER ASPIRATORS—MAWSON AND SWAN'S MODIFICATION IN BRASS.

*Introduction.*—The advances which have been made in late years in electric lighting and other departments of physical experiment and investigation have rendered air pumps of the highest efficiency an absolute necessity. It is the purpose of the writer to offer such observations as will help the amateur to succeed in his various operations.

*Vacuums Unknown.*—It may be taken for granted that to produce an absolute vacuum is an impossibility as far as our efforts are concerned, for if even all air and vapour of water could be extracted from a containing vessel, it is highly probable that vapours would be thrown off from the material of which the vessel was made.

Still, though an absolute vacuum may be impossible, yet air, etc., may be reduced to such tenuity as to prevent the passage of electricity; for it is a misconception to suppose that a perfect vacuum is needed in an electrical vacuum tube; a certain quantity of attenuated matter is necessary to render the energy visible.

*Kinds of Air Pump.*—Air pumps may be broadly divided into two classes: First, those in which a cylinder and piston are used; and secondly, those in which the falling of a fluid is made to entangle portions of air.

*Piston and Barrel Pumps.*—Of these there are various kinds: such as the single-action barrel (Fig. 1). This, if carefully made, is fairly efficient.

*Joints.*—The three points to pay especial attention to are: first, joints. To make good joints with solder may seem very simple, but where air pumps are concerned it is really not so. I have known days spent by professional workmen—and they, too, makers of scientific instruments—in the endeavour to find a leak, and, after all, were baffled. The plan the writer has adopted is to place the parts under water and force air into them. A leak is shown by a bubble. Another point to attend to is to boil the work in water in which soda has been dissolved. If any kind of soldering fluid is employed, and a portion is left in any crack or crevice, it will be sure to corrode, and eventually make a leak probable.

*Valves.*—Secondly, valves. The holes should not be larger than will admit a dress pin; indeed, it may be said the smaller they are the better. On the edge there must be no burr or sharpness that can, by possibility, cut the silk. A general idea of a valve is given in Fig. 2. The tube, A, is turned down, and a screw thread is chased on it at B. A disc, C, $\frac{1}{4}$ in. thick, is carefully soldered on the end; this is under-cut as shown. In the centre a fine hole is drilled. The end of the disc must be made perfectly true, without the suspicion of hollowness; too much attention cannot be paid to this, as if the silk does not lie perfectly close to the disc it cannot be air-tight. Two sides of the disc must now be cut away, as shown at D. The edges must be carefully smoothed and a strip of oiled silk, *a c*, must be drawn over the end and carefully tied, as shown. Due attention must be paid to the quality of the silk; in fact, no portion of the work must be performed carelessly, for in vacuum apparatus most certainly the strength of the instrument is only equal to its weakest point.

The action will be easily seen when a vacuum is made in the barrel; the air in the receiver expands and passes under the silk. As soon as the piston returns and the pressure is greater than in the receiver, the silk is forced on the disc, and the return of air is prevented.

*Pistons.*—Thirdly, the piston. This, as made and applied in the ordinary pump, is very inefficient, as when the air in the vessel is reduced to a given rarity and flows into the barrel, it cannot be compressed sufficiently to overcome the pressure of the outside atmosphere, and so cannot force open the outer valve.

*Improved Piston.*—But there is another method which may be adopted, and the wonder is that it is not always used, as the valve is mechanical, and independent of the pressure of the atmosphere.

Fig. 3 is a sectional diagram. The under side of the piston, A, is faced with a disc of rubber, B. The rod attached to this is a hollow tube, E; C is a disc of brass in which are drilled four or five holes, as at G. To this disc is securely fastened the rod, D, small enough to work in the tube carrying the piston. This rod is fastened to the cross-handle, and is $\frac{1}{8}$ in. longer than the tube in which it works.

We will suppose the piston is at its lowest point. In pressing it down the disc has been forced away from the piston, and the air in the barrel has escaped through the pin-holes and by the hollow piston-rod. As soon as the handle is drawn up, the disc beds on the rubber sole of the piston and connection with the outer atmosphere is cut off. In the vacuum thus formed the air rushes in from the vessel, and the action is repeated. This is a very great improvement over the ordinary method, in which there is always a residuum of vapour which cannot be compressed sufficiently to overcome the pressure of the external atmosphere.

*Double Stroke.*—The barrel and piston may be modified in various ways: such as a double stroke, in which the valve leading from the receiver is placed midway between the extreme ends of the barrel (Fig. 4), by which means exhaustion is produced at each stroke. At B, B′, are stuffing-boxes, through which the piston works. At *e*, *c*, *d*, are silk valves.

*Solid Piston.*—Fig. 5 is a modification of this plan, only here is a piston one-half the length of the barrel. By this means the valve, *e*, is dispensed with. In all other respects it is similar to Fig. 4, though perhaps it is needless to say that its action is not so rapid. There is also a further well-known method, viz., the pump with two vertical barrels and pistons worked by rack and pinion action.

*Improved Double Piston.*—Fig. 6 is an instrument I have designed, being a modification of one designed some years since by a Mr. Turton, which, as far as I am aware, has never been taken up in a commercial way, or received the attention it has deserved. We have seen already that the one great drawback in the ordinary pump is that the residual portion of air becomes so rarefied ultimately that it cannot be compressed sufficiently to overcome the pressure of the outer atmosphere. When this condition is obtained no further exhaustion can take place

By the arrangement here shown this difficulty is minimised to a large extent. The barrel, B, is in communication with the receiver, and the small barrel, C, communicates with B. At *a* and *c* are valves which open into the respective barrels, and at *d* one for the expulsion of the air. The action is as follows: Let the piston of C be raised to its full height. The piston of B is now to be used until the receiver is so far exhausted that the rarefied air can no longer open the outer valve, *d*. The piston, *c*, is now forced down; but as the barrel is so much smaller than B, the residual air can be correspondingly compressed, and a portion forced out. When raised, there will be a comparative vacuum left, into which some of the residual air can be pumped until the atmosphere in C becomes so dense that the air from the large barrel can no longer force open the valve, *c*. The piston in C is now forced down, and compresses the atmosphere so much that it is equal to overcoming the resistance at valve *d*, and is again raised, forming a vacuum. This process goes on, working the alternate barrels until the atmosphere becomes so rarefied that no further exhaustion can take place, which will be much more complete than by the ordinary method. In the construction of a pump on this plan, the one point to be remembered is that the smaller the area of C is as compared with B, the better, whilst an obvious advantage will be gained by making C as long as possible. The longer it is the more air it contains; the smaller in the bore it is the smaller will be the amount of residual air left in it when the piston is forced down.

A convenient, and at the same time a workable, size would be large barrel, 2 in. diameter by 6 in. high; the smaller, $\frac{1}{2}$ in. by 12 in. high.

By this means, when B has exhausted the receiver to a point where the residual air could no longer overcome the outer valve, it can be further compressed sixteen times, as the area of C is only $\frac{1}{16}$ that of B, and thus the rarefaction can be further carried on.

*Mercury Pump.*—Besides the various modifications of the barrel and piston described, there is another class of apparatus in which the piston is a stream, either of mercury or water. As the piston is always moving in one direction, the difficulty arising from the incompressible residuum found in the barrel of the best model we have described is done away with. There is no valve to open, and the vacuum can be carried on until an electric spark will not pass.

Of mercury pumps there are various types, though they all start from the same central idea.

*Springle's Pump—Simple Pattern.*—The one most generally known is the Springle. Figs. 7, 9, and 11 are various modifications. Fig. 7 is the most simple. It consists of a glass tube of small bore, and 40 in. long. One end opens into a funnel; about 2 in. from this, a tube is placed at right angles. This is also bent at right angles, so that its outer end is parallel with the main tube. To the short tube is attached the vessel to be exhausted. Mercury is poured into the funnel, which must be kept full. As it flows it forces the air before it, causing a partial vacuum. The air in the vessel expands, and entering the tube, a portion of it is forced onwards. This process is carried onwards, resulting in a very perfect vacuum. Fig. 9 is another form. The vessel to be exhausted is attached to the stem A.

*Perfect Pattern.*—In Fig. 11 we have the same instrument expanded to its perfect

form, which yields the most perfect results attainable.

The tube, T, should be about 50 in. long, $\frac{3}{4}$ in. bore; A is about the same length, and $\frac{4}{5}$ in. bore. Tubes K, $K^1$, are 47 in. long and $\frac{4}{5}$ in. bore. At the bend they are expanded somewhat: with a funnel fused as shown. D is a globe, such as can be procured at most chemical and laboratory stores, having three openings. A tube of fine bore, $\frac{1}{15}$ in., is bent as shown, into which is fused the funnel, $f^2$; $p$ is a short length of tubing bent to right angles, and fused into the globe; B is the same bore, and 58 in. long. In the two funnels, $f^1$ and $f^2$, glass stoppers are ground, or else corks which have been thoroughly soaked in paraffin-wax must be used. The tubes A and K are connected by strong indiarubber tubing. For this purpose bicycle cement should be used. Strong tape, with one side dressed with the cement, must be wound round the tubing: this will give the necessary resistance to the pressure of the mercury. $K^1$ and T must be joined in the same manner. The waste-pipe, W, must be joined by a short length of rubber; also the funnel, $C^1$, to the tube, $d$. The vessel to be exhausted is attached to the tube, $p$. Under B must be placed a vessel to receive the mercury as it flows. To use the apparatus, proceed thus: Strong spring clips are placed at $C^2$, $C^3$, and $C^4$. Pour mercury into the funnel C until T is nearly full. Remove the stopper, $f^1$, also the clip, $C^3$, and pour in mercury until $f^1$ is nearly full, when replace the stopper with the mercury flowing round it, thus sealing it. Further sealing may be effected by pouring water on the top of the mercury. Clip $C^4$ is now removed, when the mercury will rise in A, leaving a vacuum in the bulb at K K′, where will accumulate any air which may be contained in the mercury.

As more mercury is poured in the funnel, C, the funnel, $f^2$, will fill, driving all air before it, when it must be sealed as the other. The mercury will now fall through the bulb, D, into the tube, B, in the form of drops. So much air having been removed from the bulb, the air in the vessel expands, and again fills the bulb. The next fall of mercury forces another portion out. For a while the portion of air between each succeeding drop will form a cushion; but when the exhaustion is complete, the mercury will fall with a distinct click or knock, showing that there is no film of air between the separate drops, and that its work is complete; exhaustion can thus be carried on until the air in the vessel to be exhausted is only $\frac{1}{1000000000}$ of its original quantity.

*Geissler's.*—This (Fig. 8), for complexity, stands midway between the extremes already described, whilst for efficiency it is all that can be desired. D is a shelf for holding a bulb, A, with three openings. At B is a funnel with a ground glass tap. At C is a tube with a similar appliance. At D is attached a strong rubber tube in the manner already described. The lower end of the tube is joined to a jar containing mercury. To work the instrument, fasten the vessel to be exhausted to the tube, C, and close the tap, K. Open the tap, H, and raise the bottle, G, until the mercury fills the bulb as well as the funnel. Now close the tap and replace the bottle on the stand; the mercury will fall in the tube, leaving a vacuum in the bulb. Open the tap, K, when the air will rush in from the vessel and fill the bulb. Now close K and open H, and fill the bulb with mercury as at the first, and again exhaust it by lowering the bottle. Each time this is done a portion of air is removed, until at last, when, with both taps closed and the bottle raised, the bulb fills with mercury, we know the exhaustion is complete.

*Sutton's.*—Fig. 10 is an instrument which bears the name of Sutton, which is somewhat less complicated than Fig. 11, and at the same time all that can be desired in the way of efficiency. The illustration will almost explain itself. B is a glass tube which develops into a bulb. It should measure not less than 36 in. from the lower bend to the point where the tube, F, joins it. G is a tube of about $\frac{3}{4}$ in. bore, terminating with a funnel, L. Into this are fused the tubes, F and I. The tube, G, is filled with small lumps of pumice-stone or fibres of asbestos which have been dipped in sulphuric acid. This is for the purpose of absorbing any moisture. Each end of the tube is to be secured by a stopper, either of ground glass, or cork prepared as already described. The funnel is now filled with mercury; a glass vessel is placed so as to contain the lower end of the tube. This, too, contains mercury; by these means the tube is securely sealed. C is an iron vessel with its inside accurately bored and fitted with an iron piston. A strong tube of rubber connects the cylinder to the tube, B. At K a vessel is placed to receive the overflow mercury. To use the instrument, proceed as follows: attach the vessel to be exhausted to the tube, I. Force the piston down until the mercury rises in the bulb and fills the tube, J. Now raise the piston to its original position, when the mercury will fall out of the bulb, leaving the bulb vacuous, the mercury at the same time rising in the bent tube, J, until it balances itself to the atmospheric pressure. The mercury must be allowed to fall in the tube so as to be just below the point where F joins it. When this point is reached the air rushes in from the vessel to be exhausted, filling the bulb, at the same time causing the mercury to sink in the bent tube, J. It may be observed that the bending of this tube forms a trap, as, though air can be forced down, it cannot of its own accord rise up the tube and pass the mercury, seeing its gravity is so much less than the metal. When the inrush by the tube, I, has been made, the piston is again pressed down; the mercury rising above M at once seals the communication with the vessel to be exhausted, and, filling the bulb, expels the air by the tube, J. This is to be continued until the vessel is exhausted, which will be manifest when the mercury forced over ceases to be separated from the preceding portion by a cushion of air, and the column is continuous.

For the tube, B, a bore of $\frac{1}{8}$ in. will be sufficiently large, whilst for the tubes, J and F, the ordinary barometer tube should be used. By the use of these appliances gases can be so rarefied in vacuum tubes that the electric spark fails to pass, for want of a medium dense enough to conduct it.

*Water Aspirators.*—This article could hardly be considered complete if no reference was made to apparatus in which water is used in the place of mercury. The principle of construction is similar to those given. Whilst they are very useful in the laboratory for many purposes where a high vacuum is not required, yet for some purposes they are useless.

*Mawson and Swan's.*—Messrs. Mawson and Swan, well-known makers, have introduced, however, a pattern which is very effective. It is exceedingly simple in construction, and, consequently, inexpensive. As its price is only 4s., it would hardly pay anyone to attempt to make one, unless it were for the love of making, which is an instinct with all true amateurs.

*Modification in Brass.*—As sold by the firm mentioned, it is made in glass, though it might easily be made in brass; the extra cost and labour would be balanced by its greater strength and non-liability to be broken.

The diagram (Fig. 12) will give a correct idea of its construction. A is a tube of brass into which is soldered the tube, B, which is to be attached to the water-main. C is another tube to which the article to be exhausted is attached. At the juncture of these tubes, $a$, a perforated disc is soldered, to which is joined a fine bore taper tube, F, as shown. D is a tube composed of two cones joined at their apex and soldered to tube G. E is a tube to which is attached the waste-pipe, and is joined to G at $b$. G and A are joined at $c$. This will quickly produce a vacuum capable of sustaining a column of mercury of nearly the full barometric height. As sold by Messrs. Mawson and Swan, the instrument is much more simple than it appears in brass, and quite as efficient; but the hints I have given are for those who prefer to make their own instrument, but are unable to work in glass.

All the screwed joints in the above instruments must be made air-tight with white lead.

## STAGE PERSPECTIVE.

BY WILLIAM CORBOULD.

### Interiors: their Perspective, and how to Outline them.

We will take a square room first, drawn in parallel perspective, supposing the spectator to be standing in front and looking into the centre of the room. (See Fig. 7.) The vanishing or points of measurement in this case, on the imaginary horizontal line, B B, are $a$, $a$. The point of sight, $c$, would be the vanishing point where all lines must fall into. The line $d$ $d$ is the base or commencement of the floor; a line drawn from each corner at $b$, $b$, to the vanishing point, $c$, would give the base of each side of the room, $f$, $f$; by the same rule, lines drawn from the top corners, $e$, $e$, to the point, $c$, will give the top of the sides, or the ceiling lines. Draw lines from the corners, $b$, $b$, to the points of measurement, $h$, $h$. Where these lines cross, base lines, $f$, $f$, would come, the two upright lines forming the further sides of the room. The top and bottom lines, $g$, $g$, complete that side, or the back wall of the room. Point A is the spot where the spectator stands.

The reader of these rules will observe that the points of measurement, $a$, $a$, in all the drawings extend beyond the square lines of the rules laid down. This brings the scene well within the circle of 60°. It will be seen also that you get greater breadth and boldness, as the top and bottom lines will not drop or rise too suddenly. When the points, $a$, $a$, are brought in closer to your work, you would see the difference. It would dwarf your work. On the other hand, the further you keep the points of measurement, the opposite is gained—*viz.*, breadth and boldness. Supposing you were painting a scene which took up all the space of the room or stage you were painting on, and you could not get your measurement point on the horizontal line beyond the square of your scene: place a dot a little above and one a little below the horizontal line. (See $h$, $h$, Fig. 7.) You will

see that all lines passing through those dots would fall into the points, *a*, *a*. It will be seen at once that the further apart the dots, *h*, *h*, are the broader and higher would be the room.

Fig. 8 shows an interior drawn in oblique or angular perspective. It will be seen by this rule that the base or floor lines are drawn—one from the right corner, *b*, to the vanishing point, *a*, on the left of the horizontal line; the other from the left corner, *b*, to the vanishing point, *c*, which is the point of sight. You will see this point of sight is shifted from the centre a little to the right. By doing this, you raise the height of the wall in the corner of the room, giving greater breadth and height to the walls of the room. By the same rule, if you shift the dot, *c*, to the left, you will get greater length, which you may want to do at times. Lines drawn from each corner, *e*, *e*, to the same points, *a* and *c*, will give the ceiling lines. When a cornice is shown, those lines would start inside, according to the width of the cornice, as at *d*, *d*. All lines on the right side of the room would fall into the left-hand point, *a*, while all lines on the left side of the room would fall into vanishing point, *c*. Bear in mind, these lines are such as dado, mantelpiece, doors, windows, pictures hanging on the walls, etc. A little practice and judgment will soon make it easy.

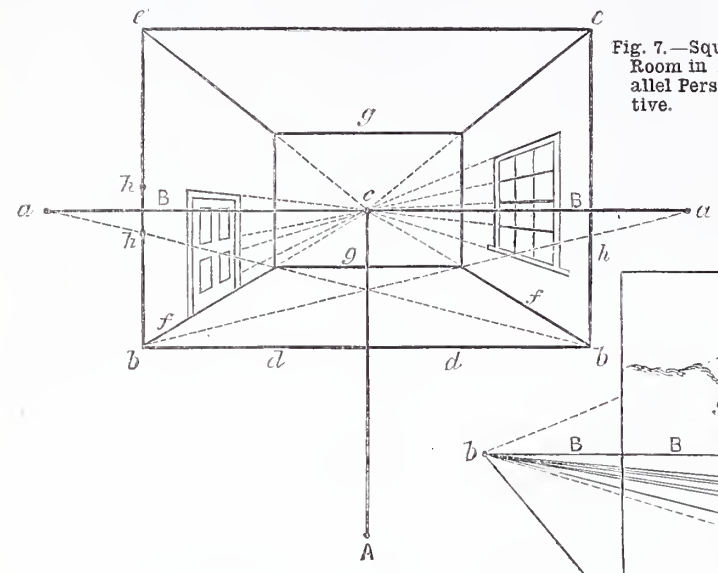

Fig. 7.—Square Room in Parallel Perspective.

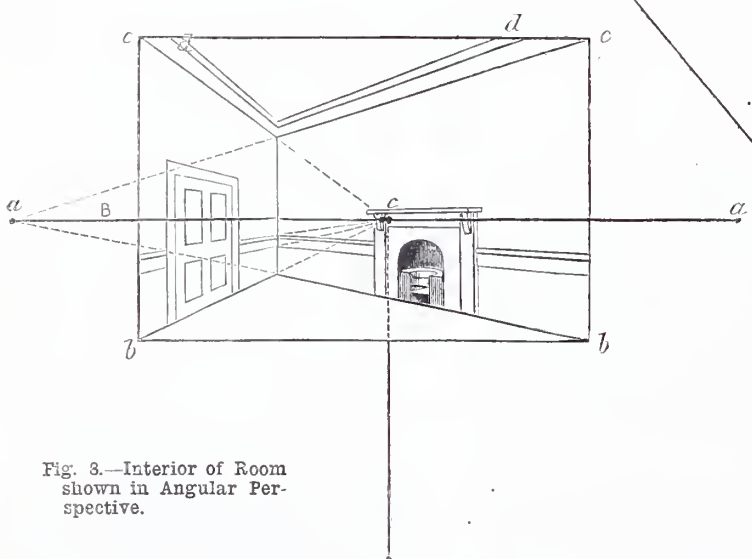

Fig. 8.—Interior of Room shown in Angular Perspective.

Fig. 9 is also in oblique or angular perspective, and shows the way to draw a bridge or aqueduct. Just draw your horizontal line, B B; then the point of station, A, fixing this a little to the left of the centre. It will be seen that the line drawn from A to *a* on the horizontal line is longer than the line drawn from point, A, to measuring point, *b*. I have mentioned this again to show the difference between parallel and angular perspective, as these lines may all be imagined. When the artist has mastered the rule, having decided upon where your bridge shall start from, you erect your first upright line, *c c*; divide this line in half, as at *e*; draw a line from *e* to measuring point, *a*. You will find the use of this line further on. Now draw your geometrical scale, *d d*, from the bottom of your first perpendicular line. You lay out the breadths of the several arches and spaces between them on this line. Say the arches are 10 ft. and the piers 3 ft. Dot out the distances on the geometrical line. If lines are drawn from these several dots to vanishing point *b*, it will give the perspective breadth and depth of the arches and piers, as where these lines cross the ground-line, *b b*, will be the spot to erect the perpendicular lines, *o*, *o*, *o*, *o*, *o*. Should the bridge or aqueduct have more than two arches, you probably would not have room to lay out more than two on your geometrical line; therefore, you must adopt another simple plan. This is where the line from dot *e* to point *a* comes in useful. It will be seen that the lines marked *h* when drawn the first one from *c* to *c*, cut line *e* exactly where the second perpendicular line rises from the ground-line, *b*; given the perspective width of the first arch, as laid out on the geometrical scale, the next line from *o* to *b* gives the second arch; the two lines in front of the two first, which we have just drawn, gives the width of the piers. You will now see that after the first two arches are drawn how easy it is to get the rest, by continuing the diagonal lines through each pair of arches where it intersects the centre line, *e*, with each and every perpendicular line, drawn from where the previous diagonal line comes in contact with the ground-line, *b b*; a line drawn from dot *g* to measuring point, *a*, would give the apex of each arch. I might show other lines, such as those indicating the parapet and ornamental parts of the bridge, but this is not requisite, because if the pupil will study the rules of perspective which I have laid down as simplified as possible, he will soon overcome any difficulty he may have to contend with at first, and he must always remember and bear in mind that perspective is the grammar of art.

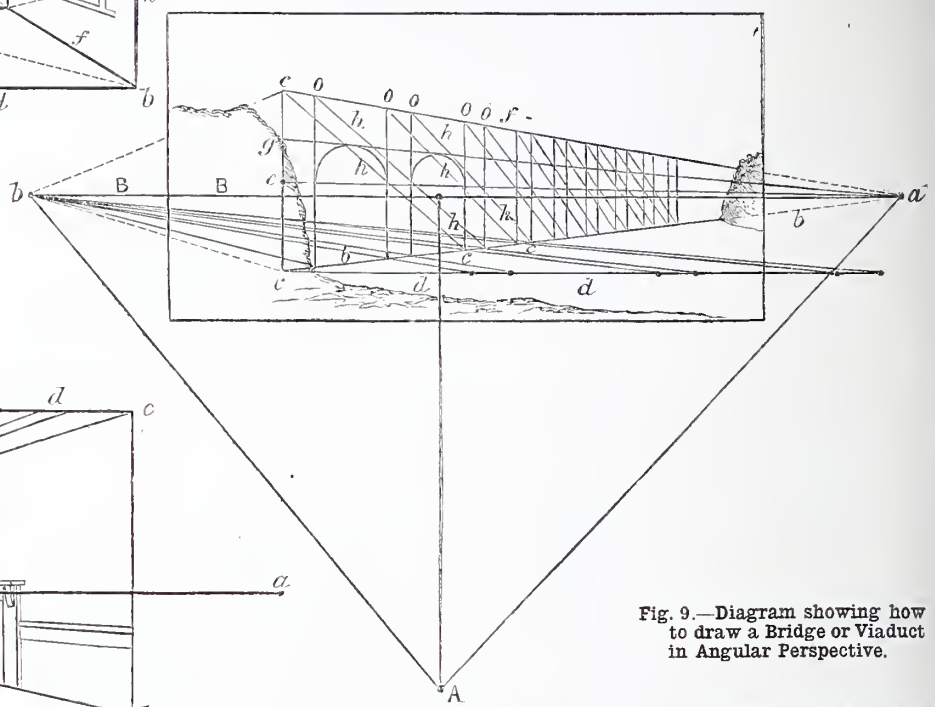

Fig. 9.—Diagram showing how to draw a Bridge or Viaduct in Angular Perspective.

## HOW TO MAKE A QUARTER HORSE-POWER STEAM ENGINE.

BY F. A. M.

### The Main Shaft Bearings and Connecting-rod.

Fitting the Brasses without Filing—Turning up the Pins on Upper Brasses—Filing up the Bearings and Fitting the Caps—Turning the Outside of Brasses—Chucking the Bearings and Boring them out—Turning the Connecting-rod—Carrier for Turning Square Bars—Fitting Small End Brasses—Or Hard Steel Bushes—The Large End Brasses—Bringing the Hole true with that of the Small End—Re-centring the Rod—Filing up Forked End.

Let us now take up the angular crank shaft bearings shown in Figs. 8 to 11 (page 328), as well as in Figs. 4 and 5 (page 260). It is not very easy to fit the brasses into an ordinary bearing, but these bearings are arranged so as to require as little filing as possible. The brasses are not square or octagonal outside as usual, but round; and therefore they can be turned and their seats can be bored. Lest, however, they should turn in their seats, the

upper brass of each pair has a pin cast on it, which fits into a hole in the cap, and both prevents all danger of turning and conducts the lubricant down to the journal, without allowing any of it to escape, as it may in the usual form of construction, between the cap and brass. We have two castings of iron for each of the two bearings and two of brass, or rather gun-metal—a harder kind of brass. Begin with the two upper brasses, which we must chuck for turning the round pins. Rub each of the four brasses upon a file so as to bring up their two edges flat and smooth, and make them semi-circular; take the two upper ones and centre the round pins with the centre punch and drill; put a bit of wood in the lathe and face up the end, which should be about two inches in diameter; lay the half bearing on this and bring up the back centre point to enter the centre hole in the pin, advancing the point till the little casting is firmly held. The pin to be turned is so small that this pressure may be sufficient to hold it against the action of the tool (see Fig. 47); but if not, two nails, *a*, *a*, can be driven into the end wood, so as to ensure that the brass shall turn with the wood. Having turned the pins on both the upper brasses, tin the edges of the two pairs of brasses, and put them together edge to edge, in pairs; heat till the solder melts and they are united. They can now be smoothed out inside with a file till the inside of each pair is fairly smooth, and then they are ready to be chucked by the hole whilst they are turned to 1 in. diameter outside the body (Fig. 11) and on the inner sides of the flanges; but this cannot be done just yet. Lay aside the brasses and take up the two bearings and their caps. File up the soles of the bearings so that they will stand upright and square with the plate; file the sides of the bearings, bringing them to $\frac{3}{4}$ in. in thickness (Fig. 8). Now fit the caps in: the opening where they go measures 1 in. It must be as much as that, or the bearing brasses could not be put in, but it would not hurt if it were a little more, provided only that the caps fit well, without shake. Fit the $\frac{1}{4}$ in. screws that hold down the caps, provide nuts, and bolt it down; file up the sides of the caps level with the sides of the bearings. The reason for filing the sides of the bearings true first, is, that then the sides of the opening for the caps can be got square with the flat sides of the bearings. Now file the under-sides of the caps, both under the ears, or lugs, and under the edges of the projection, so that they will stand up square on these surfaces. There is now an oblong projection under the caps measuring 1 in. by $\frac{3}{4}$ in., and we can chuck them by this so as to bore the $\frac{7}{16}$ in. hole exactly in the centre of this projection. Chuck a piece of hard wood, turn it about $2\frac{1}{2}$ in. in diameter, and face it up; make a recess $\frac{1}{2}$ in. deep, and enlarge it gradually till you can press the projection of the cap into it with the fingers: this will centre it truly. Now pass a couple of wood screws through the screw-holes in the ears to secure them to the wood chuck; starting it with a graver, bore a $\frac{7}{16}$ in. hole, into which the pins on the upper brasses can fit easily. Treat the other cap in the same way. We may now go back to the brasses,

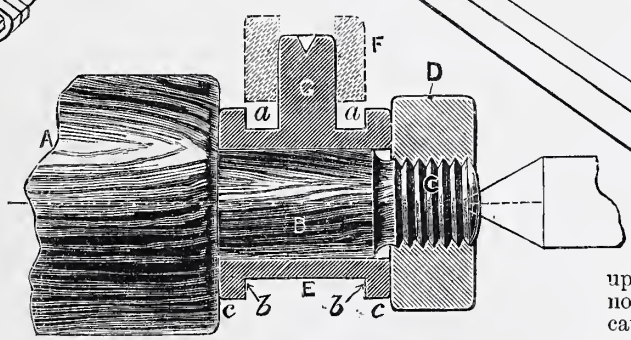

Fig. 48.—Mode of chucking the Brasses.

which we left soldered together in pairs, the pins being turned and the holes being filed out fairly round. Unfortunately, we cannot drive them on to a mandrel to turn them because that would burst them apart; we must therefore adopt another method of holding them. Make a chuck of hard wood (Fig. 48), A; turn down a pin, or short mandrel, B, on which the brasses, E, can fit; cut a screw, C, on the end, and fit a nut, D, so that the brasses may be pinched between the nut and the shoulder of A, and held without any tendency to burst asunder the soldered joint. A rather easier way would be to cut off the pin, B, where the screw begins, and, instead of a nut, have a bit of flat wood to receive the back centre point and transmit to the bearings the pressure of the back centre screw; this does away with the necessity for cutting screw, C, and its nut, but it is not so good a plan, because the point of the back centre will gradually indent the bit of wood, and diminish the pressure on the bearing, which may then turn round on the pin and require to be trued up again. The plan shown at Fig. 48 will not relax its hold, and, if the cutting is carefully and cautiously done without catching against pin G, the necks, *a*, *a*, can be turned to exactly one inch in diameter, the outsides of the flanges, *c*, *c*, to 1¼ in. in diameter, and the inside edges of the flanges, *b*, *b*, can be turned true. In doing these last, the cap, F, would be tried on to the turned pin, G (see Fig. 48), and the flanges turned away till the cap will just go down between them when put over the pin. It is much easier to *turn* the inside of these flanges true than to *file* them. The caps and the tops of the pins of the brasses should be marked so that the caps may not be exchanged nor turned half round, since, if the hole in the caps were not absolutely central, they will not fit both ways. Now, though we have turned the bands, *a*, *a*, true on each side of the brasses, there is a band $\frac{7}{16}$ in. wide in the middle which cannot be turned on account of the pin; it will, however, be very easy to cut this down level with the two side bands with a little sharp chisel and files, and so make the rest of the outer surface almost as true as if it had all been turned.

We must now return to the bearings. Fit on their caps, screwing them firmly down; then take the face-plate and angle-plate we used for boring the crosshead. If the angle-plate has not been moved, it will be in exactly the right position for boring the bearings, since their centres should be 1¾ in. high, the same as before; if the angle-plate has been taken off, it can easily be replaced by means of the same little template (Fig. 40, page 420). Bolt the bearings upon the angle-plate one at a time, so that their sides shall be exactly parallel with the face of the plate, standing up perpendicularly from the top of the angle-plate. To test your work, bring up a tool and let it touch the circular facing, on bearing and cap, as it goes round, when it should touch equally, or nearly so, all round. Now bore out the seat for the brasses to 1 in.; take off the cap and try the brasses in. The flanges have been fitted to the sides of the cap, and the cap has been filed to the same thickness as the bearing, therefore the flanges of the brasses should fit the bearing equally well; they should require a little gentle rapping to drive them down into their seat: it would be very bad indeed to have them loose. Having got one pair of brasses down solidly on to their seat, put on the cap and nuts, screw them down, and bore out the brasses to ¾ in.; face up the front of the brasses, and round the corner at the mouth of the hole. In Fig. 5 these corners will be seen dotted; looking at the crank shaft, where it passes through the bearings, it is seen reduced from ⅞ in. to ¾ in. in diameter; but shafts of this kind are never cut into by a square corner, but always by a little quarter circle, which leaves them much stronger. Now, therefore, we must round the corner of the hole in the brasses to a little quarter circle of $\frac{1}{16}$ in. radius. This done, and the other bearing put on the angle-plate and treated in the same way, we must re-chuck them in a reversed position so as to face up the other side of the brasses; turn them half round on the angle-plate, and adjust till the hole in the brasses runs true, and the face of the bearing is parallel with the face-plate; then face the brasses and round the corner with a $\frac{1}{16}$ in. quarter circle as before. Now warm the brasses till they come in two, mark them carefully and their bearings, drill the oil hole in the pin, and tap it for the lubricator, when the bearings may be laid aside for the present.

Here it should be remarked that success in fitting a bearing of this sort depends very much on *the order* in which the several operations are performed. Order, or sequence, is always of importance, and should be carefully considered before a piece of work is begun.

The connecting-rod may be undertaken next; it appears in Figs. 4 and 5, uniting the crosshead and the crank, and also in Figs. 12 to 15 (page 328), where its ends are shown in detail; it has been left till now partly because it is perhaps the most difficult part of our work. The difficulty lies in the necessity for having the holes through the brasses at the two ends exactly parallel. Begin by centring the connecting-rod and putting it into the lathe; the forked end will admit the lathe centre between the forks, and the carrier can be of the kind used to hold upon a square. A sketch of this sort of carrier, which any amateur can make for himself, is given at Fig. 49. It is simply formed of two pieces of flat iron, A, A, A, held together by two screws, B, B; C is the connecting-rod end, seen in section, and D is the pin of the driver chuck. Having then chucked the rod, turn the body, leaving it tapered from $\frac{9}{16}$ in. at the large end to ⅝ in. at the small, and nicely polished with emery-paper. Turn up the oblong flange at the large end facing the end square, and scratching upon the end surface two short arcs of a circle 1¼ in. in diameter, on which to mark the centres of the bolt-holes. The only parts now remaining of the large end of the rod not got up bright are the sides of the end flange, and these must be filed up with reference to the small end of the rod. Lay the rod down on the surface-plate so that it rests on the fork at one end, and on the end of the flange at the other (see Fig. 50). A is the face-plate, B the rod, and C the square. The edges, *c*, *c*, of the end of the rod must be filed up square with the small end, but this can only be done if the depth of both the eyes, *d*, *d*, are equal. Having tried the surfaces, *c*, *c*, with the square, we file little flats under each eye for the rod to rest on—which little flats will be useful as guides hereafter—and in filing them we may take a trifle more off one eye than the other, so as to bring *c* and *c* upright, if it be not so already. Now file up *c*, *c*, making the flange a little over ⅝ in. wide, so as to allow a little for after correction, but bringing both surfaces square and parallel; then turn the rod over and file two other little surfaces on the other sides of the eyes, so as again to bring *c*, *c*, vertical; this will make the distances, *d*, *d*, at D, equal. Draw a line with the scriber point down the centre of the flange at *f f*, to determine the centres of the bolt-holes, and centre-punch the intersection of this line with the arcs marked with the lathe tool. Looking now at Fig. 51, we have two little flats on each eye, *a*, *a*, *b*, *b*, square with the flange at the other end of the rod; we need, however, two other guide surfaces (*c*, *c*) before we can attack the octagonal hole for the brasses, and these surfaces are obtained by standing the rod up vertically upon the plate and filing the surfaces, *c*, *c*, till the rod stands straight up as tested by the square. When this is done the three surfaces can be used as guides for filing out the octagonal holes; distance *a* to *b* being 1⅛ in., then the thickness of metal from *a*, *b*, and *c* to the adjacent side of the octagon will be ¼ in. In order to mark the lines *d d*, *d d*, at right angles to the length of the rod, put a bit of wood under the end, at D, Fig. 50, so as to bring the rod horizontal and level with the plate; then these lines can be marked with a scriber by squaring up from the plate. Lines *e e*, *e e*, too, can be drawn at the same time with the scribing block. In filing out these holes the little square file will pass through both eyes at once, so that it must run straight, and the lines *d d*, *e e*, will be marked on the outside of both eyes; then, by taking ⅛ in. in the callipers, and making that the thickness of the metal inside each of the little guide surfaces, we can hardly fail to get out the holes correctly. Lines *f*, *f*, can be drawn with the scriber by means of an ordinary set-square (for drawing) of 45°, resting on the face-plate, whilst the rod is packed up level by means of the bit of wood. Now take the four little castings provided for the brasses of this end, and, rubbing their edges upon a file, tin and join them in pairs with solder. Now take each little couple and rub on a file, so as to get up one side true and level from which to work; then begin with two opposite sides of the octagon—say those which fit against *e e*, *e e*—make these square with the first face, parallel with each other, and leave them just so far apart that you can almost push the brass into the hole sideways. Fig. 52 will make this plain. The brasses being only $\frac{5}{16}$ in. thick, and the top and bottom sides of the octagon a little more, it is possible to try the two first sides of the brasses in that way; but as the octagon is not a true one, but somewhat elongated, the other six sides being shorter than $\frac{5}{16}$ in., we cannot try the other sides of the brasses in, and must trust to careful measurement until they will begin to drive in a little way, when the shape of the hole in the rod will get marked on them, and they can be filed accordingly, keeping every side square with the first face and making sure that they fit tightly so as to require a little gentle driving to get them in. Having fitted the two pairs of brasses into the forked end of the connecting-rod, we may proceed to bore the hole, or rather enlarge it, to the size for the crosshead pin by means of the ⅜ in. fluted reamer. Begin by passing through the holes a small round file, using it very carefully so as not to get the hole askew; enlarge it gradually, stopping continually to measure with callipers from the hole to the three test surfaces. As soon as the ⅜ in. reamer will enter, use it to round the hole and measure again, then correct with the file if needful. Of course, it is very important that both sides of the fork should bear equally on the crosshead pin. To ensure this, test still further by

turning a little iron mandrel, about 4 in. long, to the same taper as the reamer, so that it will fit into the holes where the pin goes (see Fig. 53); then turn a bit at each end to, say, $\frac{1}{4}$ in.; now pass this mandrel into the two holes and stand the connecting-rod up vertically on the face-plate. Now you can measure from the plate up to the small diameter ($\frac{1}{4}$ in.) at each end of the little mandrel to prove whether the mandrel is perfectly parallel with the plate and therefore square with the length of the rod. If not, ease the hole inside with the file, and round it again with the reamer. The reamer must finally be worked into exactly the right distance so as to make the hole about the same size as that in the crosshead; the pin should, however, fit more easily in the brasses than in the crosshead, in which latter it should be driven pretty tight, and further secured with the set-screw. The brasses then being driven into their places in each side of the fork, and the hole for the pin being finished, we must cut the two little slots for the cottars or wedges which tighten the brasses. Looking at the section of the crosshead in Fig. 5, the cottars are seen cutting into the brasses; this is to keep them in place, and it would prevent the fork end of the connecting-rod from slipping sideways. This, however, is already prevented in our case by the crosshead fitting between the fork, still it may serve to keep the brasses in place when the rod is taken off. These little holes must be cut by drilling from both sides and finished with small files and much patience. The cottars should be of steel, and may be hardened and spring tempered.

Here I may say that it would be easier, and perhaps as efficient, to insert hard steel bushes or ferrules in the fork ends, and to harden the crosshead pin instead of fitting the brasses and cottars. True, there is no means of taking up wear in that case, but the movement of this joint is very small, and, if both bushes and pin are hard, the wear will be almost inappreciable; moreover, it is always possible to make a new pin and to insert new hard bushes. To fit the fork end this way, we should have to file out the octagonal holes, round, in connection with a $\frac{3}{4}$ in. fluted reamer, using the same precautions to ensure the hole being square with the rod which have been described when the hole in the brasses was being adjusted. The crosshead pin would be made of cast steel, and hardened; the steel bushes would be bored slightly small, turned on a mandrel, hardened, driven tightly into place, and then ground out by working an iron or brass rod with emery and oil through both bushes while in position in the rod end, the iron or brass rod being turned to exactly the same taper as the crosshead pin.

We must now complete the large end of the connecting-rod as seen in Figs. 13, 14, and 15 (page 328). Unite the two brasses with solder as before described, and file up the end surfaces parallel with each other; mark the positions for the bolt-holes and bore them; make the little oblong cap of steel and bore similar holes in it. By means of these bolt-holes, the brasses, with the cap, can be secured to the angle-plate on the face-plate of the lathe whilst the hole in the brasses is bored out, faced, and the corners, seen at Fig. 13, rounded. The next operation will be to bore the holes for the bolts in the end of the rod; one of these holes may be bored first and the bolt fitted; but, before we bore the other, we must take certain precautions to ensure it being so placed that the hole through the brasses at both ends of the rod shall be parallel. The bolts to secure the large end brasses should be of mild steel, and the nuts should be hardened; the holes they fit in should be cleaned out with a $\frac{1}{4}$ in. taper reamer. The bolts are shown in the drawing with the heads inside and the nut outside, which looks best, but necessitates the reamer being put in from the rod side, which is not very convenient; however, the reamer may be put in from the cap end, and the bolts may also go in that way if preferred; the body of the bolts should be turned to fit well into the holes. To ensure the holes at both ends of the rod being parallel, and not, as carpenters would say, "in winding," fit two turned rods into the holes, using them as winding strips, the cap and brasses of large end being secured by the one bolt first fitted. We have already fitted a small mandrel to the small end of the rod (see *m*, Fig. 53); the small end of the rod may be supported on this by means of the two small strips, *s*, *s*, which are of equal width; the other end of the rod rests on the face-plate. Now, when the larger mandrel, M, is fitted into the brasses at the large end, it will be easy to see whether M is parallel with the plate; if not, the brasses can be slightly twisted on the one bolt till it is so. When they have been correctly adjusted the bolt may be firmly secured and the $\frac{1}{4}$ in. drill put through the cap and brasses to bore the remaining hole in the rod, then after cleaning it out with the reamer the second bolt may be fitted. We now require a centre at the top of the cap by which we can turn the whole rod. This can be found by resting the rod on two similar V's, or angles, standing on a level surface, on which the rod can be turned round. This will be easily understood by looking at Fig. 54, where the complete rod is seen lying on two V-pieces; lines are scribed across the top of the cap at ×, the rod being turned partly round between each line, taking care not to move it endways in the V's. These V-pieces may as well be of wood for this purpose, nailed together and cut out both at once; but a pair of cast-iron ones, carefully made, are very useful things for centring rods for the lathe, etc. Having found the centre, as nearly as may be, and made a dot with the centre-punch, the rod may be put in the lathe and brought true with the square centre, then the rounded edges of the head of the rod, brasses, and cap may be turned up and finished, when it only remains to drill a hole for the lubricant, starting from the centre hole just found, through cap and brass; enlarge this hole and tap with $\frac{1}{4}$ in. thread in the cap, and it is ready for the lubricator; then the sides of the flanges can be filed up, and the large end of the rod is finished. The fork end must now be filed up; the four flat surfaces through which the hole for the crosshead pin passes must be accurately at right angles to this hole or the joint cannot work. We can attain this by using the crosshead pin as a guide. Observe in Figs. 5 and 8 how the head of the pin abuts against one of the sides of the fork; file that side flat first and test it as you do so by inserting the pin with a little red marking under the shoulder; do not be satisfied till the red marking shows equally all round the hole, then you may be sure the first surface is square with the hole, and the other three surfaces can be filed parallel with it by means of callipers. Though, however, the first surface may be square with the hole, before we proceed to file the second or left-hand side surface to it, we must lay the rod on the V's with the finished side up, and, with the scriber, measure from the plate up to that surface; then, after turning the rod round, measure up to the second surface to try how much will have to come off to bring the rod central; also, whether, when both these two first surfaces are parallel, square with the hole, and equally distant from the centre line of the rod, the fork will measure $1\frac{5}{8}$ in. from side to side, according to Fig. 8. When all these conditions have been complied with and the two outer surfaces have been finished, the two inner ones, which embrace the crosshead guide, may be filed parallel with them, using the callipers to bring them to exactly $\frac{5}{16}$ in. thick. Now it will only remain to file up the top and bottom of the fork and round the end, take out the three pairs of brasses and separate them where soldered, and the connecting-rod is done at last.

The writer is much afraid he may have wearied his readers by going into such detail, yet though he is well aware that too much has been said to please some, yet others may still wish for even more particulars. All directions as to the use of files and other tools will be spared the readers of these papers, and only those points insisted upon which seem likely to prove stumbling-blocks to those who are already fairly proficient in handling the tools themselves. Though much time and space have been given to the connecting-rod, the directions given are such as should throw light upon fitting in general, and may be useful even to those who never attempt to make such a thing as a $\frac{1}{4}$ horse-power steam engine. Having, however, got thus far in our work together, we have overcome the most important obstacles, and both work and description may perhaps proceed somewhat more quickly from this point.

## TWO FOLDING BOXES:

### WITH LEGS ADAPTED TO USE AS COMBINED TRAVELLING CASE AND TABLE.

BY J. SCOTT.

"THERE is nothing new under the sun." These words are constantly ringing in the ears of the designer, and no doubt there is a great deal of truth contained in them. But I think I may venture to say that, in the boxes shown in my illustration, I have succeeded in producing something that is new, novel, and useful.

Personally I prefer box No. 2; but, as No. 1 may probably be mostly admired, I have considered it best to give them both.

Who has not, at some time of removal, found the inconvenience of packing up the small odds and ends—things that seem nothing when lying scattered about on tables, shelves, and in cupboards? Boxes may be provided for the time being, but they eventually become as great a nuisance as they were previously an assistance. These boxes, then, supply a want in this direction, and they will also be found handy as travelling cases.

I have also given illustrations of some suitable legs, so that when these boxes are folded they can be made to serve as table-tops.

Very little skill is needed for making these articles. The putting on of the hinges will perhaps be the most trying part, seeing that one box has eight pairs, and the other six pairs. But it must be remembered that,

if it were not for these hinges, we should not be able to stow our box away into so small a compass.

The size I have represented Figs. 1 and 2 as is 2 ft. square by 1 ft. deep. Of course, they can be made larger or smaller, and of a different proportion; but I shall only proceed to describe the size I have given.

For Fig. 1, then, we require six boards, each 1 ft. wide by 2 ft. long, and one board 2 ft. square. All these boards should be of the same thickness, either ½ in. or ¾ in., according to the strength required.

The large and side boards require canting on the edges all round, so that when any two of them are placed edge to edge they will stand at right angles to each other. The other two boards should each have three of their edges canted, leaving one long edge on each free to receive the fastenings.

Through the four boards, which will form the sides of the box, holes should be bored, large enough to admit of the free movement of a thin rope. These holes would be best if they are bored on the angle, following the line of the rope, instead of being bored straight through.

When all the boards are ready, place them in their proper position, and mark off where the hinges are to go. The two top pieces should be hinged on to the two sides to open *outwards;* these sides, in their turn, should be hinged to the bottom of the box, to shut *inwards.* The two remaining sides will require hingeing on to the bottom, to open *outwards.* The fastening on of the lock, and the placing of the rope, require no commenting upon.

Fig. 2 now occupies attention. The size of each separate board varies slightly from those of Fig. 1, although it is exactly the same size when expanded.

We need two boards, each 2 ft. long by 1 ft. 11 in. wide; two more, each 1 ft. 11 in. long and 11½ in. wide; and four, each 2 ft. long by 6 in. wide. The only parts that require canting on these pieces are the two edges on the *width* of the bottom board, and the bottom edges on the inside of the two ends. The top edges of these ends will each need a lock.

The hingeing of these boards will be a more "ticklish" job than in fastening those of Fig. 1 together. It will be found best, I think, to hinge two of the narrowest pieces together first. These form one side, which will need to be hinged to the bottom and top boards, so that it will fold inward. Then hinge each of the other two narrow pieces in a corresponding position on the opposite side to the bottom and top. The two ends will then require to be hinged to the bottom board, to open outward. It will be found an easy matter then to fix the two remaining hinges.

It will be necessary to have handles fitted to some part of this box. These should be sunk in the same manner as that adopted in an ordinary travelling trunk, so that they will not prevent the boards from folding flat together. The rope will be found sufficient for box No. 1.

Box No. 2 may be made exactly 2 ft. square each way, by making the four side pieces, which fold in together, 12 in. wide each, instead of 6 in.; and by making the end pieces 2 ft. by 1 ft. 11½ in., instead of 2 ft. by 11½ in.; and by fastening one to fold over on to the top, and the other to fold under the bottom. This will necessitate the top and bottom boards respectively to be canted on one of their edges only.

Now we come to the legs, by using which the box can be made to serve as a table. In Fig. 3 we have four legs, each 27 in. long, 1½ in. square at the top, and gradually tapering down to 1 in. square at the bottom. Four pieces of ¾ in. stuff, 1½ in. wide and 15½ in. long. Also four pieces of ½ in. stuff, 1½ in. wide at the centre end, and 1¼ in. at the outer end, which are fastened to the legs.

The square centre blocks should be 1½ in. square and ¾ in. thick. The turned piece which is joined between these two squares may be of any length, but I should advise 13 in. long and 1 in. thick. The longest wooden strips are for the top, and should overlap the legs by about 1½ in. It will then be found that the weight of the folded box will be sufficient to keep the legs from collapsing.

Perhaps it will be said that there is too much hingeing on these legs. But, of course, in giving publicity to the design I do not compel the reader to make an article accordingly; and, so that it may not be said that it is a matter of "Hobson's choice," I have also given the design, Fig. 4, which requires nine hinges instead of sixteen.

The longest pieces of wood shown in Fig. 4 are 30 in. long, by 1½ in. wide at the top and 1 in. at the bottom. The three pieces on to which the table-top rests are 10 in. long and 1½ in. wide. The other three pieces are 1½ in. wide at the top end and 1¼ in. wide at the bottom end. Both the ends of these last three pieces should be canted, so as to allow them to fit nicely to the other parts when used as a table support.

The triangular block in the middle of each leg will have to be very firmly put on, as a great weight will rest on them.

The triangular centre-piece will be 2½ in. wide on each side. As the legs, when folded, come underneath this block, it will be found necessary to cant them on their inside edges. The thickness of all the wood used in Fig. 4 should be ¾ in.

Perhaps it will be best to fasten all the hinges on to the thickness of the wood.

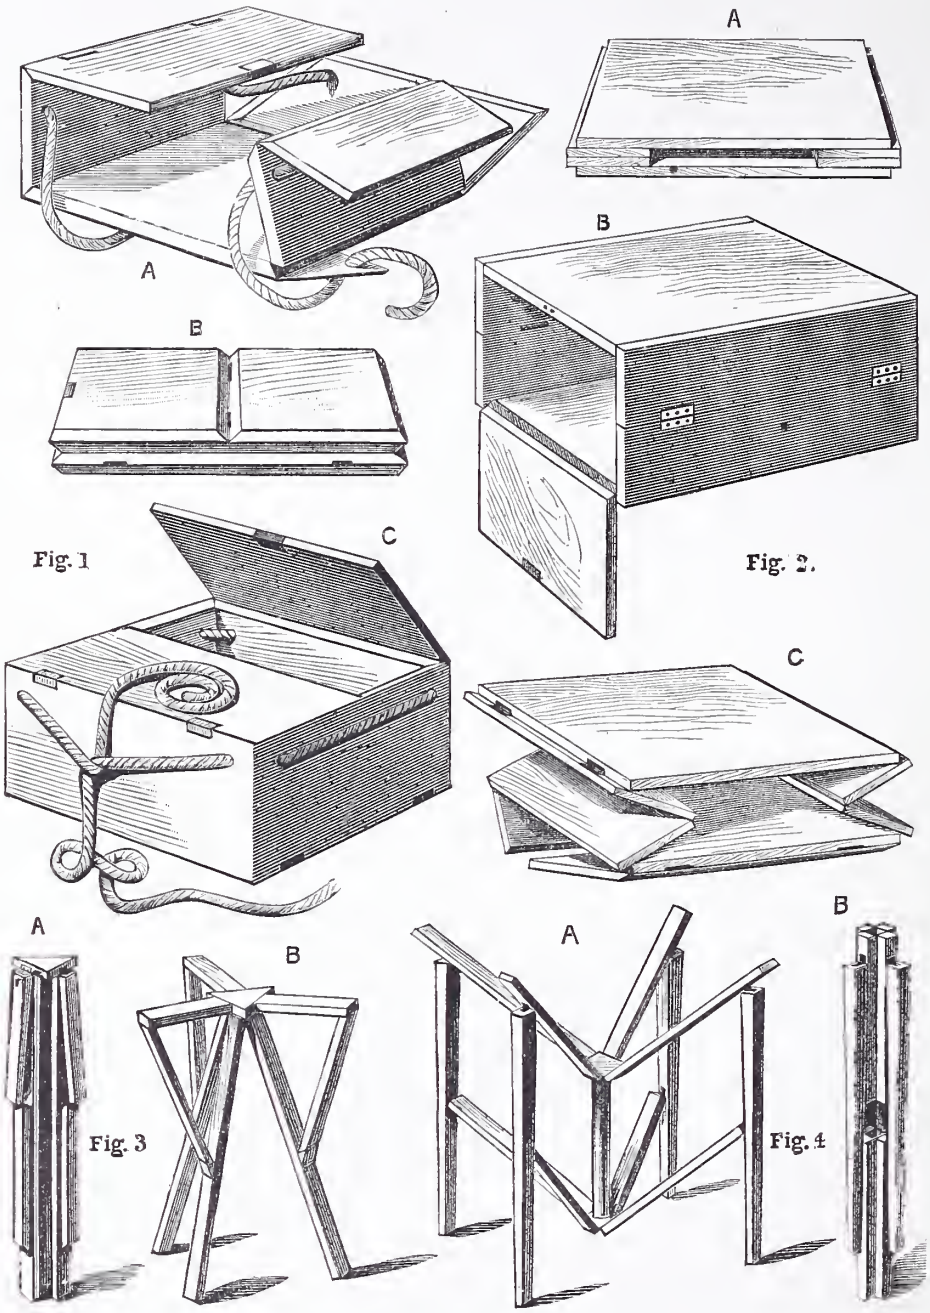

Fig. 1. Fig. 2. Fig. 3. Fig. 4.

**Fig. 1.—Method of folding Box (A), Box folded (B), and Box ready for Use (C). Fig. 2.—Box folded (A), Box ready for Use (B), and Method of folding Box (C). Fig. 3.—Legs forming Stand for Box, folded (A) and unfolded (B). Fig. 4.—Ditto, expanding (A) and folded (B).**

None of them will show them. The same with fixing the hinges on the box. If a little judgment is used none of them need be exposed to the eye.

I have represented them as fastened on to the surfaces of the wood, so that thereby I might indicate the position of them, and show in which way the wood is to fold.

I think there is nothing so boring as to read certain statistics, such, for instance, as the number of miles Mr. So-and-so's bank-notes would reach if placed end to end; or the height Mrs. So-and-so's sovereigns would attain if placed one above another, but at the risk of being termed a bore, I will give just one or two statistics of these boxes.

Two hundred and two 4 ft. square and 2 ft. deep boxes, standing one above the other, would reach as high as the top of St. Paul's—which I have always been given to understand is 404 ft. high—but when folded they would only occupy a space of 4 ft. square by 33 ft. 8 in. high.

Again, ninety of them, 2 ft. by 1 ft., filled with articles, would fill a pantechnicon van 10 ft. long by 6 ft. high and 6 ft. wide; but when compressed together the pile would be but 1 ft. high. I give these figures to show to what use these boxes may be put with advantage.

## A PATENT RUBBER FELLOE WHEEL.

BY JOHN C. KING.

About two years ago an article in the *Saddlers' Gazette*, on the use of rubber in carriages, received the tribute of appreciation by transfer to foreign journals. Here is something coachmakers have long sought for—a hard-tired, perfectly round-rimmed wheel, suspended in rubber, free from contact with the ground.

A shrewd man of experience remarked that "the merit of using rubber in carriages was at present not very great: plastering it on the sole of an iron-shod wheel, or wedging a piece of it between spring and axle—the one to wear out quickly as well as augment draft on good roads; the other, to produce a loose bearing where a tight one was wanted."

He rode on a vehicle with the rubber protected by a tire, as illustrated, and further remarked—"Here is successful genius—applying rubber in so small a quantity as to be economical and in such a manner as to be indestructible, while effecting its purpose of saving riders from traffic noises (and the street dwellers also), and relieving the shoulders of the horse from the effects of wheel concussion with road obstacles, and, above all, saving the rider's spine, heart, and brain from jars incidental to hard-tired vehicles."

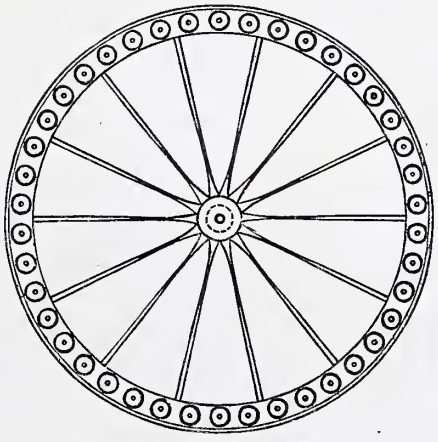
It will be obvious that the rubber ring felloe wheel is a spring wheel within a rigid circular hoop, the rings at bottom forming flattened ovals in shape, and at top vertical elongated ovals, as the rings there suspend the wheel and the superincumbent load. The action of obstructions the wheel surmounts is to compress the rings, which, when the obstruction is surmounted, causes the tire rim to bound forward by the released compression of the rings. A hundred miles' drive on very muddy roads showed that the ever-alternating shapes of the rings kept them from holding mud, so that splashing is less than with ordinary tires.

These wheels seem destined to develop new aspects of coach-making, as they and the superstructure may be so much lighter in wood- and iron-work, and the springs may be lighter for heavier loads.

Already a new cab company, with hansoms two-hundredweight lighter, with room for three riders on the seat, is being formed. This will be an immense advance in economy for cab-owners in the wear of their horses and harness, and allow cabmen to do quicker work with less fatigue to their horses or themselves; for it must not be supposed that cab-driving is free from fatigue to the men, even in the best weather for such work.

The only difference in this wheel to ordinary wheels in its make is the double tires, with the rubber rings riveted between them.

The spoke-tire is of T-shaped iron, the stem of the T being notched into the spokes and riveted there. To this spoke-tire is clipped the rubber rings of suitable strength for a 4 cwt. dog-cart, which will eventually be ½ cwt. less. A twelve-spoke wheel has thirty-six rings. The outer or wearing tire is of C iron, the rubber being clipped to the outer side of the C. The hollow is filled with a hard, light, durable composition.



**Patent Rubber Felloe Wheel.**

These tires are 1 in. wide on the sole, and about ⅞ in. deep in the channel. When the wheel revolves rapidly the rings are not visible.

They may be placed sideways or end on. The above is an illustration of the wheel.

## A RUSTIC FLOWER-HOLDER FOR TABLE DECORATION.

BY OMADAUN.

Its Form—A Gipsy Tripod—Natural Sticks to be used—A Cocoanut Shell for Flower-holder.

So very rustic is it, indeed, that it is almost with an apology that I present it to my fellow-readers; yet in its extreme simplicity there is somewhat of a charm, which I need hardly say is greatly enhanced if taste is displayed in the arrangement of the flowers; and having recently made one for my own dining-table, which has called forth great admiration, I am tempted to hope that a description of it may prove acceptable to others.

I can hardly claim for it any novelty of form, which, it will be seen, is simply that of a gipsy tripod, and the novelty—if it can be so called—lies rather in the simplicity of the materials used in its construction.

The tripod is formed with six rustic sticks, put together in the form shown in Fig. 1, and being tied with a sort of dried grass, known to all gardeners, I believe, as "bass." There is no attempt made at what I may call "finish," but the sticks must be firmly

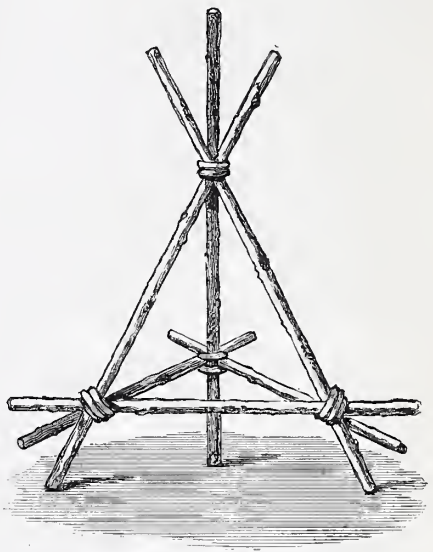


**Fig. 1.—Construction of Tripod.**

tied together at the joints, and the ends of the bass can be left either hanging loose or tied in a bow. The holder for the flowers is a cocoanut shell, which has been sawn in two, so as to leave one part a sort of cup or egg shape; three holes are drilled at equal distances round the edge (this can be done with a bradawl), and it is suspended from the tripod with three more pieces of the bass, which completes the arrangement. Of course, any small receptacle can be used in place of the cocoanut shell, but that,

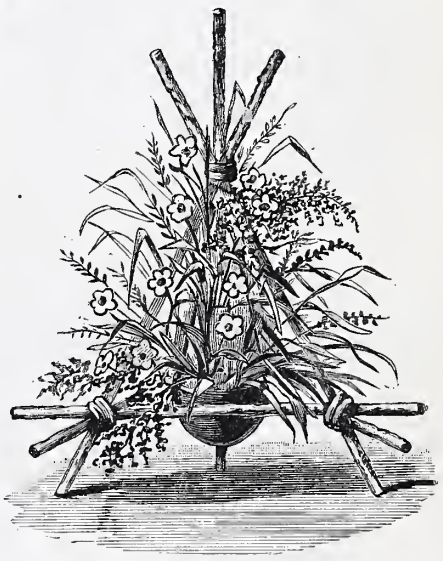

**Fig. 2.—Flower-holder Complete, with Cocoanut Vase in Position.**

perhaps, carries out its rustic appearance the best, and is very easily obtained.

In Fig. 2 I have attempted to show the tripod when decorated. The effect can be hardly more than "suggested" in a black and white drawing, but I can assure my readers that it is well worth the little time and labour necessary for its construction, which is of so simple a nature that no one need despair of making a satisfactory "job" in putting one together.

## A SIMPLE AND EFFECTIVE DRAUGHT EXCLUDER FOR DOORS.

BY H. HINGE.

INTRODUCTION, MAKING AND FIXING, ETC.

ALL house doors are so fitted as to admit being opened without rubbing on the floor, and it often happens that a little more has to be planed off to allow them to pass freely over a carpet or linoleum. Such being the case, we may expect the door, when closed, to have a space under, through which the air comes freely. In the summer months this is all right, and helps to ventilate the rooms; but in winter-time it is another thing altogether. Most of us have experienced the fact when in a nicely heated room, and, upon the door being closed to make the room more comfortable, we have still been chilled about the feet and

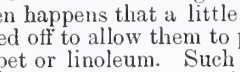

Fig. 1.—Transverse Section of Oak Strip.

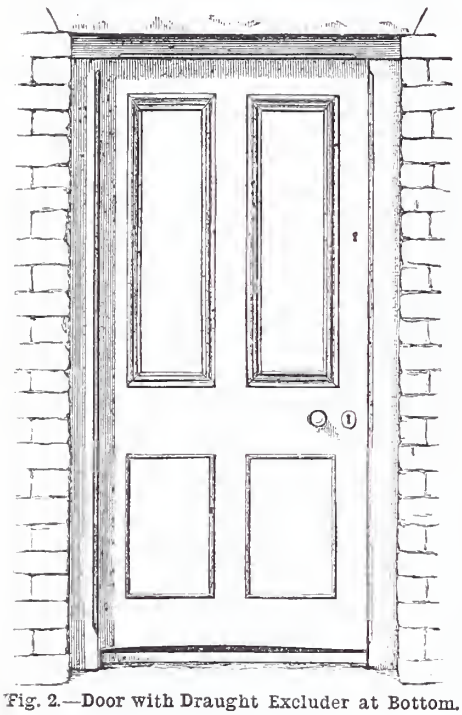

Fig. 2.—Door with Draught Excluder at Bottom.

legs. The cause of this is the draught coming through the space between the door and floor. A simple experiment will at once make this apparent to all. If a match or taper is lighted and held at the bottom of the door, the force of air will, in many cases, extinguish the light. This can easily be obviated by making draught excluders, and fixing them to our doors. The whole operation is so simple and the requirements so small that almost anyone who possesses a taste for mechanics can make and fix them.

*Making and Fixing.*—Procure a piece of oak, $\frac{1}{2}$ in. or $\frac{5}{8}$ in. thick, $2\frac{1}{2}$ in. broad, the length to be determined by the width of the door-casing (or frame). This must be rounded up till the end appears like Fig. 1, feathering it off on the edges to nothing, and rising gradually to the whole thickness. This should fit in tight (in the length) between the door-casing (or posts), the door closed, and the strip of oak gently tapped up into its place under the door till its edge just fills up the space between the door and floor. The door should now be opened, and a piece of felt or cloth, about $1\frac{1}{2}$ in. wide, tacked along the bottom edge of the door, allowing it to hang below the door about $\frac{1}{4}$ in. Now close the door, and, if it is in its right position, it will pinch up tight against the oak, and be perfectly air-tight. The strip of oak should be stained or painted to match the floor, and screwed down with three fine screws. It can then easily be taken up in warm weather. If it is a stone floor or step, holes must be drilled in it with a small iron chisel, and plugs of wood put in to receive the screws. Fig. 2 shows a draught excluder in position.

## OUR GUIDE TO GOOD THINGS.

**** Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

74.—ELECTRICAL NOVELTIES, ELECTRIC JEWELLERY, ETC.

MESSRS. CATHCART, PETO, & RADFORD, electrical engineers, send for inspection eight useful illustrated sheets of novelties in electrical instruments and appliances. This firm has been well known for several years as the makers of pocket batteries and accumulators, made of ebonite, and fitted with lithanode plates. These batteries have been much used for supplying current to small electric lamps on the stage and elsewhere in situations where portable electric lights are desired. In the repair of powder magazines, gas retorts, and steam boilers, these portable electric lamps are a boon. Body belts, to contain curved ebonite cells, are worn by the workmen, who can then freely move about with the electric light in their hats. These belts are sold at the low price of 7s. 6d. each. The firm also supply portable table electric lights and bull's-eye electric lights, from 15s. to six guineas complete. They also make a speciality of electric jewellery, made up in the form of pretty scarf pins and hair ornaments in silver and tortoiseshell set with brilliants, at prices varying from 9s. to 25s.

75.—SHEETS OF FURNITURE DESIGNS.

Messrs. Henry Zilles & Co. have just published some thirty or forty sheets of furniture designs for the use of art workers in wood. For information respecting prices, etc., and a list of subjects included in the sheets already published, our readers must be referred to the publishers, whose address will be found in the advertising pages of WORK. The drawings are boldly done, and treated in a broad and vigorous manner, but the designs themselves, however well calculated they may be to suit continental tastes, are too elaborate in ornamentation to meet the requirements and desire of English makers and buyers of furniture. The designs comprise a large variety of articles of furniture, from the grandfather's clock to the massive sideboard and drawing-room buffet.

76.—NONPAREIL ENAMEL LETTERS.

Mr. James E. Brindley has submitted to me specimens of his Nonpareil enamel letters, figures, trade marks, etc., for fixing to windows, showcases, glass door fanlights, and for fascias, signs, door-plates, and general advertising purposes. The letters and ornamental adjuncts—in the form of rules, corner-pieces, borderings, etc.—appear to be very much like opaque glass, cemented on to plates of clear glass. The method—although it does not apparently possess the merit of being perfectly original—of thus making, at a short notice, very attractive advertising tablets is simple enough. The following exhibits the nature and formation of the cement and the method of fastening the letters on the glass. The cement itself is made of white lead, with a small proportion of plaster of Paris and a few drops of gold size, mixed well together. It is applied to the back of the letter or ornament to be fixed on the glass with a knife, and the letter, etc., must then be pressed firmly in its place. The glass should be perfectly dry and clean before any attempt is made to put on the letters. All superfluous cement that appears round the edge of the letter after pressure must be removed with a piece of wood cut to a point, and the whole must finally be cleaned with dry plaster of Paris rubbed on with a brush. Mr. Brindley claims to make elegant and correctly shaped letters in a great variety of size and form at a low price; but for prices and particulars readers of WORK must apply to the maker, who will readily furnish these on receipt of a stamped envelope. Mr. Brindley is also making a speciality of window name-plates, and speaks of photos of this and another class of article that he manufactures, believing that there are numbers of people who would like what he terms a chaste and attractive display of their name and business from the windows of the ordinary dwelling-house. The other class of article to which reference is made is manufactured for cabinets, carriages, perambulators, cycles, etc. He also supplies alphabets for pigeon-holes, and labels for music drawers—such as "Piano," "Sacred," "Dance," etc.—which have been mentioned before now in WORK as necessary for the proper completion of musical and literary cabinet work.

77.—CLASSES FOR WOOD CARVING.

I am requested to call attention in "Our Guide to Good Things"—and in doing this I have considerable pleasure—to the fact that "The Worshipful Company of Carpenters, in conjunction with the Council of King's College, have established at that college wood-carving classes. The day classes are held on Monday, Wednesday, and Friday afternoons from two till five, and the evening classes on Mondays and Wednesdays from seven till nine. Arrangements have been made by which ladies are permitted to attend, and prizes are offered by the Company. Particulars may be obtained from the Carpenters' Company, London Wall, or of the Secretary at King's College." In thus seeking to give an impetus to the acquirement of wood carving, one of the most attractive of all the various branches of wood-working, the Carpenters' Company are doing their best to carry out a work that especially belongs to them, and in associating themselves with King's College in the task, they are moving in the right direction, for there must be many among the senior and junior pupils there who will be led to take advantage of the classes, and so engage in an occupation which will be a relief to their more serious studies, and perhaps lead up to a further acquaintance with wood-working, which cannot fail to be of utility to them in after life. THE EDITOR.

## SUGGESTIONS FOR WORKERS AND HINTS TO INVENTORS.

A SUBSTITUTE FOR PLATINUM.—Amongst the things really "wanted" by the manufacturing world is a substitute for platinum, which at present is found to be the only metal which will furnish wire suitable for connecting the carbons of electric lamps to the current wires. Unlike all other known metals, it contracts or expands under the influence of heat in exactly the same ratio as glass, and can, therefore, be embedded in the bulb necks without danger. It is quite possible that some of the Japanese metal alloys, which are trade secrets in the far East, may possess similar properties; and the matter is, at least, worth inquiry.

## SHOP:

A Corner for Those who Want to Talk It.

*** *In consequence of the great pressure upon the "Shop" columns of* Work, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—Letters from Correspondents.

**The Copus-Booth "Ideal" Patent Castor.**—I must ask the attention of readers of Work for a few moments to the illustrations of the mode of fixing these castors on round tables and single chairs as shown in my notice of this decidedly "good thing" in page 410 of the current volume, in which some of the blocks—the small blocks, I should say—illustrative of the castors, and the way in which they should be applied, have become misplaced. I presume it is owing to a misapprehension on the part of the printer to a certain extent, but mostly to the fact that the cuts were not whole and entire as one would naturally suppose them to be, but were made up by placing the small blocks inside the space defined by the circle in Fig. 2 and the trapezium showing single chair in Fig. 3. The difference between the right and the wrong

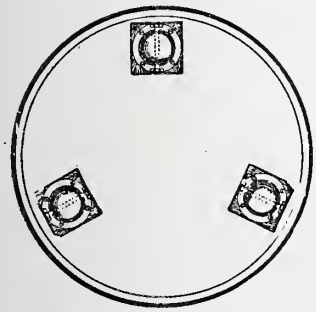

**Fig. 2.—Mode of fixing Castors on Round Table.**

method in putting on "Ideal" Patent Castors will be noted on comparing the illustrations in p. 410, which are wrong, with those given here, which are right. With regard to fixing castors on a round table, it is essential that the axes of the castor should, as I said, "point to a vertical line dropped from the

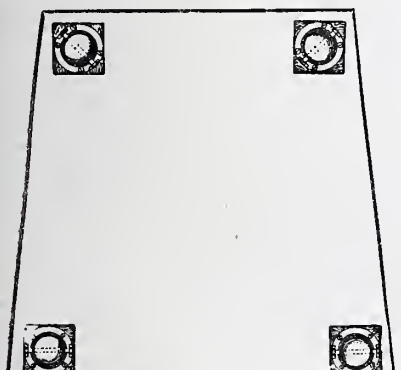

**Fig. 3.—Mode of fixing Castors on Single Chairs.**

centre of the table." In Fig. 3 "the axes of the front castors are parallel to the edge of the front of the chair, and the axes of those behind are at an angle of 45°, or thereabouts, with it." For the proper way under all circumstances, and for various kinds of furniture, recourse must be had to Mr. Copus's prospectus and price list.—Ed.

**Lamp Explosions.**—H. G. N. (*Islington*) writes:—"I observe in notes as to wants in Inventors' columns in Work that hitherto there has been no safety paraffin lamp invented. I am inclined to think that if lamps were made in the same way as the paraffin stoves—that is, with an extra stopper with a small hole in it for the gas generated by heat to escape—there would be no explosions, for I have never heard of a stove exploding. I have pointed this out to several lamp makers, but no one has adopted it yet, and I have too many irons in the fire to patent the idea myself."

**Cricket Bat.**—W. S. (*Northampton*) writes:—"Will you please put this in Work? as I think it very important that a misleading answer to any person or subject should, if possible, be put right. The answer about which I am writing appeared in p. 75 of the present volume, under the heading of 'Cricket Bat.'—No Name. J. W. H. says: 'Celebrated makers use pieces of whalebone halfway up the handle, and one-third down the bat.' Let me say that whalebone is not finished off halfway up the handle, but goes right through the same. Again, he says: 'Some make handles of lancewood and some of willow.' Has he lost faith in cane, or is it too much trouble to make it up into handles? He may introduce any article he likes into handles; but there is nothing yet to stand the wear and tear as cane. It holds into the splice better, and is so much lighter and stronger, and has more spring in it than anything, and resists, if made right, the jarring more than anything yet introduced. When makers line up handles with willow or ash, or any other wood, it is simply to reduce cost of material. Now with respect to the splice. Has J. W. H. ever made a spliced handle bat? I say no; and unless he knows what he is talking about, I think it would have been best to have left it alone; and if he has got an idea of his own, he can tell it to the nation, but do tell the questioner right. Now, the splice of a bat is not made as J. W. H. says, as a V-joint, but simply as a wedge, cut and fitted properly. I will defy him or anyone else to make a job of a handle splice made in the manner he has shown. He may make a clear joint back and front, and he may allow the glue to fill up the rest of the joints in the V. It is no good, again, as it has more tendency in it to split the blade than the plain wedge. Again, he says: 'The inquirer does not like pins or dowels;' but he strongly recommends them. *Let him!* It clearly proves he has no faith in his recommended splice. The inquirer is right; do not pin on any account. It is useless; and if made right, does not require anything but good joints and glue. If the querist cares to ask me how to make a cricket bat, if he will send me a stamped address, I will with pleasure tell him, as plainly as it is possible to do so, and tell him right."—[Any instructions you may wish to give must be given through the medium of "Shop," and not by private correspondence.—Ed.]

**Testing Accuracy of Framework.**—J. S. (*London, N.*) writes:—"I must protest against J. C. K. in his comments, page 427, terming as an 'erroneous plan' the method of testing the accuracy of framework which I and another contributor gave in different numbers. I should not have sent the hint had I not passed by the one previously given. I thought, however, that it might be useful to those who do not possess squares, compasses, etc., and not particularly for wood-workers. J. C. K. is, of course, right in his other remarks—at least, I cannot answer for the Egyptians, as I never knew them: intelligent, it seems, although no Work existed. J. C. K. supposes one side of his 'square' to be 5 in., and the remainder individually $4\frac{7}{8}$ in. long. Now, the amateur or professional workman who would cut four rails, each of which should be $4\frac{7}{8}$ in., and yet cut one much longer, is yet to be found. I will not believe such a flagrant error possible. But where four rails are *exactly* equal, or where a frame contains one pair of one length and another pair somewhat shorter, it is, by a long way, no impossibility that those rails *may* be mitred up apparently correct, and yet be out of the square. Naturally, I supposed it would be fully understood that outside measurements would be taken in addition to diagonal ones; which outside measurements, although proving the correct length and width of a job, would *not* prove its right angularity. It seems that if I do not stick to originality and designing, I shall get into hot water; but, happily, I have crawled out this time."

### II.—Questions Answered by Editor and Staff.

**Softening and Mounting Tiger Skin.**—Tiger.—Without being able to see what the present state of the skin may be, it is hard to give exact directions as to your method of procedure. If it has only been roughly taken off and cured, I should say damp it by rolling in damp cloths; stretch it tightly, hair downwards, carefully remove any lumps of fat, flesh, etc., with a knife, and then rub it down with pumice-stone and powdered chalk. The chalk takes out the dirt, grease, etc. A skin may be softened by rubbing only. The softness so much admired in certain skins brought from South Africa is said to be produced solely by long and patient rubbing between the hands of native women. But such substances as yolk of egg, oil, etc., worked into the pores, assist in giving pliancy. The kid skins of which gloves are made is softened with yolk of egg, and then rubbed backwards and forwards over the edge of a blunt semi-circular knife. As regards mounting, no lady who is clever with scissors and needle need find much difficulty. A thin crimson cloth, cut in scollops with the scissors, is generally used to surround the skin. For lining, a less showy material suffices.—M. M.

**Electrotyping.**—G. D. (*Lewisham*).—Assuming that the work to be copied is small, you will find the single cell process the most suitable for your purpose. Into a glass or earthenware vessel of about a gallon capacity place a white, close-grained porous cell, of about 3 in. diameter, and just a trifle taller than the outer stoneware jar. Next place an amalgamated zinc rod or cylinder, with a binding screw attached, in the inner porous cell, and then charge the latter with water, slightly acidulated with sulphuric acid. The zinc must not be allowed to touch the sides of the porous cell, but should be suspended in the solution by means of a couple of pieces of copper wire passed through holes drilled crosswise at the top of the zinc. For the outer cell make a saturated solution of sulphate of copper, by dissolving the pure crystals in warm water until it refuses to dissolve any more, and as soon as it has become cool pour the solution into the outer cell and add ½ oz. of sulphuric acid to each quart of liquid. A piece of perforated copper, cut to a suitable form, should now be suspended at the upper part of the outer cell, on which to support fresh crystals of sulphate of copper to compensate for the copper deposited on the mould, and thus keep the solution at a uniform strength. If preferred, a muslin bag filled with the crystals may be suspended in the solution for the same purpose. The plaster mould is now attached to the end of a piece of stout copper wire by twisting the latter securely round it, after which the entire surface to be copied is carefully and thoroughly covered with the best plumbago (blacklead). Thus prepared, the free end of the conducting wire is bent at right angles in the form of an L, and the short end is inserted in the hole in the binding screw of the zinc, with the other end of the wire to which the mould is attached dipping into the copper solution with its face *towards* the porous cell. A bright red deposit of copper will soon appear on the end of the conducting wire, from which it gradually spreads over the entire surface of the mould. If the copper deposited on the mould appears to be dark, the latter should be moved further away from the porous cell, as it is a sure indication of the current being too strong. When the current is weak it gives a pale or crystalline deposit, which should be corrected by bringing the mould nearer to the porous cell, or by the addition of a few drops more sulphuric acid in the inner cell. Whenever it becomes needful to alter the position of the wire attached to the mould, it is important to always screw up the nut of the binding screw tight again. In an ordinary way an electrotype sufficiently stout for all general purposes can be obtained in about twenty-four hours; but the action can be continued much longer if desired. Care should be taken not to remove the mould too soon, otherwise the electrotype may be accidentally damaged. If both sides of the mould have to be deposited upon, it will be requisite to occasionally turn the mould in order to secure a uniform deposit, as the copper always forms the thickest at those parts of the mould which are nearest to the porous cell. The mould can generally be separated from the electrotype by plunging them in hot water for a few minutes, after which the metal is trimmed up, polished, or lacquered, according to taste. Should any difficulty occur, write again as fully as possible. By looking up the Indexes you will find that several answers have already appeared in "Shop." You might, with advantage, read the articles which appeared in *Amateur Work*, Nos. 72, 73, 74, and 76, published at 6d. each by Messrs. Ward, Lock, and Co., Salisbury Square, E.C. Coin enamelling is too difficult a branch of work for an amateur to attempt with any hope of success, as the coins require to be undercut, then floated with the enamel, and afterwards fired and polished, the colour and beauty of the designs being mainly dependent upon the manner in which the engraving is executed. There are very few really good enamellers in the trade.—C. A. P.

**Geometry: Honours.**—J. W. C. (*Tavistock*).—Good books to use in reading for honours are: "Euclid," Hall & Knight; "Conic Sections," Smith. Write to Cassell & Co. for their catalogue of school works.

**Lamp.**—J. T. (*Biggleswade*).—I am not aware of a lamp being in the market for boiling water which burns benzoline. There is one which is used by plumbers, which forms a blowpipe lamp, using benzoline; but an ordinary methylated spirit lamp would be much more suitable, and three tablespoonfuls would certainly suffice to boil a pint of water in three minutes.—C. M. W.

**Aquarium.** — G. A. G. — As your aquarium measures 18 in. by 9 in., and is, I presume, of a proportionate depth, it is too small to admit of an effective self-acting fountain being inserted in it. You should have provided for the fountain before making the aquarium. You can, however, get over the difficulty by making a stand for the aquarium upon the lines of a fountain fully described in No. 69 of Work, and connecting the jet-pipe, screw-plug, and the main pipe to the inside of your aquarium at similar points to those which they occupy in the diagram, covering them with rock-work. The only difference in practice will be that your aquarium will form the top basin instead of the open one shown in the diagram. Make the tanks to any dimensions you like.—C. M. W.

**Fountain.**—Fountain.—Your sketch of fountain has not reached me. You say that you made a fountain, but failed to make it play more than three-quarters of an hour. I should consider that a very fair time. Should you desire to make it play longer, you have only to make the vessels larger. With reference to furnishing you with a design for a combination fountain and fern-case, I shall be happy to do so upon learning some particulars as to size, material, and the position it is intended to occupy; also whether a plain or an elaborate design is wanted.—C. M. W.

**Saw Blade.**—CYMRO could get a piece of band saw from the following agents and makers, which would suit his purpose by punching a hole in each end: C. D. Monninger, 10 and 11, Ray Street, London, E.C.; Messrs. Eadon, President Works, Sheffield; Messrs. Aublet, 35, Curtain Road, London, E.C.; or from almost any saw-maker. The price of saw, ⅜ in. wide, would be 2½d. per foot; ½ in., 3d. per foot. You do not state the kind of handles you want to fasten. I should say to fasten with a good rivet would be the proper way to fasten them firmly.—A. R.

**"Work" Exhibition.**—R. O. (*Elgin*).—No "Work" Exhibition will be held for 1891-92.

**Standing Hammock.**—F. H. B. (*Forest Gate*).—What do you mean by a "standing hammock?" Hammocks are always slung, and must be so from their construction. There is an article entitled "How to Net a Garden Hammock" in Vol. II., p. 425, otherwise No. 79. It is impossible to answer any question in the number that appears in the week following its reception.

**Flower Stand.**—F. H. B. (*Forest Gate*).—Buy the Indexes to Vols. I. and II. of WORK, and you will then, by searching them, be aware of all that has been done in this direction, and be able to indicate to the publishers what articles you require. The Indexes may be obtained through any bookseller or newsagent, and the cost no more than 1d. each.

**Carpenter's Shop.**—F. H. B. (*Forest Gate*).—Your application is devoid of any particulars that would enable anyone to answer it. How could anyone tell you "how to fit up a carpenter's place, where to put the tools and shelves, etc.," when all the information you vouchsafe with regard to the place is: "The shop is oblong shape—I mean the place I work in." Send a plan, with dimensions, etc., and showing where the door and windows are. Writers can no more give practical directions that would be of any real value to you than the Israelites could make bricks in Egypt without straw.

**Cost of Patents.**—YOUNG CHIPS.—Under the provisions of the New Patent Act of 1883, the Government fees or stamps on applying for the grant of a Patent for an invention is a stamp impressed—of £1—on the application form, in reply to which, if accepted, the provisional protection is granted, which lasts nine months, at or before the end of which term a complete specification, drawings, etc., must be filed, and this specification has to bear *three* impressed stamps of £1 each; and when the documents are accepted, the Patent issues. These stamps, however, have nothing to do with the cost of preparing the documents, drawings, etc., required by the law prior to the grant of the Patent, which will vary according to the amount of work required to be done, and the skill, ability, and experience employed in the performance. This kind of work cannot be successfully carried out by ignorant and inexperienced inventors, unaided by proper skill and knowledge of Patent matters, and it is owing to the persistent attempts of such people in preparing and putting in their own documents that the Patent Office records are being filled with invalid and useless Patents, hundreds having been patented long before, and others most hopeless and useless crudities; which is causing Patents to be regarded with suspicion and contempt, and doing an injury to Patent property which it will take years to put right. If a thing is worth doing at all, it is surely worth doing well.—C. E.

**Patenting.**—S. F. D. (*Lewisham*).—There is nothing to prevent an inventor preparing and putting in his own documents and making application himself personally for the grant of a Patent, if he pleases to do so. Before, however, he attempts to do this, he should ask himself if he understands what a Patent is, what it is required to comprise, and what he knows about Patent Law and the judicial requirements for a sound and valid Patent. If he arrive at the conclusion that he does not know, and has had no experience in such matters—as in ninety-nine cases out of a hundred it will be found is the case—it seems to us that he should decide that it would be a very foolish proceeding on his part to attempt to meddle with matters of which he possesses no knowledge or experience, and that, therefore, he should at once place himself in the hands of a respectable, skilled, and experienced person, capable of carrying out his wishes in a proper manner, or he will quickly find he is adding another useless and invalid Patent to the already existing mass of such as are on record. Unless one knows exactly what work has to be done in preparing the documents, drawings, etc., for his invention, and ascertaining the novelty of it, it is impossible to name an exact price for the cost, the work and requirements varying so much in each case.—C. E.

**Leaking Cocks.**—W. S. (*Ilford*).—Our correspondent does not tell us what kind of packed cocks he has to do with—whether shell-packed, plug-packed, or screw-down washer; but, according to his statement, they have begun to leak very soon. If I knew what kind, or whose Patent, they are, I might be able to give him the required information.—C. E.

**Ploughs.**—H. U. (*Ballycanew*).—These can be bought in several places, but Mr. McKinnon, Carrick Street, Glasgow, has long been known for producing excellent articles at a reasonable price. I would advise you to write to him. George Royle, Lovell's Court, Paternoster Row, London, also supplies them.—G. C.

**Telephone.**—T. R. M. (*Liverpool*).—The information you ask for is too much for "Shop" columns. It has already been given piecemeal through various numbers. Look up the Indexes, which you should have by you. Judging from the number of letters I have had from you, you are a constant subscriber, or, at least, should be. We never answer by post; so you must wait if you want information through "Shop," as others are content to do.—W. D.

**Selling a Patent.**—W. J. (*Heaton, Newcastle-on-Tyne*).—An invention for which provisional protection only has been obtained is *not* a Patent, and cannot be sold as such, there being no property to sell until the Patent is sealed. A man may sell his invention under these circumstances, covenanting to complete and assign the Patent when granted, if he can get parties to agree to such an arrangement. We have often carried out business of this kind; but, as a rule, it is not generally done, nor is it advisable to make such arrangements. It may, in some cases, be both advisable and advantageous to both parties to do so, but this will depend on circumstances. By law, a Patent is only granted to the true and first inventor; therefore, in strict law, any person whose name is added to that of the inventor, but who has not invented anything in the matter, will at once invalidate the Patent! What is the object to be gained by doing what our correspondent seems to wish, judging from the nature of his query? The proper thing to be done in the case is for the real inventor to apply in his own name for the grant of a Patent for his invention, and when obtained, he can then sell and assign his rights as he seems to desire, or make any other suitable or desired arrangement, there being then a property to be dealt with.—C. E.

**Bookbinding.**—AMATEUR.—I am pleased that you have been able to bind books from the instructions given in WORK. I am astonished that you want to know what a press-pin is, particularly so, seeing that you say you have a press, etc. A press-pin is simply an iron rod about the length of an ordinary kitchen poker, for putting into the holes at the ends of the screws, and is used as a lever for tightening up the press. A description of the process of making one is superfluous. If you have not one, you could use the poker with advantage. Pressing boards are smooth wooden boards for putting between books while in the press. Backing boards are long, narrow strips of hard wood with the top edge bevelled, and are put along the back of the book during the operation of backing. These things are fully explained in the articles on this subject. Rolls, fillets, and pallets are finishers' tools made of brass, with a pattern cut upon the face of them, and are used for the ornamental work. Read the articles over again, and you will get full particulars of all these. Your lathe and carpenters' tools will be of little use in the manufacture of these articles.—G. C.

**Oil Paper.**—C. B. P. (*Rockferry*).—You want to know how to make oiled "royal," "black carbonic," and "manifold" for duplicate order books, so that you will be able to manufacture them. In the first place, you will require elaborate machinery; and secondly, you would require to have a paper mill in full swing, as the first two papers are made from waste outsides and sheets with some flaw which would prevent them being sold as perfect ones. The tissue is prepared during manufacture; so you would have to set up a paper-maker's plant for this alone. I cannot give instructions for setting up a paper-maker's plant—at least, in this column. I know something about this class of machinery, and if you are really going in for it, I could advise; but if I was doing it here it would be somewhat of a free advertisement, which I would rather avoid.—G. C.

**Electric Bell Magnet.**—T. B. (*Liverpool*).—The number of layers of wire to be laid on the bobbins of an electric bell magnet are determined by the battery power to be used in ringing the bell. If a low-tension current of full volume is to be used, a few layers—say two or three—of coarse wire will be required. If a high-tension current of thin volume is to be employed, the bobbins must be wound with several layers of fine wire. In No. 12, Vol. I., of WORK, on p. 180, you will find a full table of the proportionate parts of electric bell magnets. For a 3 in. bell, the bobbins should be 2 in. in length by ¾ in. in diameter, and filled with No. 24 silk-covered copper wire. For a 4 in. bell, the bobbins should be 2½ in. by 1¼ in., and filled with No. 22 wire. For a 6 in. bell, the bobbins should be 3½ in. by 1⅝ in., and filled with either No. 22, 18, or 16 wire, just as may be required to balance the battery power. A greater number of turns or layers will ensure a stronger magnetic pull and a stronger stroke, if the tension of the current is high enough to overcome the extra resistance of the additional turns. A bobbin will take more layers of a fine than of a coarse wire, and the resistance will also be higher.—G. E. B.

**Leyden Jar.**—T. F. (*London, W.*).—Get a wide-mouthed glass jar holding from one to two pints, or a confectionery glass jar. Also get some good tinfoil and some thin varnish. Rinse the jar with some thin varnish, then coat it with tinfoil to within about 1 in. of the top. Coat the outside in a similar manner. Get a disc of hard wood (such as mahogany) to fit the mouth of the jar, and have it smoothly polished and varnished. In the centre of this disc fix a brass rod 4 in. in length, with a hook turned on the inside end, and a round brass knob on the outside end. Hang a piece of brass chain to the hook inside, and let the chain be long enough to just touch the bottom of the jar. The brass rod may go to the bottom of the jar and terminate in a disc of wood coated with tinfoil, instead of having a length of brass chain, if so desired. The upper part of the rod above the cover may be curved, but must terminate in a metal ball. To charge the jar from a Rhumkorff coil, place the jar on a thick piece of glass, on which has been placed a sheet of tinfoil. Connect the tinfoil with one terminal of the secoudary wire, and connect the knob of the jar to the discharger. Work the coil in the usual manner, passing sparks between the points of the discharger; but do not allow these to touch each other.—G. E. B.

**Electric Engine.**—J. M. (*Liverpool*).—Electric engines made in imitation of steam engines rarely work in a satisfactory manner. If you wish to work your model lift with a small engine made in imitation of a steam engine, but driven by electricity, do so in the following manner: Make or get a model steam engine. Also make or get a small electro-motor, and conceal it under or at the back of your model lift. From the motor convey a fine gut band to the driving-shaft of the engine, and work the engine with this. A model electro-motor suitable to this purpose was described in No. 109, p. 71, Vol. III., of WORK. The motor may be made to work the driving gear of your lift direct, if you do not wish to show the engine. The battery of three or four pint bichromate cells may be at some distance from the motor, the current being conveyed by No. 18 wire. The speed will be high, but you can pull this down by suitably reducing pulleys or wheels. The motor will pull the lift up, but it will fall by its own weight when the current is switched off, so should be provided with a brake to ease the descent.—G. E. B.

**Dry Battery.**—W. C. H. (*Godalming*).—The makers of dry batteries either patent them, and thus protect themselves against imitation, or keep the process and proportions a dead secret. On p. 97, Vol. II., of WORK, in reply to G. A. B. (*Ascot*), I have given instructions on making a dry battery; and in several other parts of Vols. I. and II. you will find information respecting the Gassner dry battery. This is all I can tell you about them. I cannot give you the "exact quantities of materials" used in dry batteries.—G. E. B.

**Materials for Coils.**—EXPECTANT.—Ebonite, platinum, and other material used in the construction of coils, can be obtained from any dealer in electrical instruments. Among those known to me are Messrs. King, Mendham & Co., Narrow Wine Street, Bristol; Mr. Bottone, Wallington, Surrey; Mr. G. Bowron, 93, Praed Street, London, W.; Messrs. Bonney & Co., 19, Avenue Road, Lewisham; and Messrs. F. C. Allsop & Co., 165, Queen Victoria Street, London, E.C. Sheet ebonite for coil ends and discs costs about 5s. a pound; platinum varies very much in price from week to week. By writing to one of the dealers mentioned above, you can always get a current quotation. If you want any odds and ends for coils, I should advise you to pay a visit to the electrical museum and second-hand emporium of Mr. A. Caplatzi, 3, Chenies Street, Tottenham Court Road. He has a great variety of coils and oddments of coils for sale or exchange.—G. E. B.

**Silver-plating Tricycle.**—B. B. (*Bradford*).—The simple silvering pastes you inquire about are useless for silver-plating the bright parts of a tricycle. Nitrate of silver will not deposit its metal by contact with bright steel, nor by simply immersing the steel in a nitrate of silver solution. All pastes containing silver are useless for plating steel. They can only be used in whitening bright and freshly cleaned surfaces of copper and of brass. To silver-plate bright steel, it must be first coated with copper or with brass in an alkaline coppering or brassing solution, and then silvered in a solution of double cyanide of silver and potassium. As these processes will involve the use of costly appliances and solutions, I should advise you to send your tricycle to a professional plater, or to the maker of the machine, and get it plated. The plant needed to properly plate tricycles will cost about £150 at the lowest estimate.—G. E. B.

**Battery for Electric Light.**—H. G. (*London, N.W.*).—The Bunsen is, without doubt, the best battery for electric-lighting purposes. It is not generally liked, because it gives off nasty poisonous fumes of nitrous oxide whilst at work; hence it has to be placed in an outhouse, and the wires brought to the lamps. It gives a strong and almost constant current for a period of from six to eight hours, if properly set up and used. At the end of each run of from six to eight hours it must be taken to pieces and cleaned, and its parts must always be put away clean. Get Nos. 1, 2, and 3 of WORK (obtainable from Messrs. Cassell & Co.), and read the articles therein published about the Bunsen battery. They will tell you all about this battery, and how to amalgamate the zincs. Your four cells must be connected in series—that is, in tandem: zinc of one cell to carbon of next cell, and so on, a wire from a zinc at one end, and another wire from the carbon at the other end of the battery forming the line wires to the lamp. The four cells, thus connected, will furnish enough current to light up a 6 volt 5 candle-power lamp. The battery might light two such lamps if the lamps were placed side by side.

If the lamp or lamps do not light when connected to the battery, the voltage of the lamp is too high, and more cells are required to overcome its resistance.—G. E. B.

**Small Horizontal Engine.**—C. F. (*Eastbourne*).—You ask advice as to making a small horizontal engine, and that is exactly what I am trying to give in WORK; I suppose, therefore, you have only just begun to take it in. Get Nos. 106, 110, 121, 125, and 131; the articles are also continued in the present number. You will see in No. 121 the size of the fly-wheel. The castings for this engine will shortly be advertised. You can buy second-hand engines by advertisement in the *Exchange and Mart*, or the *English Mechanic*, or at Caplatzi's, Chenies Street, Tottenham Court Road, London. The boiler may be 2 ft. 6 in. high and 1 ft. 3 in. diameter, and have a cross tube in the furnace. This will be a one-horse boiler.—F. A. M.

**Copal Varnish.**—F. T. (*Liverpool*).—To make copal varnish appears to be the height of many an amateur painter's ambition, judging by the queries for ingredients received. We have repeatedly stated that the novice has not the faintest chance of making it successfully. F. T. wants to know the *probable* cost of making a gallon. Here are a few items: the value of several domestic pots and pans, of the loss of his peace of mind, his wife's respect and patience, a quantity of good oil, turpentine, copal gum, etc., and perhaps the cost of putting out a fire right up the kitchen flue! Varnish is made according to the purpose it is intended to be used for. Prices range from 6s. to 36s. per gallon, and there is now so much competition amongst large manufacturers, that even were it a simple thing to undertake, copal varnish could not be made on the kitchen stove nearly so cheaply as it can be bought.—F. P.

**Litho Transfer Paper.**—W. G. (*Blackburn*).—Transfer paper is so commonly used now, and is so easily obtainable from any dealer in lithographic materials, that it is seldom, if ever, necessary for anyone to make it for themselves. By the way that you word your question, I do not quite understand whether you want a receipt for making the paper itself, or whether you wish to know the mode of proceeding to work in transferring from stone to stone, or from plate to stone, as the same paper may be used in either case; but I will give a couple of the most general receipts for making the transfer paper. Should the paper be required to be transferred to a warm stone, mix a size strong enough to be quite firm when cold, by boiling either parchment cuttings, glue, gelatine, or isinglass, etc. A good coating or medium to be used with this is either plaster of Paris, flake white, or chalk, etc., flake white being, perhaps, the best; this should be mixed smooth with water. Then warm the size, and pour the mixture into it, after which strain through a sieve or piece of muslin, but only experience will show how much white it is necessary to put to any certain quantity of size. A large flat camel's-hair brush should be used to put the coating on the paper, and any kind of paper may be used, such as ordinary drawing-paper, or very thin paper if the drawing to be transferred is very fine. Should the paper be required to be transferred to a cold stone, it is better to use starch in place of the size, and mix it with glue. The more adhesive the paper is required to be, the more common should be the kind of glue used. There are excellent papers for transferring good chalk work; but as these are more expensive, they are not so generally used as the following. The ordinary Scotch re-transfer paper is so well known that the receipt hardly bears repeating; but as every day brings fresh workers to the field of lithography, someone may be benefited if I herewith give it. It is simply made by mixing plaster of Paris and flour in equal proportions, by first mixing the plaster of Paris (which should be of the best) with water until it becomes a smooth liquid; this is obtained by continually adding a little water, and constantly stirring it, until it loses its natural propensity of settling into a hard substance. Then mix the flour with a little water, and boil it to a paste of ordinary consistency, after which add the paste to the plaster, well mix, and strain through a coarse muslin or fine sieve. Colour it by adding a little gamboge or vermilion, etc., which, when applied to the paper, enables the artist to easily distinguish the right side from the wrong. This applies equally well to the above receipts, and any kind of transfers can be taken from this paper, either from stone to stone or from plate to stone. Should you wish to know how to proceed in *transferring* from plate to stone, I shall be pleased, with the Editor's permission, to answer this, or any other question relating to artistic lithography, in "Shop."—A. J. A.

**Reverse Transferring for Lithography.**—T. A. J.—There are several methods of reverse transferring—to change the black letters of type, etc., to white ones on a black ground—one of which is to protect the drawing on the stone, or, in this case, the lettering, with resin, and etch it until the letters are raised from the level of the stone to a degree perceptible to the eye. Then wash the stone, first with turpentine to remove the ink, then with clean water, after which paint the stone solid all over with litho ink. When dry, it may be rolled up in the ordinary way in printing ink. The letters being now raised, it is necessary to level them to the stone with snake-stone; and the stone can be easily gummed, rolled up, and printed, the letters standing out white on a black ground. Should any accident occur to the groundwork in using the snake-stone, it can be easily filled in and remedied with litho ink. To make the letters level requires a very nice, neat, and patient piece of work. Another method is to take an impression of the subject in a strong ink, and dust powdered gum-arabic over it, so that it becomes slightly sticky if held before a fire or allowed to remain in any damp place. This now being placed over a damp stone, the gummy surface—and, consequently, the design or lettering—will be transferred to the stone. This should now be allowed to dry, and then the stone covered all over with litho or any greasy ink, and if the stone is washed in the ordinary way the lettering will stand out white on the stone, as the gum will protect the stone from the ink wherever the design comes. These are only two out of several methods for reverse transferring without the artist's assistance, several others being equally good; but I have only given the above so as not to confuse you in starting. It would be a good plan for you to try both and see which you prefer, but in either case you must be particularly careful to see that the edges of the letters are clean and neat. Should you, however, find any difficulty in working, write again, and let me know where your trouble lies.—A. J. A.

**Zinc Plates for Lithography.**—LITHO.—Zinc plates may be purchased ready grained for the lithographer's use at any of the dealers in lithographic materials. But, presuming you have only bought the plain zinc, and wish to prepare it yourself, as your question seems to imply, you would proceed in the following manner: After the zinc has been well rolled at the dealer's, it must be cut into sizes suitable to the subject in hand, and care will have to be taken to see that it is level and of equal thickness all over. Should the plate be required to be constantly in use—that is, as soon as one subject is finished the plate is required to be re-grained ready for another—it is advisable to choose one thicker than if the one subject is to be drawn and kept on the plate, to allow for the wear in preparation. The zinc never being quite free from oxide, dust, etc., when first bought, it is necessary that all such foreign substances should be scraped off with a sharp scraper, which should be used at an acute angle with the zinc, so as not to dig holes into it. The next process is to treat it like a litho stone by smoothing it with pumice-stone (*vide* p. 19, No. 106, Vol. III., of WORK). But where zinc differs from stone is, that *every kind* of work must be drawn on a grained surface, no matter how fine it may be. It is, therefore, necessary that the zinc should be grained; this gives it that dull, rough appearance that you mention and point out in your sample (No. 1). The zinc must be grained in exactly the same manner as stone, only using a zinc muller instead of a stone one. After the plate is finished and well rinsed with warm water, it should be dried quickly, to prevent the water corroding the zinc. The finest grain may be given to the plate for pen work, and, naturally, a coarser one will be required for chalk work. These are the general principles for preparing zinc plates for lithographic purposes; to enter more into detail would be to take up too much of the valuable space of "Shop." In specimen 2, the colour and surface are obtained by coating the zinc with a solution composed by grinding lithographic stone down to a fine powder, making it into a pulp with water, and then laying it on the zinc, which gives it a surface like stone, and which, it is needless to say, can be, therefore, either polished or grained, and may be used in the same manner as a litho stone. A firm in Leipzig hold the patent for this kind of plate with a litho stone coating. It would, therefore, be advisable to apply to them or their agents if you wish to obtain them.—A. J. A.

**Graining.**—J. T. R. B.—Vol. II. of WORK contains a complete and illustrated series of papers on the art of graining. Send for an Index, and then you will find particulars of each lesson. They form a thorough foundation for any learner, and are written for the instruction of those having no other means of getting lessons. Classes are held in graining at the Finsbury Technical College. The finest work on graining, with beautiful coloured reproductions of grained panels, is published by the proprietors of the *Journal of Decorative Art*, 15, St. Ann Street, Manchester.—LONDON DECORATOR.

**Enamel.**—CHARLES.—Why attempt to make enamel when so many reliable brands are on the market? A useful bright red can be made by dissolving sealing-wax in methylated spirit, but this is only fit for fancy goods not exposed to the weather. No ordinary mixture of pigment and varnish can be made to answer so well as Aspinall's, for instance. Let me advise you to get the back parts of WORK, and complete your volume. You will find it a great bargain.—F. P.

**Painting.**—E. H.—There is no work published dealing solely with the pricing and measurement of painters' and decorators' work; but any established builders' price-book contains a set of charges such as architects require. When you consider that wages vary as much as 25 per cent. between different parts of the country, and that the condition and required finish have more to do with the price of painting than the quantity alone, you will gather why such a book could not be compiled. *Mensuration* should be studied for learning *how* to take quantities.—LONDON DECORATOR.

**Lime Wash.**—G. M. G.—The cause of your liming turning yellow is probably due to the stained condition of the surface it is put upon, and which stains will strike through every coating. Try scraping off all the old coating with a wash of plaster of Paris and water, and then re-lime. Use chalk-lime; get it fresh from the kiln, and slack it when you intend to use it. A little blue or black colour helps to kill the yellow tint of the lime, but it will not affect the staining trouble.—F. P.

**Plumbago.**—H. P. (*Ash-next-Sandwich*).—Are you not aware that plumbago is the chemical name for blacklead—*oxide of carbon?* I fail to understand the purpose you require it for, and what you mean by small quantities. However, for 1 lb. I should say, go to the oilman; for 1 cwt., write to Farmiloe and Sons, Rochester Row, London, who will quote you for any such commodities according to your requirements.—F. P.

**Waterproof Covers.**—SCOT.—WORK, No. 73, page 340, contains a reply on "Waterproofing Canvas," which appears to be the receipt you want. If you have not that issue, send 1½d. to the publishers, and they will forward same at once.—F. P.

**Oak Graining.**—J. S. (*Birmingham*).—The only patterns for practice work that I can personally recommend to the student are those published with the Manchester work on graining. These are some of the best English chromo-lithography work that has been produced; and as the original panels were executed for the book by past-masters in the art, nothing finer can be desired. Write to 15, St. Ann Street, Manchester, and mention WORK. Inquire also, from the same source, as to panels of real woods for learners.—LONDON DECORATOR.

**Paint and Distemper.**—M. N. (*Rockhampton*) wants to know what will prevent the salts of cements coming through paint and distemper. You should not have painted the wall just after it had been made good, as it had no time to dry, and, as you may naturally expect, when you rub a wet article over a wet article the latter gets diluted with the former, as it has done in your case. The wall should have been left to dry for about a week at least, and then well sized before being painted. You ask me, in your letter, if I can give you a remedy for Portland cement. If you will repeat your question more clearly, and tell me what is wrong with your Portland cement, I will only be too pleased to try and answer your query.—W. B.

**Exposure for Enlargements.**—G. F. G. (*Oldham*).—Having made the enlarging camera, I take it for granted from your letter that you are familiar with the process of developing, and simply desire a few hints about the exposure necessary. This varies very much, according to the density of the negative, the time of day, the intensity of the light, and several other factors; and experience alone can guide you in the matter. I give you a few notes from a book in which I register particulars of all my exposures. They may serve to give you an idea as to how to proceed. January 6: thin negative, stop f 10, foggy day; exposure, 35 minutes; Eastman paper. February 10: ordinary negative, stop f 10, dull day; Eastman paper, 15 minutes. July 12: ordinary negative, stop f 20, bright day; 6 minutes. October 4: dense negative, stop f 20, sunny day; Ilford rapid paper, 2½ minutes. You will thus see that the necessary time varies considerably. A good plan is to proceed as follows: Take an ordinary negative, put it in the camera, cut a strip off your paper ½ in. wide, and place it in the dark slide; pull out the shutter one-fourth, expose five minutes, pull out another fourth, expose another five minutes, then again a fourth more for another five minutes. The strip will thus be exposed five, ten, fifteen, and twenty minutes in different parts; develop, and see which exposure is nearest perfect, then time your enlargement accordingly. Avoid letting the sun shine on your negative when enlarging. I generally choose a dull day, as I find the results, with long exposures, to be much more satisfactory. In the matter of papers tastes differ, but I think you will be quite satisfied with either Eastman's or Ilford rapid. I prefer the former, although a trifle dearer.—G. LE B.

**Plush for Frames.**—PLUSH FRAME.—An article on plush-covered frames is in the hands of the Editor, and if it has not appeared ere you see this, it will do so shortly.—D. D.

**Cabinet Maker.**—COUNTRY LAD.—I can quite appreciate your difficulty in acquiring practical experience in making good furniture. It is a most difficult matter to find a so-called cabinet-maker's shop in which the things are made for general sale. Wherever you go you will find that all the shops in which the furniture is sold to the public get the bulk of their goods from London, where it is made and supplied by wholesale dealers. The actual makers there seldom make more than one class of article, and though there are some shops in which really good things are made, they are comparatively few. If you could get into one of them, you might, by keeping your eyes open and working hard, learn a good deal; but undoubtedly your best plan would be to avoid the trade shops, and get into some retail house where things are actually made. Although, as I have said, most of the things are bought from outside makers, there are many retail cabinet makers who keep a few men for general work, and it is in such a shop that you will gain most experience. As such shops are found all over Great Britain, or, at any rate, in all the larger towns, such as London, Birmingham, Liverpool, and Manchester, you will see it is quite impossible to give you a list of firms who might be willing to engage you, even were I able, off-hand, to be able to sit down and write one. All you can do is to watch

your opportunity and make inquiries from your fellow-workmen; but I do not think you stand much chance of getting such employment as you want where you now are. I do not know if you have joined either of the cabinet-makers' trades unions. If you are able to, you might find it to your advantage to do so, though I fear, from what you say of yourself, that you would hardly be eligible. I am not at all surprised to hear that you have found the articles in WORK to which you allude of use to you. You will find more practical information in its pages than in any other periodical.—D. D.

**Plating Forks.**—W. G. (*Harrogate*).—For the price paid (30s. per dozen) the best quality could not be expected. Have they been carefully treated and cleaned with fine polishing powder, such as washed whiting? or have they been left in vinegar, etc.? Coarse polishing materials will soon fetch plating off, and so will vinegar and sauces. It will be best for you to take them to some respectable silversmith or jeweller in your town, and ask him to get you an estimate for re-plating with silver, which should cost from 15s. upwards the dozen to do properly. As the metal itself is yellow, it might be well to get an estimate to nickel-plate them first, and silver-plate them afterwards; or perhaps nickel-plating alone would do, when the cost would be 7s. 6d. upwards for the dozen. Nickel has not the colour of silver, as you can see by looking at the plated parts of eyelets. If you buy other plated goods and want the best, it should be that known as E.P.N.S., which can be translated, English plate nickel silver; but you will have to depend on your silversmith, anyhow, so choose a man of established reputation.—H. S. G.

**Black Varnish for Pins.**—J. W. (*Kensington*).—No special machinery is required for these, only a few cans with gauze bottoms, and a larger piece of gauze in a frame on which to spread the pins for draining and drying. The varnish used is what is generally called japan, and requires a stove heated at a temperature of from 250° to 300° Fah. These japans, of which asphaltum, gum amber, and boiled oil, form the chief ingredients, requiring from three to five hours' boiling, and a special knowledge and appliances to make satisfactory, are best bought ready made from the makers; in fact, large japanners seldom make their own. Should you, however, require the proper proportions and ingredients, and will write us again, we will gladly furnish them. As these japans are thinner when hot, it may be necessary to adopt some plan, such as a sand bath, to keep them hot when using; and as for the purpose you name a brush is useless, it will be seen that the better plan would be to put the pins in one of the gauze-bottom cans, place this over a water-tight one, and pour the japan through; drain well, and spread out on the gauze in the stove to dry. How much heat is really necessary, and how long an exposure is required, can only be acquired by actual experience. There are many makers of japans and varnishes in your neighbourhood to whom you might write, giving full particulars of your requirements: W. T. Bigsby, Trundley's Road, Deptford, London; R. P. Butteress & Co., Assembly Place, Mile End, E.; C. W. Schmidt, Carpenters' Road, Stratford, E.; Meredith and Co., 107 and 108, Lionel Street, Birmingham.—LIFEBOAT.

**Anti-vibrator.**—G. W. C.—The anti-vibrator described in WORK, page 407, Sept. 12th, No. 130, is not protected by any patent rights, and can be made and sold by anyone.—CYCLOPS.

**Anti-vibrator.**—CYCLIST will be able to get the castings for the anti-vibrator described in WORK, page 407, Sept. 12th, from H. Cliff, Old Foundry, Leeds Road, Bradford, by sending patterns of same; or he could, no doubt, get the anti-vibrator made complete by Mr. G. W. Carr, 83, Villiers Street, Dresden, Loughton, Staffs. The cost of malleable iron castings is something under 6d. per lb.—CYCLOPS.

**Monogram.**—E. R. (*Bermondsey*).—I am sorry to disappoint you, but monograms are costly to engrave, and the space they occupy cannot be spared. Those already given will furnish you with some idea of the method to be adopted in working out your own.

**Exhibitions.**—F. G. W. (*Kettering*).—There will be no "Work" Exhibition this year, and I am unable to tell you in what places local exhibitions are contemplated, as I am without information on the subject. Secretaries of local exhibitions should always send early notices to WORK, and then announcements of them could be made in these pages.

**Power to Drive Machine.**—IGNORANT.—If a machine takes 7 to 8 h.-p. when driven direct, when a line shaft is interposed between the two, there will be a very slight increase of power required, owing to the friction at the journals of this line shaft. The distance apart of the pulleys on the line shaft has nothing to do with it, except that, if they are far apart, there will have to be more bearings on the line shaft, and therefore more friction; also, if there was only *one* pulley on the shaft which both received and transmitted the power to the engine—the engine being on one side and the machine on the other—the belts would pull against each other and so relieve the journals of most of the friction. The friction will be very small if only the shaftings and journals are properly in line and firmly fixed.—F. A. M.

**Positives on Dry Plates.**—AMATEUR P.—Practically, it is not impossible to take such pictures on ordinary dry plates. The method used is the collodion wet plate process, either on glass or ferrotype plates, and the development by means of an acid solution of iron sulphate. Of course, positives may be made on Ilford plates as transparencies; but emulsion processes are unsuitable for the display of images by reflected light, which is a matter of necessity in the work alluded to.

**Bookbinding.**—H. W. (*Helston*).—Articles on bookbinding appeared in Nos. 6, 9, 57, 61, 65, 69, 72, 75, 80, and 85; and queries relative to the articles are answered in "Shop" in Nos. 14, 16, 17, 18, 32, 38, 45, 46, and 50.

**Registration of Designs.**—S. A. C.—It is possible that some papers on this subject, which may be useful to you, will shortly appear in WORK.

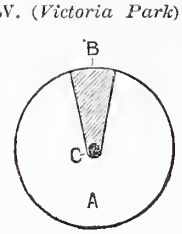
## III.—QUESTIONS SUBMITTED TO CORRESPONDENTS.

**Fountain Driven by Engine.**—C. A. P. (*Ealing*) asks:—"Can any reader give me any information how I could make a small fountain worked by a hot-air engine? I should like the fountain to throw a continuous jet of water about 18 in. high; the whole to stand on a base about a foot square."

**Marionette.**—C. A. P. (*Ealing*) writes:—"I should be glad if you could tell me how I could make a marionette, about 15 in. to 18 in. high, to dance like those at the Aquarium, on a miniature stage."

**Linen Buttons.**—W. L. (*Huyton*) asks:—"Will anyone kindly give me the names and addresses of the *best* linen button manufacturers?"

**Grooving Cane.**—A. W. W. (*Victoria Park*) writes:—"Can any reader inform me where I can procure a tool, and what kind of tool it is I require, to cut a groove in cane after the manner shown in section in the accompanying diagram, in order to place in the centre of the cane a piece of straight-drawn wire? The tool I require is one that will cut out the strip of cane to enable me to lay in the wire, and also replace that which I cut out."



Section of Cane—A, Cane; B, Piece to be cut out; C, Wire.

**Drilling Grindstones.**—T. A. D. (*Royton*) writes:—"I wish to ask if any reader of WORK can tell me what kind of system they have in those quarries where they make small grindstones, about 1 ft. in diameter and from ½ in. thick upwards, of drilling the holes in the centre? and if they are drilled on a machine or by hand? and whether they use ordinary drills or diamond-pointed drills? At the shop I work in they make a machine which is fitted with these stones in it to grind small moulding irons for joiners, and they have a square hole in them about 1 in. square, and we have to drill them out to 1½ in. round size. When we have drilled one hole in, it makes the drill too small for the next one. It takes all the edge off the drill where the stone touches the drill. We drill them on an ordinary drilling machine—a vertical one. We have had the drills hardened as hard as we could get them without breaking them. The stones come from the neighbourhood of Rotherham, in Yorkshire, and are of a soft nature. I should also like to ask if they are done with a machine, what kind it is, how it is worked, and by what means—whether steam, water, or hand—and what kind of drills?"

**Plan of the Heavens.**—M. D. C. (*Liverpool*) asks:—"Can any reader make a suggestion to utilise the plan of the Heavens given with the first part of 'The Story of the Heavens?' My idea is to have a stand with the plan in a frame with a swivel, to turn it round if required, and to take it off when not required."

## IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Bath, to Heat.**—J. H. (*Smethwick*) writes, in answer to ROUND O (see page 414, No. 130):—"If he could raise his bath high enough to get one of Truman's stoves in under it he could heat his water at any time or to any heat. He would have to raise it at each end 10½ in., the height of stove."

**Mail-cart Handles.**—C. M. (*King's Cross*) writes:—"In reply to query by ADIA (see page 414, No. 130) about mail-cart handles, he can get what he wants from Mr. H. Matthews, Baron Street, Pentonville, who keeps a stock of them already bent, or would bend them to pattern if a few pairs were wanted. Mr. H. Matthews can be recommended for bent timber of any kind."

## V.—BRIEF ACKNOWLEDGMENTS.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—H. B. P. (*London*); J. S. (*Longsight*); T. D. (*Liverpool*); H. E. (*South Norwood*); GRANT; W. F. (*Ascot*); CHATHAM; ENVELOPE; H. F. M. (*Ramsbury*); LITHO; H. H. (*Finsbury*); J. S. (*Hampstead*); F. H. (*Battersea*); T. J. S. (*Finsbury*); W. E. D. (*King's Lynn*); N. F. (*Gateshead*); W. C. (*Sharpness*); C. A. P. (*Finsbury Park*); J. O. (*Bradford*); SCARBORO'; ESOR; J. H. (*Bishophill*); E. A. P. (*Tollow*); F. F. (*Brixton*); F. R. (*Gosport*); W. F. (*Gateshead*); W. N. H. (*Bradford*); A. B. (*Rochdale*); STOURBRIDGE; L. S. L. (*Kirkcaldy*); WHITEFIELD; BARKIS; J. H. (*Smethwick*); W. R. (*Yeovil*); LEARNER; LUX IN TENEBRIS; P. R. (*Edinburgh*); F. B. (*Aldershot*); J. G. (*Edinburgh*); A. P. M. (*Notting Hill*); E. J. B. (*Dartmouth*); J. P. (*Belfast*); EUSTACE; R. (*Edinburgh*); J. W. (*Camberwell*); R. C. (*Glasgow*); MAINSAIL; W. H. (*London, S.W.*)

## MANUALS OF TECHNOLOGY.

EDITED BY PROF. AYRTON, F.R.S., AND RICHARD WORMELL, D.Sc., M.A.

**The Dyeing of Textile Fabrics.** By Prof. J. J. HUMMEL, F.C.S. With Numerous Diagrams. Seventh Thousand. 5s.

**Steel and Iron.** By WILLIAM HENRY GREENWOOD, F.C.S., M.I.M.E., etc. With 97 Diagrams from Original Working Drawings. Fifth Edition. 5s.

**Spinning Woollen and Worsted.** By W. S. BRIGHT MCLAREN, M.P., Worsted Spinner. With 69 Diagrams. Second Edition. 4s. 6d.

**Cutting Tools.** By Prof. H. R. SMITH. With 14 Folding Plates and 51 Woodcuts. Third Edition. 3s. 6d.

**Practical Mechanics.** By Prof. J. PERRY, M.E. With Numerous Illustrations. Third Edition. 3s. 6d.

**Design in Textile Fabrics.** By T. R. ASHENHURST. With 10 Coloured Plates and 106 Diagrams. Third Edition. 4s. 6d.

**Watch and Clock Making.** By D. GLASGOW, Vice-President, British Horological Institute. Second Edition. 4s. 6d.

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London.*

FOURTH EDITION. Price *7s. 6d.*

**Practical Electricity.** By Prof. W. E. AYRTON, F.R.S., Assoc. Mem. Inst. C.E. With Numerous Illustrations.

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London.*

WORK

*is published at La Belle Sauvage, Ludgate Hill, London, at 9 o'clock every Wednesday morning, and should be obtainable everywhere throughout the United Kingdom on Friday at the latest.*

ARE universally admitted to be worth a Guinea a Box for Bilious and Nervous Disorders, such as Wind and Pain in the Stomach, Sick Headache, Giddiness, Fulness and Swelling after Meals, Dizziness and Drowsiness, Cold Chills, Flushings of Heat, Loss of Appetite, Shortness of Breath, Costiveness, Scurvy and Blotches on the Skin, Disturbed Sleep, Frightful Dreams, and all Nervous and Trembling Sensations, &c. The first dose will give relief in twenty minutes. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

## WORTH A GUINEA A BOX.

For Females of all ages these Pills are invaluable, as a few doses of them carry off all humours, and bring about all that is required. No female should be without them. There is no medicine to be found equal to Beecham's Pills for removing any obstruction or irregularity of the system. If taken according to the directions given with each box, they will soon restore females of all ages to sound and robust health. This has been proved by thousands who have tried them, and found the benefits which are ensured by their use.

For a Weak Stomach, Impaired Digestion, and all Disorders of the Liver, they act like magic, and a few doses will be found to work wonders on the most important organs in the human machine. They strengthen the whole muscular system, restore the long-lost complexion, bring back the keen edge of appetite, and arouse into action with the rosebud of health the whole physical energy of the human frame. These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the Nervous and Debilitated is, BEECHAM'S PILLS *have the largest Sale of any Patent Medicine in the World.*

## Beecham's Magic Cough Pills.

As a Remedy for Coughs in general, Asthma, Bronchial Affections, Hoarseness, Shortness of Breath, Tightness and Oppression of the Chest, Wheezing, &c., these Pills stand unrivalled. They are the best ever offered to the public, and will speedily remove that sense of oppression and difficulty of breathing which nightly deprive the patient of rest. Let any person give BEECHAM'S COUGH PILLS a trial, and the most violent Cough will in a short time be removed.

Prepared only, and sold Wholesale and Retail, by the Proprietor, THOMAS BEECHAM, ST. HELEN'S, LANCASHIRE, in Boxes, 9½d., 1s. 1½d., and 2s. 9d. each.

Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*

A CYCLE HOUSE.

## A CYCLE HOUSE.

BY J. H.

STORAGE OF CYCLES—GENERAL VIEWS OF HOUSE—MAIN FRAMINGS—BOARDING—PORTABILITY—COST—QUANTITIES REQUIRED.

*Storage of Cycles.*—Cycles, and especially tricycles and tandems, are awkward things to store away in the little houses occupied by working people in the towns. Some kind of shed is indispensable. The wash-house, or scullery, or kitchen is out of the question. It is a pity to use the green-house; a fowl-house is not nice; so a special place is almost indispensable. Such sheds are advertised at somewhat high prices, prices that are prohibitory to many young cyclists. I will show how a shed can be made for less than half the price of one of these, provided the cyclist is a bit handy with common tools. I propose to describe in detail a fairly large one of my own, made a couple of years ago. It contains a cripper tandem, a cripper tricycle, and two safeties—one full-size, the other a lad's machine. The house measures 9 ft. by 7 ft. 6 in., and cost less than £3 for materials, and being well tarred will stand for as many years as I and mine shall be likely to want it. A house of half the size would hold a tricycle and a safety, or three safeties, and the cost would be reduced in exact proportion to size.

*General Views of House.*—The general construction of the house is shown in Figs. 1, 2, 3, 4. Fig. 1 is a roof plan, Fig. 2 a side elevation, Fig. 3 a front elevation, and Fig. 4 a perspective of the main framework, given to assist amateurs to a clear understanding of the method of its construction. It is a lean-to shed, a wall occupying one side. In my case the roof slopes *towards* the wall, but as in most instances it would be more convenient to allow it to slope *away* from the wall, I show it thus in the sketches. The low wall against which my house leans happens to carry an oblong rain-water tank on the top, and the rain runs off the roof into the tank; hence the reason why I so built it.

*Main Framings.*—The main frames of the house are made of spruce quartering, having a cross section of 3 in. by 2¾ in. They are these (Figs. 1, 2, 3, 4):—

Four uprights (A, A, B, B), four horizontals (C, C, D, D), two roof horizontals (E, E), and four rafters (F, F). These are all mortised and tenoned strongly together, as I will show in detail in the next article. Upon the way in which the work is done, the stability of the house largely depends.

There are also two uprights (G, G) of the same cross-section, 3 in. by 2¾ in., that form the posts of the door. Also two uprights (H, H) to afford a central support to the boards on that side of the house, and two uprights (J, J) and a cross-bar (K), between which a window-sash is placed.

There are two joists (L, L), having a cross section of 6 in. by 1 in., fixed on and between the horizontals, D, D. These carry the flooring boards, of ¾ in. spruce. The house is therefore quite dry and clean.

*Boarding.*—The framework is covered over with spruce boards, ⅜ in. thick by 9 in. wide, overlapped about an inch at the joints, and nailed to the quartering and to each other. The roofing boards are covered with felt, well tarred. The door (N) is made of 1 in. spruce boards battened together.

*Portability.*—This house is built in such a way that it can be taken down and removed with the least waste of material possible. It is also economical, as the following account will show.

*Cost.*—The cheapest way to buy timber in moderate quantity is to purchase it in a deal or deals, and pay for sawing. Spruce deals measuring 11 in. by 3 in. cost fourpence per foot "run"—that is, fourpence for each foot in length. Sawing costs from 2s. to 2s. 6d. per 100 ft. superficial. Now the quartering is made by cutting a 3 in. deal into four strips—that is, three shallow cuts. ⅜ in. boards are made by cutting a 3 in. deal into six—that is, five *deep* cuts. In the first case a 12 ft. deal would cost at 2s. per 100 ft. about 2½d. for sawing. In the second a 12 ft. deal would cost 1s. 1d. for sawing.

Now for quantities required.

*Quantities required.*—Running through the dimensions given in the figures, we see that about 160 ft. of 3 in. by 2¾ in. quartering are required. Dividing this by four, it means that 40 ft. of 11 in. by 3 in. is wanted, and this will cost 160d. plus, say, 9d. for sawing—total, 14s. 1d.

Of ⅜ in. stuff we shall want about 220 superficial feet, equivalent to about 40 ft. of 11 in. by 3 in. at fourpence, costing 13s. 4d.; sawing this will cost, say, 4s. ⅜ in. flooring board, 7 in. wide and 1 in. thick, costs from ¾d. to 1d. per foot run, according to quality. About 150 ft. run will be wanted for floor and door—say, 150 times ¾d.—roughly, 9s. 6d.

An old sash can be bought for 1s., a pair of hinges and padlock for 1s. 6d., nine yards of felt for 4s., two gallons of tar for 1s., and six pounds of various nails for 1s., so that our account stands thus:—

| | s. | d. |
|---|---|---|
| Quartering | 14 | 1 |
| ⅜ in. stuff | 13 | 4 |
| Sawing do. | 4 | 0 |
| Flooring, etc. | 9 | 6 |
| Sash | 1 | 0 |
| Hinges | 1 | 6 |
| Felt | 4 | 0 |
| Tar | 1 | 0 |
| Nails | 1 | 0 |
| | 49 | 5 |

And every scrap of this timber will be new and clean, and sawn to thickness. The prices, too, are not the lowest possible. In some seaport towns lower prices can be figured.

In the next article I shall conclude by giving a detailed description of the methods of union adopted in these various parts, using the same reference letters as those employed in the present article.

## REPAIRS TO FLUTES, CLARIONETS, ETC., THAT MAY BE DONE BY AN AMATEUR.

BY B. A. BAXTER.

INTRODUCTION—PADS AND PADDING—SPRINGS—CLARIONET MOUTHPIECES—REEDS—SOME REMARKS ON THE CLARIONET AND ITS HARMONICS—CRACKS IN THE WOOD.

THE flute-player, or, indeed, any of those musicians who play upon the instruments grouped under the term of "wood wind," have need of mechanical ingenuity, in order to effect trifling repairs to their instruments, which are very delicate, and sometimes complicated pieces of mechanism.

It is not intended to give here any instruction to effect radical alterations in the instrument or its fittings; any directions I shall give will be of a conservative character, and I most strongly advise the most thorough and careful examination of any defect before the player attempts to cure it. When a would-be player first invests in a new instrument—new in the sense of his own inexperience, though it may be second-hand—he cannot always afford to buy the best instrument of its class, nor one that bears the warranty of the firm who sells it. By the way, the mere imprint of maker or seller's name is not a warranty of perfect condition. The beginner may have to be content with one of those instruments imported from France or Germany, which are sold by music warehousemen and dealers generally. These instruments are usually good; they bear no name and are sold as received, the dealer accepting no responsibility on the subject—good, I ought to say, according to the price; and if the young flautist can get a friend with experience to select his flute, he may be well content to have what is called a warehouse instrument.

But we will suppose it bought, and some progress made in learning. Some tones appear too loud, some harder to produce than the rest, some too faint to be in keeping with the rest, some too flat, some refusing to sound at all. Now, some of these are due to the player's inexperience, some are curable defects, though I shall not pretend that all are within the control of the amateur.

*Pads and Padding.*—The flute or clarionet will not sound aright unless the pads close perfectly the holes they are intended to cover. Pads may be bought at moderate prices, according to material and size, from 3d. to 1s. per dozen. First test each piece of the instrument separately by stopping one end and the finger holes, blowing into the other end: if a little water is placed on each pad it will soon be evident if any of them leak. Look if there is any chip or dirt lodging in the hole or on its edges. See if the springs act perfectly to keep the key closed, and if no fault is discovered there the defect is probably in the pad; some of them are made of a skin or membrane, like gold-beater's skin; this in a short time wears on the sharp edge of the wood. Select a new pad from your stock of the proper diameter and thickness, and, having removed the key, make it hot at the end where the pad is fixed; this may be done in a gas-flame, or a composite candle will give heat enough. Avoid holding the key *above* the flame: this will blacken it, so that it will be difficult to clean perfectly; hold the key close to but below the flame, in order to warm it. The old pad will be easily removed and the new one fitted with either shellac, good sealing-wax, or even bicycle cement, preference being given to the first of these, and either being used very sparingly, for we do not want cement or anything else to spoil the softness of the contact of the pad with the instrument. See that the pad fits well and replace the key at once, while warm; the pad will more readily adapt itself to the hole it has to cover.

*Springs.*—The springs of each key, though differing in size, should offer about the same resistance to the finger, though this must be quite secondary to the duty of the spring in keeping the key air-tight. In open keys, which the finger and not the spring closes, the spring can be as slight as may be desired. To weaken over-strong springs, I have found that a pin or a piece of wire placed between the spring and the key, and gently pressed towards the root of the spring, will lessen the curvature, and, therefore, its resistance. As this can be done without taking the key off, and the effect can be felt at once, it is a very good way to regulate the springs. It is not available for needle-springs, which,

however, do not so often require regulating. These I have at times regulated by merely pinching with pliers, so as to slightly reduce or increase the curvature as required. All this foregoing is applicable to any of the wood-wind family.

*The Clarionet.*—Now a few words about the clarionet, with which I am more familiar. A flute is a mere tube, in which a column of air is vibrated by the skilful way in which the player directs a stream of wind, neither wholly into nor outside the tube; the varying length of the air column is effected by the fingering.

In the clarionet, however, we have a reed vibrating outside an aperture smaller than itself, through which, therefore, it cannot pass: opening and closing this door-like arrangement with rapid, yet periodic, alternation, it produces a tone more or less musical. The tube, however, asserts its power to modify both the rapidity of the reed's movement and the quality of tone produced. Now, to do this it is important to have a good mouthpiece. The clarionet mouthpiece is a partly turned and partly carved wooden tube, in which the cylindrical hole in the end is gradually reduced to an aperture in the side of the mouthpiece, the reed resting on an almost flat surface, reduced from the original turned exterior.

A little consideration will show that this almost flat surface must be curved so as to allow the reed enough liberty of movement, that the shape of the curve must be such that the reed by its own flexibility, aided by the player's lips, will close the aperture. Hence the exact shape of the almost flat surface of the mouthpiece on which the reed rests depends on the stiffness of the reed and the strength of the player's lips. Here, then, is the reason of the difficulty in "laying" a mouthpiece, as it is called. Three varying factors contribute to the result, and must be brought into suitable relation to each other. Let no one think I wish to set all the young clarionet players to alter their mouthpieces; I do not. Had my reading some twenty years ago extended to repairs of this kind, I should have done much less re-laying, and better than I have sometimes succeeded in doing it.

Never try to re-lay a mouthpiece unless you have a good reed to try it with—a worn-out or badly cut-down reed will not do. Be sure to have the curvature of each side alike, or no certainty of tone can be expected, but an occasional piercing shriek may be foretold. After these warnings, you will expect to be told what to do and how to do it. If the clarionet will utter the lower sounds well, the opening between reed and mouthpiece is long enough; if it is hard to get some of the upper tones, the lay is too straight; if the very highest tones are impossible, it may be the fault of the reed, for I have proved that a reed cannot be made to vibrate more quickly by the tube to which it is affixed, though it can, and is, made to vibrate more slowly by the addition of the tube. I satisfied myself as to that by cutting the back out of a mouthpiece, so that there was really no tube; trying various reeds, I found various pitches, rising according to pressure of lip and wind, but in no case could I coax a reed to give a higher pitch on the complete clarionet than was possible on my mutilated mouthpiece. In order to prove whether a mouthpiece has its sides alike, the best plan is to obtain a piece of plate-glass, and holding it in contact with the flat part, test the opening with pieces of sheet-metal of even thickness, or pieces of note-paper, or even a postcard; if either lies obliquely, then the curvature is not alike on each side. In order to give some assistance as to the curvature of the mouthpiece, having measured a very satisfactory one, I find a white postcard will enter $\frac{3}{8}$ in., that the paper on which WORK is printed will enter $\frac{2}{8}$ in., and a buff postcard nearly $\frac{3}{4}$ in., while the reed and mouthpiece are in close contact an inch from the end of mouthpiece. But, as I have said, the reed and the lips of the player are factors in the result. A stiff reed requires less aperture; a flexible one more. By all means choose a reed as stiff as can be played with comfort; it is finer in tone and is more durable—moreover, it makes the high notes more certain.

*The Reed.*—Many players are not able to secure good reeds without trial; this is out of the question, but we may *look* at the reeds when we buy them. Hold a well-made reed up to the light, and the stouter part is seen to be opaque, while the thinner part is semi-transparent; that the change is gradual and equal on each side of the centre; see also the colour, which is an evidence of the ripeness of the cane—like the straw of corn, it is at first green, changing to a yellow, from lemon-yellow to orange or buff; avoid all greenish reeds or very pale lemon colour; also avoid dark yellow or buff-coloured cane. One is immature; the other is over ripe, and gives a splendid tone, but, alas! it is for a very little while, the cane soon losing the elasticity necessary to the best results. Try, therefore, to get reeds of a medium yellow tint; if the grain is well-marked, like a piece of wood, so much the better. A good reed will be found to retain its smoothness when wetted. If any get very rough when first put into use, throw them away, and avoid making your lips sore. A reed too stiff may be rubbed down carefully with a piece of "water of Ayr" stone moistened with water, which also, I ought to say, is useful to finish the lay of a mouthpiece, after the finest files have done their best to attain perfection.

*Harmonics.*—All the upper tones of wind instruments are due to harmonics: in the flute the octave is the first, and in the clarionet the twelfth is the first interval obtainable as the result of harmonics. The clarionet produces the odd series of harmonics; and, with the exception of *stopped* organ-pipes, I believe it is aloue in this respect.

*Cracks in the wood* are best prevented: care in the use of either of these instruments will often prevent a crack which carelessness would certainly produce; avoid any unnecessary moisture, and wipe out the instrument as soon as playing is over; do not expose it in a moist condition to the influence of heat, and treat it to a trace of oil occasionally, which may be of a drying character, in the iuside. Be sure not to let any drying oil go on the pads; let them remain clean, or if stiff from watery moisture, use a little vaseline, which may also be used to lubricate springs, but apply it very sparingly, or the instrument will collect dirt very quickly. If a crack should be noticed, it will probably begin on the outside: stop it at once. If the wood is greasy, perhaps marine glue is the best, or shellac varnish; but if not greasy, fish glue or best Scotch or Cologne glue would do well. If possible, get a turner to turn a shoulder and put on a ferrule; but by taking the precautions I have indicated, it is to be hoped nothing more will be required.

The above, I trust, will be found a very fair summary of the extent to which an amateur may reasonably proceed in repairing the two instruments mentioned.

## BOOT AND SHOE REPAIRING.

BY WILLIAM GREENFIELD.

### How to Re-welt and Re-sole Hand-sewn Work.

In this, my last article on "Boot and Shoe Repairing," I will deal with the two above subjects. They are certainly the two hardest that I have as yet put before you; but being the most important, or the two nearest approaching the making of a boot, it would be hard to say how important a part they will take in giving you a comprehensive knowledge of the more practical part of boot and shoe making.

You ought by this time to be pretty used to using the awl and thread, therefore, although the hardest, they ought to come far more easy than some of the minor repairs did, for in shoe repairing there is seldom a week passes without there are jobs of some kind to give a little practice and keep the hand in trim. But to proceed with the work in hand. It should be borne in mind that a last must always be put in and fitted well to the boot or shoe, or you will not be able to make them look well, and there is a *chance* of making them smaller. Pieces of stout leather can be put down on top of the lasts, or even pieces of bundle-of-wood stick will do, tapered at one end, and the thin end knocked in first; but then this must be done carefully, or the vamp may break just in front of the lacing. Fitting them up well in this form should make the bottom solid all over, and keep them in their proper shape.

A thin, long tack must be put in the back of the boot to keep the last in its place, as at A, Fig. 1; then put the sole and welt part in water, and when it is nicely wet take it out, wipe it, and cut the old sole off. This is done by putting a knife between the sole and welt at B, and continuing right along, round the toe, and down the other side to C. The old sole can then be cut away, cutting across from D to E if it is going to be a riveted or pegged graft, as shown in the first article (see WORK, Vol. III., page 113, otherwise No. 112), or from F to G if it is going to be a sewn graft.

In either case a small hole can be made in the old leather at H, and a piece of waxend put through, that it may be drawn down flat on to the top of the heel, securing it there by tying the thread round the nail at A. This keeps it in position while grafting, and also sewing in the welt. If you intend to welt it all round, carefully cut the old welt away from I to J, and take away, *pro tem.*, the bottom filling, K.

The next thing to be done is to fit the welt, which is a long strip of oil-dressed leather (price from a 1d. per pair). They must be buffed on the grain side, cut in two straight down the centre, tied in a knot, and put into water to get wet—thoroughly soaked, in fact, for they have to be used wet. But before they are ready for use they have to have an angular piece taken off the grain side, as shown at A B, Fig. 2. This will, when turned over (that is, grain side down), show an end as Fig. 2, A, and this is the position in which it is held while it is being sewn in.

You proceed with the sewing as shown in Fig. 3, starting by putting the thread in at A, then halving the thread, as shown before, and making a hole at B, and while the awl is in, place the welt against the upper at its point, and make a hole in it at I, as shown by the arrow in Fig. 2, A. You then put the bristle through first, that is in the left hand,

and then the one in the right, and pull them both out, changing the bristles by this means into the reverse hands, and set the stitch as before explained. This you continue, as in Fig. 3, until you reach the old welt on the other side.

To sew in the welt, use a sewing-awl and a thread about the same substance; this, with a fair amount of wax, as the two ends have to go through the same hole, makes it solid.

When the welt is sewn in, hammer the seam down all round, giving firm blows, so as not to break or bruise it. Then carefully skive off any surplus stuff above the seam that may in any way make it uneven or clumsy, but do not cut near enough to the seam stitches to weaken them.

For repairs it is only necessary to skive the waste part (that is, the ends) of the welt a little thinner after they are sewn in, though it can, and therefore should, be done first; but a novice is apt to make them too thin, and weaken it where it should be solid, having to stand against the splice or graft in the sole. A piece of tapered bone should now be rubbed round between the upper and the welt, to make the welt flat to receive the stitches which the sole will have to be stitched on with. The edge of the welt must now be rounded up to the shape required. Generally it does not need to have much taken off, only just a little here and there, to make it a good shape, for a pair of welts when split in two is nearly always the necessary width, but at places the stitching somewhat contracts it, and thus leaves prominent parts, which are best cut off, and, as shown by the dotted line in Fig. 3, is always a little too wide at the waist.

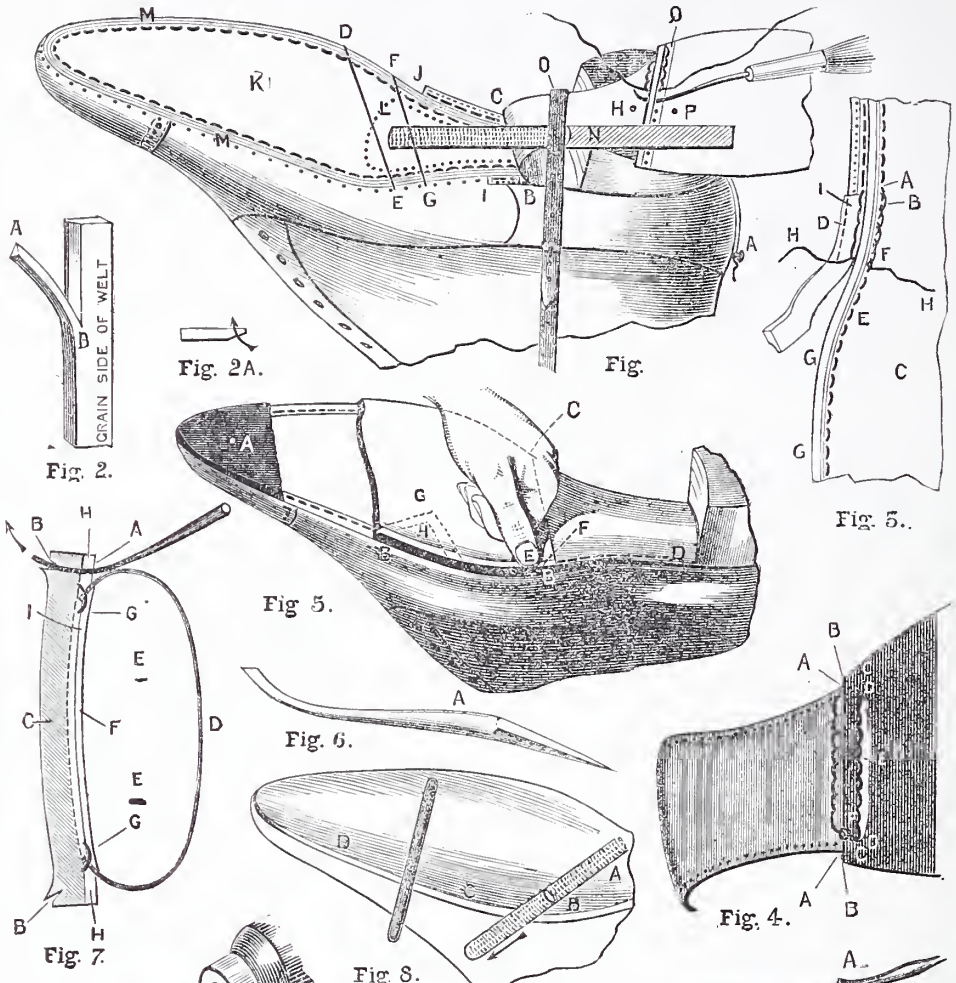

Fig. 1.—Boot showing Sole and Welt off and Waist turned back ready for Grafting, and Position to hold it while doing so. Fig. 2.—The Welt, with Piece nearly taken off to prepare for Sewing. Fig. 2 A.—Amount of Welt taken up in Sewing. Fig. 3.—Section of Boot, showing how to Sew Welt in. Fig. 4.—How to Sew Graft. Fig. 5.—Showing how to Fit, Stitch, Sew, etc. Fig. 6.—Blade of Stitching-awl. Fig. 7.—Transverse Section of Boot, showing Interior and Action of Awl in Stitching (A); B B, Channel; C, Sole; D, Upper Leathers; E E, Interior; F, Insole or Welt Stitch; H H, Welt; I, Bottom Filling. Fig. 8.—Showing how to rub down Channel. Fig. 9.—Fudge-wheel. Fig. 10.—Section of Boot, showing how to Stitch and Prick them up. Fig. 11.—Double Iron, showing Guards.

If the old bottom filling is good, paste it in again at K, Fig. 1; if not, replace it with new.

Felt is used for this purpose; a pennyworth will fill three or four pairs. In this case cut a piece a little larger than the old, and paste down the shank (generally a piece of skived leather, which reaches from under the heel to the dotted line, L, and just the width of the waist), then paste the new piece of felt in the bottom, hammer it in well all over, and let it dry while you do something else, and when dry skive off the edge all round at M M, making it level with the welt stitch and the centre, K. It is then ready to receive the sole. Prior to placing the sole down, the graft must be made—that is, if you intend to make a sewn graft.

To do this, it is all important to have the old leather cut straight across, and straight through from A to A, Fig. 4, and also the new sole from B to B; then draw a line from C to C about $\frac{3}{8}$ in. wide, and a second one, about $\frac{1}{8}$ in. from the first, reaching from D to D.

From D to D on the first line cut through into the leather about $\frac{1}{16}$ in., holding the knife quite upright; this can then be opened with any blunt instrument to show how far you have cut through. Then from this channel cut one side away to where the second line is (this is towards the toe), holding the knife this time quite slanting; this is to make a recess to receive the stitches, and make a flat seam to the graft, as shown at E.

From D to D make a series of holes (about five to the inch) with a sewing-awl, placing the point flat on the bottom of the recess and putting it through until its point is just seen in the edge of the leather, about $\frac{1}{16}$ in. from the grain edge.

All this should be done on the flesh side, with the leather fitted in the same way as shown in Vol. III. of Work, page 113, *et seq.*; with one exception—that is, this being sewn work the leather has to be used a little more wet.

The boot is now put on the knees, with the toe to the left and the back part on the right knee, in the position shown in Fig. 1, and, as also shown there, with the old waist tied back. The new sole can be put against the old leather, and an old rasp put along on top, as shown at N, and the strap or rope put round the toe of the boot you are wearing, and round the waist of the one you are repairing, as shown at O, and O passing over the rasp, which will, as it presses upon shank, L, the old waist, H, and the new sole, P, keep them all solid while the graft is being sewn.

The graft should be sewn with a good strong thread—say about fifteen strands of No. 9 Patent, or equal to it if a stouter hemp is used—and plenty of wax should be worked into it before it is twisted.

The sewing should be commenced at Q, and continued across to D F, Fig. 4, tying a small but firm knot at F, as each end must be particularly solid, and for this reason it is quite as well to make two short threads, and using one for each graft—it is better than starting and ending with a knot; and another thing is that novices wear out a thread much quicker than an experienced workman does, as it is handled more, and not pulled through without occasional snaps and jerks, and this seam must be solid even at the expense of neatness, which if riveted cannot so well be attained.

It will be seen that the grafting is done on the top of the heel; this is because it is the most convenient place according to the position of the old leather, and also to get a flat surface to work upon—viz., the old top-piece.

If it is found difficult to keep the sole firmly in position by means of the rasp only,

a long rivet can be put in at H, and another at P. They will only go through into the old lifts, as the heeling should be left till after the soling is done, and the two holes can soon be rubbed out in the finishing.

The graft sewn, the whole of the bottom, K and L, and also the new and old leather, H and P, should have a thin coat of paste. The sole can now be put into its place, pulled over from the toe, and a rivet put through, to keep it in position, as at A, Fig. 5, and one through the hole in the sole that was called P, on the other side of it, in Fig. 1.

This done, hammer it evenly all over, and then pare it up at the edge, close to the welt, the whole way round, as it is shown at B B, Fig. 5. This, as the sole is wet, can, with a little care, be easily done without cutting the upper part, and should be done so as to form one even edge all round, and be kept square or at right angles with the flat of the welt. A line can now be drawn with the compasses all round, about $\frac{1}{16}$ in. from the edge, and upon this line the channel is to be cut to receive the stitch.

To cut the channel the boot has to be held between the knees, with the toe towards you, and a sharp-pointed knife must be held between the thumb and finger, letting the second finger rest upon the top edge of the sole. The knife will then be somewhat in the position of a pen while writing, but it must be held firm, and its exact position with the flat of the welt should form an angle of about 50°. It should cut right through epidermis (the grain) and into the dermis (the fibrous and wear-resisting property) sufficiently to let the thread lay well into it. This will be nearly half-way through the leather, whatever the substance may be, as it is the substance of the sole that will have to decide the thickness the thread will have to be that is to lie in the channel.

The thread being embedded into the firm part of the sole gives not only solidity to the stitch, but leaves the scarf-skin, or grain, free to form a covering for the stitch.

When the channel has been cut, as from B B, and round the toe to C, Fig. 5, it can be opened with any blunt instrument. This is that you may see that the point of the awl comes out in the pit or centre of the channel, and to give the stitch room to fall into it while you are stitching. The grain edge of the channel, G, can be turned over for about two inches. This is to prevent the stitching-awl from notching it, which would make it very irregular and unsightly when finished. When you have set about a dozen stitches, again repeat the process by passing the left-hand thumb-nail along from the last stitch for another two inches.

One of the most essential things to give a good result, and save disappointment, is, in rounding up the sole, not to cut it too close to the welt, more especially on the outside, unless the wearer wears most on the inside, then, of course, the system is reversed.

Prior to stitching the sole on (which is generally done when a boot has been welted) the waist will have to be sewn down with the sewing-awl. It does not matter so much about a channel being cut in the old leather, as the waist can be blacked, which helps to hide the stitch, though if the leather is sufficiently thick to admit of it, it will make a much neater finish.

The sewing is started at D, Fig. 5, and the sewing-awl used till you get to B, the first stitch on the new leather. Then the stitching-awl is used; but, before I go any further, I must tell you that at these two points, B and C, the sewing and stitching should be so arranged that a stitch is set from the old to the new leather, across the graft at B, and from the new to old at C, so as to make these (the weakest points) quite solid.

The stitching-awl is put into the same sort of handle, and is a similar instrument to the sewing-awl, with the exception of it being flat the reverse way, as shown in Fig. 6. In fact, it has now almost taken the name of "the square awl." It will be seen by this figure that when put into the handle it cannot be straight, but has a bow and pitch, at A and B. This makes it more handy to get into awkward places, and gives from pressure on the handle a power that could not otherwise be obtained.

The action and use of this awl are very peculiar—it must not be wriggled about as explained for the sewing-awl, but passed through by one rapid and almost straight jerk.

First, the boot is held on the knees by the strap, toe towards you, on its side, with the sole to the left, and the upper to the right, with the thumb of the left hand pressed firmly against the bottom of the sole, just beyond where the point of the awl is to come out, as shown by E in Fig. 5. The awl is then laid on the upper, with the point against the flat of the welt. It must then be pushed through by one sharp push, just dropping the elbow a little in doing so, sending the point through into the channel that was cut in the new sole, as shown at F, Fig. 5, and also at B B, Fig. 7, the curved motion being indicated by arrow at the top, B.

By looking a little at Fig. 7 a good idea can easily be gained of how a hand-made boot is really put together. It is what a boot would be were you to cut it right through in a transverse direction at the centre of the sole. The key to the various parts will be seen in the description of the diagrams.

The stitching is continued right round, as far as the new leather goes, then the old is sewn as on the other side. Then the channel is again opened, and the stitches that are within it rubbed down well with the bone. Here and there a little paste is put in. This is rubbed in even all round, by putting a piece of rag over the right thumb, and the nail put in the channel, and rubbed up and down all round.

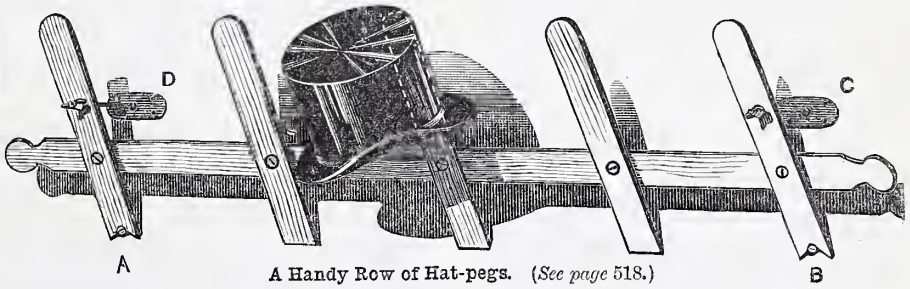
The boot is then held in the left hand, with the heel towards you, and the channel is laid down with an old file, by taking strokes in an outward direction from the centre of the sole, encroaching each time upon the channel in a direction towards the toe, as shown at A B, Fig. 8, which is, of course, continued all round.

The boot is then held in the same position as at first, and a bone or long stick is held with one end in each hand, and the channel is rubbed hard up and down from C to D, and so on until the whole is well rubbed down. Both these actions throw the thin narrow strip of grain (H, Fig. 5) over on to the edge, and it forms a sort of burr all round.

The boot is then held with the toe towards you, and with the back of the knife the edge is scraped in an upward direction to throw this burr on to the top of the sole. The knife is then held flat on to the sole, and the burr cut off level with the top of the sole. The stitches are then rubbed down a little on the welt side with the tapered bone, wetting with the mouth a little every now and then while using it. The bottom is then well and evenly hammered all over.

Before the stitching is commenced (as the stitch is wanted to show up bold on the welt) the fudge-wheel (Fig. 9) should be run round. This will make an impression on it as though it were stitched, and if the awl is put in exactly in the wheel-marks it will do a deal to make the stitch regular.

But to get a bold and even stitch this is not all that is necessary, for there is a mode of setting the stitch that is the principal factor in producing this *desideratum*. Each time that the awl is taken out put the left-hand bristle in first, as usual, and in putting in the other one, on the right side, let it pass on top of the other. This will throw up the stitch towards the edge, and if carefully done each time the stitches will form one straight line, as shown by the diagram (Fig. 10). The stitch can be set at, say, 12, 14, 16, or even 18 to the inch, according to work, but 14 will do well for ordinary work, while 18 is seldom necessary for repairs.



**A Handy Row of Hat-pegs.** (*See page* 518.)

After the stitches are rubbed down, the wheel (first warmed) can be carefully run round, letting each cog run between each stitch. This will, in every sense of the word, prick up the stitch, or a prickstitch can be used between each stitch, as shown by A, Fig. 10. The thread should not be twisted much.

The boots are then finished in the same way as described in Vol. III., page 113, *et seq.*, with the exception of ironing up with a double iron, instead of a fore-part iron. A double iron (Fig. 11) is in reality a jigger and fore-part iron combined; the guard A being run on the welt side, and the guard B on the sole side.

For the heeling and other details I must again refer you to the first paper in No. 112, and those that have followed.

And, so saying, I finish my series of six papers on repairs; and six more are in preparation on making, in which I will try my utmost to bring you on—as in these—in progressive form, till you are able to make and repair boots and shoes, not only good enough for yourself, but so that you may at any time, should it be necessary, or to your advantage, be able to take work from others, and recompense yourself in the way that all who try deserve to be recompensed.

## A HANDY ROW OF HAT-PEGS.

BY J. C. KING.

We all like something we can make in the way of useful household furniture, especially if it can be made without trenching too much on our spare time and spare money; and if it be with some practical advantages we are rather proud of showing it to our friends and expatiating on its merits. During the 1889 Exhibition in Paris, when rents were so high for visitors, the rooms and entries of many of the humbler dwellings were found to be scantily provided with hat-pegs and stick-racks. The S-hooks with knobs were few or absent, which was so much the better for the hat, which somehow so easily comes off that form of hook, or, if it stays, receives a bulge imparted by the knob.

Nailing up a wooden rail for hooks in a French wall leads, in point of fact, to the creation of dilapidations, for which the owner of the apartment does not forget to make you pay on leaving, if the nail does not come away long before, and make you wish you had put your hat on the bed-post or the table. Some friends staying in Paris during the Exhibition found no hat-pegs at their lodging. Something had to be done, and that quickly. The handy man of the family went out, and soon brought back materials: a piece of pine 5 ft. long, 2 in. by 1 in. size, and six pieces 12 in. long, 1¼ in. by ⅝ in.; six screws 1½ in. long, and four screws 3 in. long; and two bits of copper wire 12 in. long. A file, gimlet, hammer, screwdriver, chisel, and sand-paper were part of this young fellow's belongings, so the hat-pegs were made by screwing the short pieces on to the long piece, as shown in sketch; rounding the ends at top and notching the two end pegs at bottom, as shown at A, B, and at the distance of one-third from the top of end pegs boring a hole for the copper wire, which was fastened to two wedges of wood securely fixed in the wall, and a brass screw turned tightly into the wedge, with a leather shield to save the wall from ragging up. Two pieces of copper wire looped under the screw-heads, and held tight against the leather, as shown at C, D, fixed it. The whole concern rested on two screws and hung on two others, with the top ends about six inches from the wall. The whole job only took half an hour, and served for months for hats, coats, and dry umbrellas; and when the lodging was left the room owner gladly gave two francs for it rather than have it unscrewed from its place.

I must not omit that it was admired by visitors so much for its handiness that one of the party gave it a stain, to look like mahogany, of red and black ink mixed—very little of the latter—and some gum to stop the grain; and a coat of spirit varnish made it look like a "fabrique de Paris."

## A BOW SAW FOR DEEP CUTTING.

BY OPIFEX.

Introduction—Advantage Claimed—Materials—Construction — Dimensions — Sides — Cross-piece—Levers—Handles—Tightening up.

Finding the ordinary pattern bow saw to be unsuitable for a special piece of work which required rather deep cutting, I lately made the tool here illustrated, and as it answered its purpose so satisfactorily, I offer the suggestion, hoping it may prove useful to some of the readers of Work.

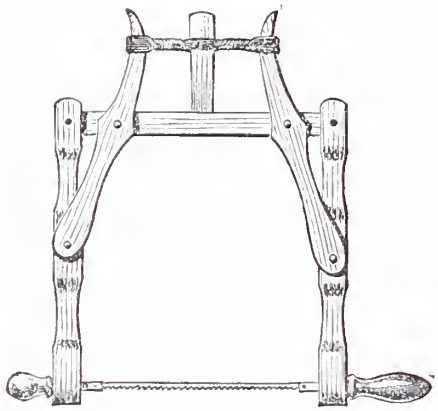
The *advantage claimed* for this saw is that it is twice as far-reaching as one having the cross, or fulcrum piece, placed in the usual position, which is, I think, a point of considerable importance to those who do not possess a band saw, etc.

*Materials.*—All the woodwork is of good, close-grained beech, which should be well seasoned and free from shakes of any kind. The only other items are four small bolts, 2 in. by $\frac{5}{16}$ in.; four washers to match; two copper rivets, 1 in. by $\frac{3}{16}$ in.; about 36 in. of strong clock gut; and, of course, the handles and saw blade.

The *details of construction* will be easily gathered from the drawing, and I shall not occupy more space than is necessary to describe them very briefly.

The *sides* of the frame are 15 in. by 1¼ in. by $\frac{5}{16}$ in., but these dimensions may be varied proportionally to suit any size of saw—a remark which also applies to all portions of the saw.

The *cross-piece* at top is 15 in. by 1½ in. by $\frac{5}{16}$ in., and is mortised at each end into



A Bow Saw for Deep Cutting.

the sides, the tenons being held in position by a rivet passing through the centre of each. The shoulders of the mortises should also be slightly rounded and the joints made an *easy* fit, so as to allow of a certain amount of give-and-take movement when tightening up and slackening the saw.

The *lever pieces* may be of ½ in. stuff, and for these the wood should be carefully selected, that the grain may run perfectly straight. They are attached to the sides and cross-piece by the bolts already described, the squares of which should be filed round and the nuts fastened up with washers at the back.

The *saw handles* may be bought at any tool-maker's, etc., for about 1s. 3d. the pair; or they may be easily made, as they consist of two beech handles fitted with brass shanks, having a slit in each to receive the onds of the saw, which is secured in position by a small pin passing through the brass shanks.

The shanks pass through suitable holes—which should be carefully bored with a clean-cutting bit—in the lower ends of the side pieces, as shown in the sketch.

*Tightening up.*—Holding the upper ends of the levers as tightly as possible with the hand, bind them round with six turns of the clock gut, knot the ends firmly, and insert the "tightener," which may be 6 in. by 1 in. by 1¼ in., and slightly tapered. Give two twists to the gut, and the saw will be found to be sufficiently rigid.

## A NOVEL USE FOR PHOTOGRAPHS.

BY ALEXANDER MARTIN.

Introduction—Advantages and Disadvantages—Description and Construction of Shelves—Mirrors — Securing Photos — Mounts—Candle Sconces—Medicine Cupboards—Conclusion.

*Introduction.*—In this novelty-loving age there are constantly being produced all kinds and conditions of things, claimed by their makers as being new and novel. Very often the novelty is of such a nature that after the freshness of the idea has passed away the article loses its only charm, and is thereupon laid aside in the lumber-room or destroyed. One novelty, however, recently seen by the writer, and no doubt by many of our readers as well, is of a more permanent nature, and one, he ventures to think, will have a long lease of life. It consists of using photographs as a means of ornament: little shelves, mirrors, cupboards, etc., for hanging on the wall are decorated with carte-de-visite, cabinet, or other sized photos. These little articles are in great request in every house, as by their means, when of pleasing shape and harmonious colour, little odd spaces of wall may be filled up and made interesting. The photos, again, are an additional attraction in themselves, and increase the interest with which such things would be otherwise regarded.

*Pros and Cons.*—It may, perhaps, be urged as an objection to this use of photographs that those placed on view will become so well known that they will be disregarded. But they may easily and readily be changed as often as desired; every day fresh faces may meet the eye, and even though not changed often, there is a subtle beauty in a well-executed photograph which will long retain its influence on the beholder.

These articles are particularly pretty when enamelled with any of the delicate shades of Aspinall's enamels; so any wood that is most convenient may be used in making them up—even different woods may be used in the same job without detriment, as all will be coloured alike with the enamel. This is an advantage which will be duly appreciated by many.

*Description and Construction of Shelves.*—The little bracket shown in Fig. 1 is of very simple construction; its back board is all of one piece of wood, ⅝ in. thick, shaped as shown. The little shelf is placed against this back board, and supported by a shaped bracket underneath. Both shelf and bracket are fastened from behind with screws. The back board is drawn one-eighth full size, so that in making it, each measurement from the drawing in Fig. 1 must be multiplied eight times. The little shelf is 10 in. long by 5 in. broad, and ½ in. thick; and at each of the front corners there is a quarter circle of 2½ in. in diameter cut out. The bracket underneath is also ½ in. thick, and shaped as shown.

The illustrations, it may be said, will all be found grouped together in a full-page cut. The smaller illustrations are mostly drawn on one-eighth scale, or on a scale of 1½ in. to 1 ft. The diagrams exhibiting working drawings of different parts and modes of construction are drawn full size.

*Mirrors.*—The mirror shown has bevelled edges; this is the usual kind of glass for such articles, and though costing more money than plain glass, is well worth the extra cost. Bevelled edged glass is so well finished at the edge that ⅛ in. is sufficient "cover" for it—*i.e.*, the opening for the glass should be

$\frac{1}{8}$ in. all round *less* than the exact size of the glass. The opening in this bracket is $7\frac{3}{4}$ in. by $4\frac{3}{4}$ in., to accommodate a plate 8 in. by 5 in., and it may have a $\frac{5}{8}$ in. bevel. A section of the rebate necessary for the glass is given in Fig. 3, where a blind back is shown sprigged in behind the blocking, keeping the glass in position. Care must be taken that the mitres of the glass bevel fit the corners of the opening as nearly as they can. Strictly speaking, they should fit accurately, but practically it is difficult sometimes to get them right; in that case, they must be "humoured" to make the best of them. If plain glass be used, it is a much more simple matter to put it in, but a full $\frac{1}{4}$ in. all round must be allowed for "cover."

*Securing Photos.*—The method of fixing the photos in their places so that they may be readily and easily changed is an important one. In the bracket under consideration, three openings might be cut, $3\frac{1}{2}$ in. by 2 in., with a rebate behind each to allow the carte-de-visite to be placed in it. A thin sheet of clear glass in front would, of course, be requisite to protect the face of the photo, and a thin slip of wood, about 1 in. wide and $\frac{1}{8}$ in. thick, might be fitted tightly into the rebate behind the photo. This would keep the carte always in position, and it would not be a difficult matter to remove and change it. But another and a better way is that indicated in Fig. 1, where the three cartes are shown placed in a mount of some sort, which mount is then placed behind a sheet of glass inserted in the large opening, 10 in. by 5 in., prepared for it. The mount is made the same size as the rebate for the glass, into which it therefore fits closely, and behind it is placed a back, $\frac{1}{8}$ in. thick, with two movable cross-bars working on a centre pivot. These bars are made to project $\frac{1}{8}$ in. beyond the edge of the back, so that when the back is placed in the rebate behind the mount containing the photos, these cross-bars enter a little groove made for them in the frame. To facilitate the entrance, the bars are thinner at their extremities, as shown in Fig. 4, which is a section, full-size, of this part of the work. The black portion of this figure represents the glass; the white portion behind, the mount; the hatched portion behind that, the back; and the bar is shown outermost of all. In Fig. 5 is given a sketch of the back, showing the two cross-bars in the position they must assume to get it out and into its place. This is exactly the arrangement of movable back which is found in the common drawing-slate known to us all as children.

*Mounts.*—The "mount" containing the three photos must here get a few words to itself. It may be of cardboard, wood, silk, or other material. A cardboard mount is, perhaps, most easily made: a sheet of cardboard is made the exact size of the rebate, and has three openings cleanly cut in it to show the three cartes. This card may then be made like the leaf of a photographic album by means of other cardboard strips, covered with a sheet of stout paper all behind, which paper is cut to admit the carte being pushed up into its position—just as in an album. Or a simpler fashion is to glue a strip of cardboard of about the same thickness as the photo is round the exact position the photo is to assume, in order to keep it in its place. The back then put on behind it will keep it firm and fast. This mount may be made of wood—oak, mahogany, walnut, beech, chestnut, or any other wood—and left its natural colour, as when protected by the glass there is no danger of its becoming soiled. Little slips of thin wood must be fastened on behind this mount, as in the cardboard mount, to keep the cartes in position. Another way of finishing the mount is to cover it—either the cardboard or the wood one—with silk or plush of a delicate shade. A nice pale azure-blue or a pretty salmon colour would contrast nicely with the photographs, and with a white or a cream-coloured enamel on the woodwork. This must be left, however, to individual taste, as what would please one might not please another. Two little brass plates are shown on the top edge of Fig. 1; these are to fasten the shelf to the wall, and are screwed on at the back of the back board.

*Candle Sconces.*—The article sketched in Fig. 2 is of a different kind; it has no shelf, but has a pair of candle sconces attached. These may be had at various prices, from about 3s. per pair upwards, and they form a very great attraction both by day-light and by candle-light. The mirror between them catches and reflects their light, and the photos above could not be in a better position for being seen to advantage. This figure is also drawn one-eighth full size, and is made out of one piece of wood. A suggestion might be made as to placing a cabinet photograph where the mirror is, making the opening to suit; but unless specially desired to be so made, the mirror ought to have the preference.

Another arrangement is given in Fig. 6, where a cabinet photograph is placed on each side of a mirror, and a shelf is attached. This might be made with the back board, $\frac{5}{8}$ in. thick, all in one piece, but it would be better to form it with top and bottom rails half-checked into the side rails, and the centre divisions half-checked into top and bottom rails, and placed into them from behind. Before half checking them, the rebates round all the openings should be run. The shelf, 19 in. long by 5 in. broad, and $\frac{1}{2}$ in. thick, is supported on two brackets, also $\frac{1}{2}$ in. thick. The glass and photos are placed in position, as already described in connection with the first of these articles (Fig. 1). This also is drawn one-eighth full size.

A shelf with accommodation for five carte-de-visites is shown in Fig. 7, to the same scale as before. This is, however, shown of different construction; two posts, $1\frac{1}{2}$ in. square, with turned knobs at their lower ends, have a rail at top and bottom mortised into them, and underneath the bottom rail is placed a shaped piece of wood $\frac{1}{2}$ in. thick. The posts and rails are rebated to receive mount, glass, and back board as before. Above is placed a shelf $4\frac{1}{2}$ in. wide, which is supported with two brackets placed on the face of the posts. Both these and the shelf are $\frac{1}{2}$ in. thick, as well as the back ledge put on above all. The wall-plates should, for sake of strength, be placed, in this instance, on the posts underneath the shelf.

A more elaborate shelf is given in Fig. 8. It is framed together in the same manner as that last described, and is drawn to the same scale. Two cabinet photos are shown above the glass, which is dome shaped on top. The shelf, $\frac{1}{2}$ in. thick, is 4 in. wide at each end, curving out to 6 in. wide in the centre. A row of turned spindles under the shelf adds considerably to the general effect. A full-sized section of the post, showing it beaded and checked, or rebated, for the glass, etc., is given in Fig. 9.

Another simple little shelf, formed in the same manner as those just mentioned, is sketched in Fig. 10, while in the next figure is shown a larger one. This has a double shelf above the two cabinet photos shown, and is surmounted with a balustrade. The two posts enclosing the portraits are carried up to the topmost shelf, which should be checked to allow them to reach the top of the shelf. The wall-plates should be fastened to the tops of these posts. The four turned pillars at the corners of the shelves keep them equally apart, while the brackets underneath sustain them under any weight they may be called on to bear. The shelves are 21 in. long by 6 in. broad, and are $9\frac{1}{4}$ in. apart. The posts are 1 in. square, and rails $\frac{3}{4}$ in. broad and 1 in. thick. The turned pillars are 1 in. thick, and the spindles are $\frac{5}{8}$ in. at their thickest part, and 2 in. long over the shoulders, the pins at each end for fixing to shelf and spindle rail being beyond.

*Medicine Cupboards.*—A handy little medicine cupboard is shown in Fig. 12, drawn nearly one-eighth full size. The gables are 6 in. wide. As, however, the doors should be made to suit the size of photo used, they shall first receive our attention. A moulded rail is formed as in Figs. 14, 15, or 16, these being all alternatives for the same purpose, and are drawn full size for the sake of clearness. This rail is mitred together exactly like a picture-frame, and has the glass, mount, and movable back put in as before described. The gables are held together by the top and bottom of cupboard being dovetail-raggled into them, as shown in Fig. 17, also drawn full size, showing the gables and shelves to be $\frac{5}{8}$ in. thick. A shelf 4 in. broad should also be raggled into the gables, about half-way between the top and bottom of cupboard. A shaped spandrel is fixed under front edge of cupboard, while the back ledge at top and bottom is also shaped as seen in Fig. 12. This back is $\frac{3}{8}$ in. thick, and is set into the gables as shown in section in Fig. 18. The doors must have something to stop against when closing. A little stop is inserted in top and bottom of cupboard inside the doors, so that they may close against something solid. A sketch of this stop is given in Fig. 19, full size; in this sketch the dotted line shows the extent the stop is inserted into the wood, and it should be so placed that both doors will get the benefit—*i.e.*, immediately behind where the two doors meet. A little slip-bolt will be required on the left-hand door, and a lock on the right-hand one.

The remaining illustration (Fig. 13) shows another arrangement of a medicine cupboard. It has only one door, however, and at each side is a corner shelf for the accommodation of a vase or other article of vertu. The construction of this cupboard is very much similar to the former one, with the addition of the side brackets and shelf. Another plan would be to frame the back with the side shapings, and top and bottom rails, with a panel grooved into them, and the gables top and bottom of cupboard placed against this back. The door, of course, is formed in the same manner as the others, any of the sections given in Figs. 14, 15, and 16 being alike suitable.

*Conclusion.*—Amongst the many ingenious arrangements that have been made for keeping and displaying photographs, this idea of utilising them as decoration for useful articles, differing so much from the usual methods of storing our friends' counterfeits, will probably long retain its hold on the public taste. It is, of course, impossible to sketch all—or anything like all—the different forms and combinations which may be assumed; those given must suffice, leaving the ingenious reader to follow up—if he will—the lines placed before him in these pages.

## THE SAFETY BICYCLE: ITS PRACTICAL CONSTRUCTION, ETC.

BY A. S. P.

ENAMELLING, ENAMELLING STOVE—NICKEL-PLATED PARTS—RUBBER TIRES, CEMENT, METHOD OF FIXING—WIRED TIRES REQUIRING NO CEMENT—SPLICING TIRES—FITTING MACHINE TOGETHER AND TESTING BEFORE ENAMELLING—RE-FITTING UP—ACCESSORIES.

HAVING got our wheels and frame ready for the enameller and plater, the remaining work after these processes have been gone through is the fixing on the rubber tires and the fitting of the machine together. As to enamelling, the machine may be enamelled by baking in a stove, or it may be enamelled with a brush; the former is, however, by a long way the best: indeed, all good work is stove-enamelled. But for the mechanic making his own machine, the fitting up or providing of an enamelling stove is out of the question. It is a concern that costs £9 or £10, so if his machine is to be made a good job it must be sent out to a practical enameller, who will do it at from 15s. to 20s.; lining, if wanted, a few shillings extra. If it is to be done in the stove, it must be done before the tires are put on the wheels; if with a brush, the tires may be on or not, at option. For an enamel, or japan, to put on with a brush, I would recommend the Club hard-drying black enamel, which is sold by the Silico Enamel Co., and at most cycle shops. It is the best I have tried, and dries in a few minutes; for this reason it is somewhat difficult to apply, one part being dry before another is coated. It should be put on with a brush about an inch broad, covering a good bit of surface with a stroke of the brush. Two coats will be required on all parts that have been polished bright, so the whole may have two coats with advantage. It is to be understood, however, that this brushing process will not give results at all to equal stove work. It is only a substitute for the real thing, and is only used by makers on a cheap trashy class of machines. All the parts to be plated are, of course, removed from the frame before enamelling.

The plated parts of our machine comprise the following (although it is a matter of choice which to plate and which to enamel): handle-bar with its extension tube, brake-lever with the brake-rod (B, Fig. 35), lamp-bracket (Fig. 33), cone collar (Fig. 38), seat-pin (Fig. 30), the wheel hubs before wheels are built, cranks, pedals, bottom ball-bearings, pedal shaft, brake-spoon pin (Fig. 34), adjusting screws (Fig. 40), and all bolts and nuts about the machine. For Figs., see page 436.

We now give our attention to the tires, which are attached to the wheels after they have undergone the enamelling process. Our wheels are 30 in. by ¾ in. ordinary crescent; we therefore require two tires of these sizes, and I should here advise the procuring good rubber, somewhat about 4s. 6d. or 5s. per pound, as such tires are cheapest in the long run. The rubber may be either red or grey, so long as it is of good quality. Our tires are fixed on the rims with a cement made for the purpose, and sold at 1s. and upwards per pound, according to quality. Having thoroughly cleaned the rim, place the tire on it without the cement, in order to see if it requires stretching; because if it requires stretching it must be pulled equally all round the wheel, else you will have thick parts and thin parts, making a lumpy wheel.

Having melted the cement over a fire or a gas-jet, using an iron ladle with a spout for pouring (Fig. 43), have the wheel mounted on a spindle caught in the vice or driven into a post, then with a red-hot ⅝ in. iron rod heat up the rim all round by revolving the wheel; this done, pour the cement from the ladle, which, if properly melted, will be as thin as hot glue, and will run freely in an even stream all round the wheel, the ladle being held stationary and the wheel turned slowly with the left hand. Now place the tire in position before the cement is allowed to cool, and give it the necessary stretching, if any, taking care to place it in the rim without twist. There is generally a little ridge on the extreme top of the rubber tire, left there in the process of moulding: this ridge forms a good guide for placing the tire evenly in the rim. We now requisition a tire heater (Fig. 41): in this case a gas tire heater. The curved top piece of this instrument is perforated, and emits a number of gas-jets, the gas being led up through the shank from the rubber tube, said tube being attached to an ordinary gas-bracket with the burner removed. These heaters are made with the jet-tube from three or four inches up to nine or ten inches long; five or six inches is quite long enough. The rim is heated on the under side at the spokes with this instrument, the rubber tire being worked gently sideways with the fingers; the heater re-dissolves the cement in the rim, and when that takes place the tire rolls freely and the cement oozes out at the edges of the rim. This is continued all round the wheel, about ten minutes being sufficient for the purpose. See that the rubber is without lumpiness when setting it in the re-dissolved cement, as any flat parts can be easily remedied by pressing the tire from both sides towards it while the cement is hot. If too much cement has been put into the rim from the ladle, it will ooze out too much and smear both rim and rubber tire, making the latter (as it will not come off clean) very unsightly; there should only be as much cement in the rim as will make the rubber float when it is re-heated. If a tire is put on in the way I have described above it is sure to stay on, assuming that the cement is good. All that is required in fixing a tire is to make a proper union between the steel rim and the cement and between the latter and the rubber; the cement, if of a good quality, has the property of adhering to both these substances, iron and rubber, with great tenacity. The part the workman plays is to complete the union in a proper manner between them.

I have handled a lot of wheels made by a well-known firm, in which their method of enamelling is to dip the wheel, minus the tire, in a vat of stoving enamel, then to bake it in the stove. The result of this is that the hollow rim that is to receive the tire is enamelled the same as the other parts of the wheel, and on this enamelled surface the cement does not hold as on the clean metal. Their method of putting on the tire seems to be to heat up the rim, pour a light stream of thin cement, and to place the tire on, pressing it all round, and dispensing with the re-heating process, the result being that only a partial adhesion has taken place, the cement cooling too quickly to allow of a proper union with the tire, and which only re-heating will effect properly. I have had wheels treated in this way for tire fixing, where not a particle of the cement had found adhesion with the rubber; you could push the rubber out of the rim with the thumb without difficulty, and when removed half round the wheel the remainder would peel off by its own weight, and this on a machine costing about £18.

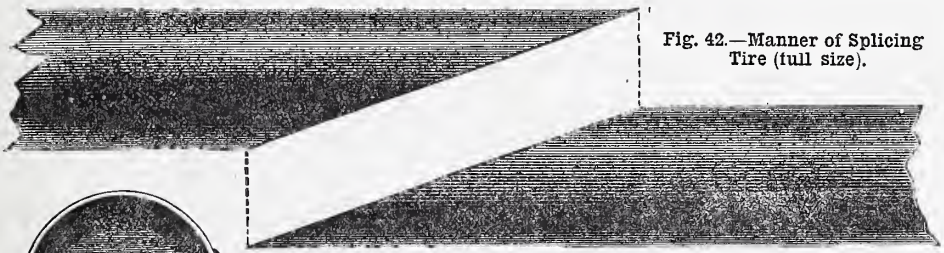

Fig. 42.—Manner of Splicing Tire (full size).

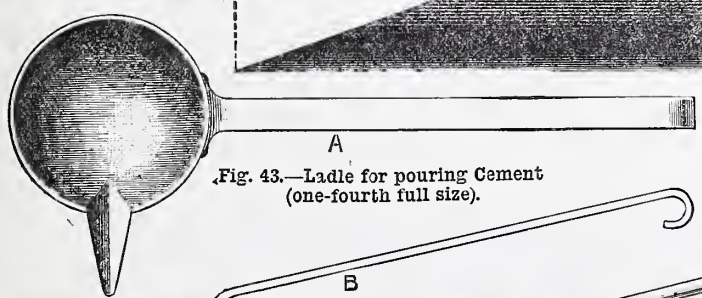

Fig. 43.—Ladle for pouring Cement (one-fourth full size).

Fig. 41.—Gas Tire Heater (one-fourth full size).

I would advise, therefore, a careful re-heating, with the jets not too large, in case of damaging the enamelled rim; or if the wheels are to be done with the brush, I would advise that the rubber tires be fixed in their places before painting.

It may be mentioned that there are tires in the market that require no cement; they are fixed in the rim by a wire passing through their centre as a core; it is pulled by screwing at the wire ends which are fastened to the rim. I have not seen them, so cannot speak of their advantages, or otherwise, from experience. There are tires also that require no cement, on account of the formation of the rim, but of these I need not speak further. I believe the best thing yet is the good old method of fixing by cement, and where it fails of its purpose it is the inevitable result of defective workmanship.

One method of making rubber tires is to mould them in long, straight lengths, then to make them to fit size of wheel by splicing. This splice sometimes gives way and has got to be repaired. A good solution for

this purpose is sold in most of the cycle shops.

A tire too large for a wheel, or a tire to be adapted to a smaller wheel, has to be cut and re-joined. It is done by splicing in the same way. The method of doing this is shown in Fig. 42. A clean cut with a sharp thin knife dipped in water is made slanting as shown, the cut being about two inches long; this cut is made on both ends of the rubber, and both from the upper or outer side of the rubber, so that one side of the splice will lie embedded in the cement. Both cuts must be exactly the same length, and made straight and smooth; these cuts are smeared with the solution above referred to, and the tire laid aside *before joining* for an hour or more; after that time the two splays are laid carefully together and pressed with the fingers; they may then be beaten with a bit of wood, when the joint will be found to adhere so that you could not pull it asunder, and you may proceed at once to fit it on the rim, and to use it on the road immediately.

The solution referred to is sold in one shilling bottles. Accidental cuts in tires may be repaired with it by cleaning out the parts carefully and smearing them with the solution, after which they may be kept open for an hour or so, when they may be pressed close, and the wheel is then ready for use without further waiting.

After the tires have been set in the rims and put aside for an hour or two, all superfluous cement must be cleaned off; it will come much more readily off an enamelled surface than off the rubber; allowing it to get on to the rubber should therefore be avoided as much as possible.

Now I will assume that you have got your frame and wheels done nicely in an enamelling stove, and the other parts enumerated in this chapter well plated, and that you have put on the tires as above directed. What remains now is to fit the whole together to complete the job. Having had the whole job fitted up complete before it went out to the enameller, you will have no difficulty in the re-fitting. At this point I would impress upon anyone making his own cycle the necessity of fitting up his machine complete, every item in its place, and testing the whole before it goes out to enamel; he should see that his two wheels are running in line with each other, so that when running straight they will make but one track; he should see that all moving parts move freely, such as brake and handle-bar adjustment, seat-pin adjustment, etc. etc., that all set-screws and bolts are performing their work effectually, that no nuts are made too easy in the threads, and therefore liable to drop off; he should also mark all parts that go in pairs, so that he will know how to replace them at the final fitting up: such, for instance, as the ball-bearings in the bottom brackets, cranks, pedals, etc. He should lift his rear wheel off the ground and drive it at great speed, to see that the chain runs freely, does not threaten to come off, and does not make any undue noise. Then, if he has facilities, he should further test his machine by getting on to it, or getting a rider on to it, and running in circles and figure 8 on a floor or a smooth clean court, so as not to damage the tires. This operation will discover any cracks, flaws, or other defects, which should by all means be cured before going to be enamelled. If it passes through this ordeal without sign of failure in any part, then the maker may congratulate himself on having done a creditable bit of work.

I will assume that the cycle builder has done all this, and that the enameller and plater have satisfied him with their part of the work, and that he has everything ready to re-fit up: this, I assure him, will be the most agreeable part of the whole task. But as this paper is about long enough, I will leave him till my next and concluding paper of this series, in which I will assist him in this pleasing operation, and show, by illustration, his machine completed and fully equipped for the road, and which I hope will be to him a thing of beauty, and if not a joy for ever, at least for a long time to come.

The accessories not mentioned in these papers, and that are necessary to equip the machine, are lamp, bell or horn, tool-bag, spanner, and oil-can. These I will notice shortly in my next, which will conclude with a few hints to the mechanical cyclist how to take care of his machine: such hints being intended for the benefit of cycle owners and users generally, and apart from own cycle builder, and which, it is hoped, will be duly appreciated by them.

## OUR GUIDE TO GOOD THINGS.

*** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of* WORK *for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of* WORK *without charge, the notices given partake in no way of the nature of advertisements.*

### 78.—The City Polytechnic.

Having called attention in the last number of Work to the classes for the study of wood carving at King's College by the united action of the Carpenters' Company and the authorities of King's College, I must do the same in behalf of the City of London College, White Street, Moorfields, E.C., otherwise known as the City Polytechnic, in union with the Society of Arts, the Government Department of Science and Art, and the City and Guilds of London Technical Institute, whose forty-fourth annual session for 1891-92 is now in progress. Lectures and lessons are given in technical drawing and drawing office practice, building construction, machine construction, civil and mechanical engineering, quantity surveying and land surveying. Application for further information with reference to terms, fees, etc., should be made to Mr. David Savage, the Secretary, at the College. The principal lecturer is Mr. Henry Adams, M.Inst.C.E., M.I.Mech.E., F.S.I., etc., assisted by Mr. A. B. Hoskin, science teacher.

### 79.—Goldsmiths' and Jewellers' Trade Classes.

A contributor to Work, Mr. H. S. Goldsmith, who has taken up and successfully dealt with two branches of goldsmiths' work in his papers on Brooches and Earrings, calls attention to the fact that, for the first time in London, a course of lectures, amounting to about thirty in number, on goldsmiths' work and the manufacture of personal ornaments will be given by Mr. Harry Stapleton on Friday evenings from 8.30 to 9.30 p.m. at the Polytechnic Young Men's Christian Institute, Regent Street, W. Only those who are engaged in the goldsmith or jewellery trades will be eligible to attend the lectures. The classes, I believe, will have started before this number of Work appears. It may be useful to add that the instruction afforded will embrace the following: (1) The principles and methods of manufacturing the various kinds and styles of personal jewellery; the exhibition and description of the tools generally used; the simpler gold alloys and their solders, together with the various methods adopted in finishing gold work. (2) Special lectures will also be given dealing with the subjects of chasing, engraving, and enamelling: special classes being also held for designing and chasing, as applied to goldsmiths' and jewellers' work. (3) Other information than that which may come under the foregoing heads, likely to be of special advantage to all engaged in the various branches of the trade, will also be included.

### 80.—"Cyclist and Pedestrian Guide to the Neighbourhood of Dublin."

This guide, which has been prepared and produced by a cyclist well known on both sides of St. George's Channel as one who can hold his own when in thorough condition, both for long and short distances, against all comers—Mr. R. J. Mecredy—appears to be a model book for the purpose for which it is intended, and might well be imitated in the production of similar volumes for various parts of England and Wales and Scotland. The plan of the book is simple but useful. Descriptive matter relative to any particular place, and the means of reaching it, are given in the centre of the page, and then, as marginal notes on the left hand, are the successive distances from one place to another mentioned in the route until the destination is reached, and on the right hand the condition of the roads. First of all, all the various exits from Dublin are dealt with, with some noteworthy runs. Then follow straight-away and circular rides from the General Post Office, Dublin. The book is well illustrated by cuts, and is rendered still more complete by an excellent index, in four columns, of which the first contains the name of the place; the second, the direct route; the third, reference to page; and the fourth, the distance in miles and yards. No cyclist resident in Dublin, or visiting Dublin, should be without this exhaustive and well-arranged volume.

### 81.—Pictorial Astronomy for General Readers.

Messrs. Whittaker & Co. have added to their Library of Popular Science a volume entitled "Pictorial Astronomy for General Readers," by George F. Chambers, F.R.A.S., of the Inner Temple, barrister-at-law, the author of various legal and scientific works, among which is the "Handbook of Descriptive and Practical Astronomy," produced at the Clarendon Press, Oxford, in three volumes. Of course, the volume now under consideration is an inexpensive book of moderate compass, and is based, to a limited extent, on Hinds' "Illustrated London Astronomy," which appeared some forty years ago, but is now out of print, and whose illustrations have consequently been utilised for Mr. Chambers' book. The mode of treatment will perhaps be best understood from a short summary of the subjects of the successive chapters, and which, after the preliminary introduction in explanation of the various branches of the subject which are embraced under the general term "Astronomy," deal with the solar system, the sun, the inferior planets, the earth and the various phenomena connected therewith, the moon, the superior planets, eclipses, transits, and occultations, comets, meteors, the stars, clusters and nebulæ, telescopes, the spectroscope, the history of astronomy, the utility of astronomy, tables of the planets and satellites, and a catalogue of celestial objects. A sufficient index completes a book that is well and succinctly written, and being in simple language, is as well calculated for the use of the young as those of riper age.

### 82.—Finsbury School of Practical Amateur Mechanics.

I am requested to state that the classes for Cabinet Work and Carpentry, Wood Carving and Engraving, Wood Turning, Metal Working, and Mechanical Drawing, carried on under the superintendence of the Principal, are now in active operation. The Editor.

# SHOP:

## A Corner for Those who Want to Talk It.

*** *In consequence of the great pressure upon the "Shop" columns of* Work, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—Letters from Correspondents.

**Answers by Post.**—Correspondents generally are requested to bear in mind that no letters with reference to subjects treated in "Shop" can be answered by post, and that in future the Editor will decline to forward sealed letters addressed to writers in "Shop" under initials or pseudonym. This has been rendered necessary by the following letter, recently received from a member of my staff:—"Parties have been writing, wishing me to answer their questions by letter, and not through Work, offering to pay me well for doing so. But as I wish to act honourably both towards you and towards the readers of Work, I ask you to again give correspondents to understand that all questions sent to Work are to be answered through the 'Shop' columns."—Ed.

**Notes on Hand Saws.**—Chopstick writes:—"Having read the article by M. Powis Bale on p. 421, I cannot resist the temptation to write a short criticism of the same, and I will state, at the beginning, that I am speaking from practice, while Mr. Bale is quite evidently speaking from theory alone. First, as to the form of teeth most suitable for different kinds of work. These most decidedly are for a hand saw, which everyone in the trade will know is meant for cutting across the grain only; the form shown in the article at Fig. 1 is the best. For a rip saw, that shown in Fig. 2. As to Fig. 3, it is most unsuitable for a hand saw of any kind, but is the right shape for a cross-cut for cutting logs, but for which is recommended the ridiculous shape shown in Fig. 7. Now as to the size of the teeth. For a hand saw, five teeth to the inch, and for a rip saw, three to the inch, is the best. And now a word or two as to sharpening and setting. The latter should be done first, and I advise everyone to stick to the old-fashioned set, and discard all patent spring delusions. With this and a proper taper saw file (a 4½ in. for a hand saw, and a 6 in. for a rip saw) I can, and so can everyone else if he tries, sharpen a saw so that it will cut any and every kind of wood, which is what is wanted, unless we can afford a separate saw for every kind of wood. In sharpening (after the setting is done, mind), keep the teeth of uniform size, all the same level, and your saw will work clean and easy. A good test is to hold the saw teeth upwards, with the point resting on the bench and the handle about a foot higher, then place a needle on the teeth at the highest point, and it should run to the bottom without falling off. I can sharpen a saw so that it will do so; can the author of the paper? I will guarantee that he cannot, or he would know more of the subject upon which he wrote. One more point I must touch upon, and I have done. It says: 'That for straight-grained wood the square tooth answers fairly well, but for cross-grained the tooth requires to be bevelled.' Now, the fact is just the opposite, which anyone can prove by a trial, though this is much more apparent in machine saws than in hand saws; but the fact is the same, nevertheless. I am sorry to take up space in this way, but I think that we practical men should have our say, as well as those who speak from theory only. The latter is a good thing, no doubt, but practice will stand on its merits, in certain cases, far better."

**Sheet Metal Work.**—Tinker writes:—"As a reader of Work from the first number, I read with great pleasure the articles on sheet metal work, and also the replies of Mr. Alexander in 'Shop,' as they are always very concise and to the point. But the best of us make a slip sometimes, and there are one or two little slips that I am sure were not intentional, and which I will point out. In Vol. III., No. 120, p. 252, in answer to Blacksmith, *re* oil-bottles, R. A. gives the size of a 2 quart bottle as 19½ in. by 6¾ in.; but that size when made up would hold nearer 3 quarts than 2 quarts. The size to cut a 2 quart oil-bottle is half a double plate, or 17 in. by 6½ in. As I happened to be on a gross at the time, I measured one, and found it held the best part of half a pint over the 2 quarts. There is also a slight slip or two in R. A.'s last paper on 'Oval and Cylindrical Vessels in Sheet Metal Work.' In No. 127, p. 359, in explaining the way to cut the rim for an oval kettle (and it is the correct way), the process explained is all right, but the drawing is wrong (Fig. 12), as there are no straight pieces in the drawing, but all flue, which would convey an opposite impression to the description of the cutting-out of the rim. Also in the bottom line of the middle column, p. 359, R. A. says, 'middle plate cut in two pieces, 17 in. by 17½ in.,' which should be 15 in. by 15½ in. In conclusion, I hope Mr. Alexander will take these little corrections in a right spirit, as I am sure there is nothing comes from him (or any other contributor) but what he honestly believes to be correct, and no doubt he, as I should myself, takes great pleasure in giving others that are not so competent, every possible practical help."

**Notes on Hand Saws.**—A. R. (*Scorrier*) writes:—"Whenever I see an article on saws, sawing, or on wood-working machinery of any description, it attracts my special attention. Now, one man's opinion may vastly differ from another's practical experience on the same subject. In No. 131, p. 421 of Work, M. Powis Bale gives his opinion in reference to hand-saw teeth. As the object of Work is to enlighten its readers, I venture to write as follows, but with due respect to M. Powis Bale: Figs. 1, 2, and 3, on p. 421, represent hand rip saw teeth, of which M. Powis Bale says Fig. 1 is undoubtedly the worst form. Herein I disagree with M. Powis Bale. I will allow that there should be a little more rake than represented in Fig. 1, but not near as much rake as in Figs. 2 and 3, which M. Powis Bale claims to be the better form. I do not hesitate to say that if any man tried to work a hand saw with rake in teeth as represented on p. 421, Figs. 2 and 3, that he found a difficulty in working it, and that if he persisted in working it that his saw soon became buckled. If the readers of Work have followed the articles by M. Powis Bale on saws, they might have noticed the following statement that the teeth of a circular saw driven by steam-power can be worked with more rake than a vertical or frame saw, because it is driven at a high speed. I suppose there are but few men that have had greater experience in sharpening of circular saws than myself, and the rake represented in Figs. 2 and 3, p. 421, for a saw to be worked by hand, is more than I should give in teeth of a circular saw for general work driven by steam-power. In reference to teeth, Fig. 7, p. 421, I can say nothing of its merits or demerits in reference to its cutting qualities. I believe it is generally understood that the ordinary teeth in two-handle cross-cut saws, if the angles are suitable for the work it has to do, are best. There are many forms of teeth claimed to be of American origin, but even in that country the ordinary teeth are principally used. I might give several reasons why the ordinary tooth is preferred. Again, I might write in reference to the M shape tooth (Fig. 6, p. 421), proving that the general hand-saw tooth is preferred, but defer writing until a future occasion."

**Testing Accuracy of Framework.**—G. P. (*Elgin*) writes:—"With reference to a communication from J. C. K. (*London, N.W.*), headed 'Testing the Accuracy of Framework' (p. 427), I am exceedingly surprised to see such an erroneous statement made by one usually so accurate as he is. He writes with the intention of showing that the method of testing the accuracy of framework described in p. 326 is incorrect, but only succeeds in showing that the diagonals of a trapezium *may* be equal. Now, Mr. Scott refers to picture-frames and other rectangular objects, namely, objects which have their opposite sides parallel, and their angles right angles. But objects which have their opposite sides parallel have their opposite sides equal; and, therefore, picture-frames must have their opposite sides equal. Now, all

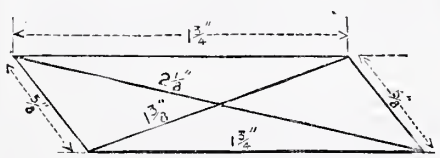

Fig. 1

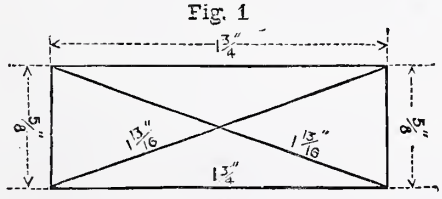

Fig. 2

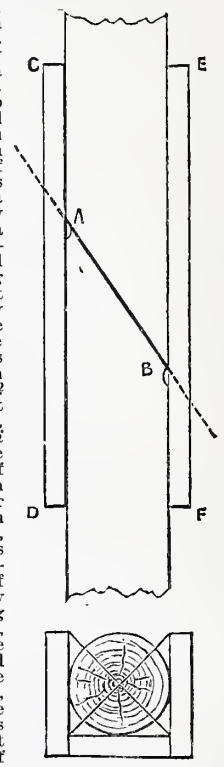
Diagrams showing how to test Framework.

picture-frame makers that I have ever seen take great care, when making a frame, to make the opposite sides of it equal. They first make the moulding for one side the required length, and then they adjust the moulding for the opposite side until it is exactly the same size. Again, if a figure have its opposite sides equal, but its diagonals unequal, the angles will not be right angles. (Fig. 1.) But if a figure have its opposite sides equal and its diagonals equal, then its angles are bound to be right angles. (Fig. 2.) This can be proved with the aid of Euclid, Book I., as follows: ∠ B A C = ∠ D C A (I. 8). ∴ A B is parallel to D C (I. 27), and A B = C D. ∴ A D is parallel to B C (I. 33). ∴ A B C D is a parallelogram. Now ∠ A D C = ∠ B C D (I. 8). ∴ ∠ A D C = ½ ∠ A D C + ½ ∠ B C D. But ∠ A D C + ∠ B C D = 2 rt. angles (I. 29) ∴ ∠ A D C = 1 rt. ∠; ∴ ∠s D A B, A B C, and B C D are each equal to 1 rt. ∠. I hardly think that J. C. K. will now protest against this method of testing the accuracy of framework, since it is proved here on the strength of information which has been handed down to us from the time of Euclid, about 300 B.C., and the accuracy of which is of such a high standard of excellence that no one has been able to dispute it through all these centuries."

### II.—Questions Answered by Editor and Staff.

**Splicing a Mast.**—Nauticus.—I am not clear as to whether Nauticus wants to know how to make a "ship's splice," or other method of joining the parts of a mast together, or whether he merely wishes to know how to "scarf" together two pieces of round timber. As the latter method is probably what he requires, I will describe it, merely premising that if correspondents would only state clearly and fully what they wish to know, they would get much more satisfactory replies. Nauticus's difficulty seems to be to draw a straight line over a round. A mast-maker would do this by making a small groove or nick on each side of the mast, as shown at A and B, into each of which a small batten is fixed. With these as a guide, it is easy to draw the line required with a straight-edge.—L. L. H.—[Thus far, my good friend L. L. H.; but supposing that it is the scarfing that Nauticus is in difficulty about rather than the splicing or binding the scarfed ends with cord, is it not possible to help him a little more effectually? I think so myself, and that it may be done in this way, and the *modus operandi* shown by adding a little to L. L. H.'s drawing. If Nauticus made a wooden trough after the manner of a mitre-box, shown in plan by the steps C D, E F, on each side of L. L. H.'s mast, and in section below, and cut a saw kerf in each step as shown by the dotted lines extending from A and B outwards, taking care that they are truly vertical, he would then, after dropping the pole into the mitre-box, be able to saw each piece across at the same angles to form the scarf without any trouble whatever. If the mast lies too loosely in the box, the pole should be steadied by a small wedge, care being taken to wedge each piece on the same side.—Ed.]



Scarfing a Mast shown in Plan and Section.

**Printing Type.**—W. G. C. (*Sierra Leone*).—Small founts of type are made up and sold by Squintani & Co., Farringdon Street, E.C. Possibly the rubber-faced type made and sold by Richford and Co., Snow Hill, E.C., might suit you better than the ordinary kind.—D. A.

**Writing Desk.**—A. C. (*Blackfriars*).—Your desk being made of wood ¾ in. thick, and having a margin of only ⅜ in. around the fretted part, I am afraid you will find the difficulty of fastening by dovetails greater than you can get over. It might be done with great care, but would require skilful hands, as there is only ¼ in. to spare after cutting the sockets. The mitred dovetail would be the neatest and strongest joint in your case, but I can hardly advise you to try it on such delicate work unless you have made it on a larger scale. You might fasten the parts together with screws, but that would not be at all a workman-like plan. The best method for you to adopt will be to mitre the corners. This will prevent end grain being seen, and in appearance will be the same as the mitred dovetailed joint. The strength of a plain mitre, even with glue, will, however, not be sufficient, and must be increased either by keying or blocking. To key the parts together, after having glued them, take a small saw, such as a dovetail saw; cut diagonally from the corners in, say, two places in each. Into each cut then glue a piece of veneer, and when the glue has set, trim off the surplus projecting veneer. This makes a strong joint when properly done. Blocking is easier, and is done by just gluing strips of wood to the inner angles of the desk. I do not know in what way you intend to support or back up the tret. It will be very apt to get broken unless you do something of the kind, as I strongly recommend you to. If you do, then make a box of thin wood, and overlay the fretted parts outside it. The joints of the inner box can be made as strong as you like, while those on the frets can be simply mitred, as the frets will be stuck on with glue.—D. D.

**Fine Cutting (Picture-frame Cutting).**—If you want to make a fine cut, of course you must use a fine saw. Of course, I am supposing you are possessed of the necessary skill. You cannot do better

than get one of the Britannia Co.'s circular saw benches.—D. A.

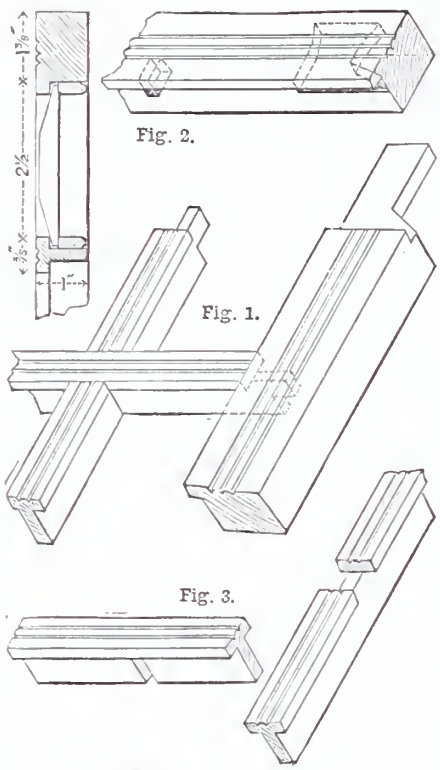
**Old Hall-marks.**—C. F. (*South Shields*).—If you want the very best books on this subject you will have to get "Hall-marks on Gold and Silver Plate," 6th edition, by W. Chaffers, published at 16s. by Reeves & Turner, 196, Strand, London, W.; or, "Old English Plate," by Wilfrid Joseph Cripps, M.A., F.S.A., published by John Murray, Albemarle Street, at about the same price as the other. Personally, I prefer the "Old English Plate;" it is more readable, and better illustrated. In these books will be found tables of

Old Hall-marks.

date letters used in the assay offices of the United Kingdom, with an account of French marks, and many German, Belgian, and Dutch ones; in fact, they are as complete as it is possible to make them, and they are well worth the price they are published at. After these works, the next best is one of the excellent South Kensington Museum handbooks on "Gold and Silversmiths' Work;" it is published at 1s. in a paper cover, 1s. 6d. in cloth, and is printed for the Science and Art Department, South Kensington, to whom application should be made. In that book the matter is very shortly dealt with, and merely the first letter of each cycle of twenty years is given. One alphabet is used in regular order—from A to V, omitting J and U or V; that, of course, will make the number to twenty letters, instead of twenty-six. As neither of these books may be easily got at, I give the first letters and the shields from the cycle beginning 1678-9 up to the present time, the present letter being Q. For details of the first introduction of letters for the makers' mark instead of a symbol, and for several other matters, the shilling book will be found useful; but the others are the ones to possess.—H. S. G.

**Sleepers.**—CARPENTER (*Durban, Natal*).—In reply to your query only an approximate answer can be given, as the statistics, if obtainable at all from the companies, could only be got with considerable delay. The sleepers on nearly all the lines in Great Britain are placed transversely, with the exception of the Great Western, where the continuous sleeper is in use. There will be in these, together with the transverse pieces for keeping the gauge, almost the same amount of timber as there is in the transverse sleepers of the regular gauge. I have, therefore, reckoned the amount of timber in the broad gauge as if the sleepers were laid transversely, as on the other lines; and as next May the B. G. will entirely disappear from this island of ours, I shall not be much out. The following paragraph, taken from "The Working and Management of an English Railway," by Findlay (of the London and North-Western Railway), one of the best authorities of the day on such subjects, will be useful to you:—"The improved form of permanent way actually in use upon the London and North-Western Railway at the present time. It consists of wooden sleepers laid transversely, and which are of well-seasoned Baltic timber, into which creosote oil has been forced under pressure to the extent of 3¾ gallons to each sleeper. The sleeper, which is 9 ft. long by 10 in. wide by 5 in. deep, when creosoted weighs 150 to 160 lbs. Each 30 ft. of rail rests on ten sleepers. A certain number of iron and steel sleepers have been laid down on the London and North-Western Railway experimentally, the first step having been taken eight years ago. The results have been varied, a percentage of the sleepers having failed, while, on the other hand, a larger percentage appear to be standing well." From the above it appears that the sleepers are 3 ft. apart, so, as this railway is under extremely good management, I shall consider this as the average pitch for the sleepers on all the railways in Great Britain, the sleepers on some lines being closer while on others they are wider apart. Now the number of miles of railway in Great Britain open for traffic at the present time is 16,114·75. Taking the sleepers at 3 ft. pitch, we obtain the grand total of 28,414,760 sleepers for a single line of rail. The life of a sleeper varies greatly and from several causes. Sleepers cut from the same kind of trees, grown on almost the same spot, vary very considerably; those cut from trees growing in the valley and damp ground standing much less wear and tear than those obtained from the same class of tree growing higher up on the hill or mountain side. Again, sleepers obtained from trees grown under precisely the same conditions vary as regards length of life, on account of the positions they occupy on the line, those most subject to alternations of moisture and dryness, and beat and cold, decaying much faster than those placed under more favourable conditions, especially as regards drainage. One of the most favourable conditions of a line, for lengthening the life of the sleepers, is to have it thoroughly well drained. The length of life again varies with the species of wood; oak, though too dear to be used in this country, lasts much longer than any other kind. From particulars obtained from a good authority, I find that a sleeper decays and is useless any time between three and twenty-five years, according to the above conditions; so I think if I take eight years as the average life I shall not be far wrong. If we now divide the total number of sleepers in use on our railways by 8, we shall obtain 3,551,845, or over 3½ millions yearly, as the number actually needed to replace the worn-out ones on a single line, but all railways in Great Britain have double lines, with the exception of a very small percentage which will be entirely counterbalanced by those lines which have four sets of lines, so that we must double the 3½ millions, when we obtain the great number of over 7 million sleepers needed yearly. This, of course, takes no account of the sleepers used in the miles of sidings. Baltic fir and similar classes of timber are almost universally used in Great Britain, and the method of preserving them by injecting creosote oil is the general method employed. The timber used comes from the Baltic provinces, Norway, Sweden, and America. The home forests would not supply the smallest fraction of the timber needed. Indeed, there are no forests here in your sense of the term.—P. B. H.

**Bookcase.**—S. C. (*Ashton-under-Lyne*).—I give you three sketches, showing how the doors are mortised, together with the measurements as far as I can. The height and width of your doors you must decide for yourself, as you alone know what



Mode of Mortising Doors of Bookcase.

size the bookcase is. Those referred to are about 2 ft. 6 in. wide, by 2 ft. 2 in. high out to out. Fig. 1 shows part of one top rail, style, and two bars. Fig. 2 is a section through one style and one bar, showing how the glass is fixed in, etc. Fig. 3 shows an easy way of making the joint where the bars meet. The fronts of the horizontal bars are housed out, and the backs of the vertical bars are notched out to pass over the part left on the horizontal bar. Any turner will do the turning required; it is a very simple job. You will not have any difficulty in getting the bevelled glass in Manchester; but as the glass is rather a serious item, I should advise you to make inquiries as to price at several glass merchants. If any other troubles crop up as you go along, let me know, and I shall have much pleasure in putting you right.—E. D.

**Bicycle Tires.**—W. H. F. (*Rye*).—If you have an invention that will prevent pneumatic tires being punctured, and that makes the tire independent of compressed air, then you have hit upon something that any of the makers of tires will be glad to hear about, as that is just what they have been as yet in vain trying to discover. Write to the Dunlop Pneumatic Tire Company, Dublin; or the Clincher Tire Company, Edinburgh. The firm mentioned by you is unknown to me. You could communicate with Brown Bros., 7, Great Eastern Street, a firm which I know to be reliable.—A. S. P.

**Stoving Enamel.**—W. W. (*Manchester*).—Stoving enamel can be had in two tins for first and second coats for about 1s. a tin. Time on stove, one hour at 300 degrees of heat. The tins are labelled to show which to apply first. The two tins sufficient for one bicycle.—A. S. P.

**Mounting Etchings.**—W. F. B. (*Rochester*).—Surely your own ideas of the fitness of things ought to be sufficient to tell you how to paste etchings, etc., in a book. The colour of the paper must depend entirely on the nature of the etching, drawing, or painting; white, cream, and grey would seem to be the most appropriate. It must depend on your own judgment entirely whether or not you surround them with lines disposed in the form of an Oxford frame.

**Lithographic Printing.**—A BEGINNER.—Papers on the "Art of Litbography" are now appearing in WORK, and will soon be completed; but up to the present time no articles have appeared on lithographic printing.

**Slimy Sponge.**—A BEGINNER.—Wash your sponge well in hot soda water with a little soap, then rinse it well in cold water, squeeze the water well out of it, and let it dry. This done, use it as a sponge with water only and not with soap, and squeeze the water well out of it before putting it again into the sponge dish.

**Mail Cart.**—A NEW READER.—You will find directions for building a mail cart in No. 30 of WORK, and a reply to a correspondent respecting mail-cart wheels in No. 51.

**Bicycles.**—F. S. (*Kidderminster*).—It is probably as well that you and your friends gave up solving the puzzle of the bicycle, and it would have saved some time, no doubt, if you had never attempted it, especially when it was plainly visible that the description had not been written by a man who was of a mechanical turn. To get you out of your difficulty I send sketches and a condensed description of the specification. What the inventor intends to gain by his arrangement I do not know, as the seat must be thrown very far back, and the ordinary chain driving seems to me far more mechanical and a great deal simpler. The condensed specification runs as follows:—"My improvement consists in contracting the hub so that the main driving spindle shall pass through the wheel and toothed hub revolving round the spindle. The spindle carries an internal toothed wheel, the teeth being semi-circular and gearing into similar teeth on the hub on one side of the wheel. I make a drum or hub of suitable size, D (Fig. 1), having teeth on the outside, T, into which drum I place a disc or cone, C, at each end. Fig. 2 shows a side elevation, with a few spokes and rim of wheel, the cones being joined together by a spindle, J, extending above and below crank, K, the said disc or cones being made suitable for ball bearings, now in general use. The said discs being eccentric, and having the hole bored near the edge, E, I place the driving spindle, S, in and through, the said spindle carrying an internal toothed gear wheel, G, so slipping into, or engaging, with the teeth on the drum, D; the said toothed gear wheel, G (Figs. 1 and 2), on the spindle exceeding the size of the one

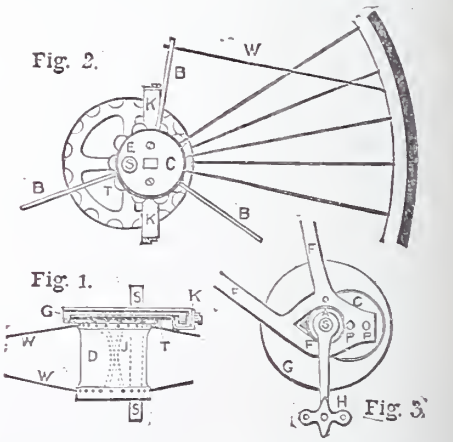


Fig. 1.—Plan. Fig. 2.—Side Elevation, Frame and Cranks removed. Fig. 3.—Side Elevation.

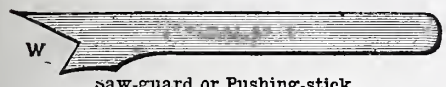
on the drum, or hub, D, according as the eccentric is placed out of the centre of the disc, C, aforesaid. The gear wheel would be placed in the space O, between the cranks, K, in Fig. 1; the double crank running round the gear wheel is placed on the outside. The gear wheel, drum, and wheel being complete, I secure them to the frame fork ends, F (Fig. 3), or angle arms, by pins, P, to the cones, C; the spindle moving in bearings, A, in or on the said fork ends of frame, H, the pedals, F, being movable on C to gear up." Some of the letters marked on the drawings are not explained in specification. The above is what appears in the specification, and, as I said before, where the improvement is, I can't see, but you will be able to see for yourself.—P. B. H.

**Guard.**—SAW-GUARD MAKER.—I know of no maker of a guard such as you require, and am of opinion that should such a guard be invented it would be a disadvantage, as in feeding timber to a circular saw the hands should be perfectly free. To be satisfied that there is no maker of such a guard, I wrote to one of the principal firms of wood-working machinery in England, and received the following reply:—

"DEAR SIR,—We have your favour of the 12th inst., but regret we are not acquainted with any guard suitable for the purpose you require, or we should be glad to give you the information desired."

In cutting thin, and especially short, stuff, we always use a pushing-stick in form of annexed sketch. The stick is from 12 in. to 15 in. long, and



Saw-guard or Pushing-stick.

when the saw is nearly through the cut, the stick, which is kept on the bench and near the right hand, is used by placing the end, W, against the piece of wood being sawn, and the piece is pushed to the saw without endangering the right hand. The left hand merely steadies the outside piece. In reference to your shield—not being able to cut above 10 in. deep with it—I suppose your bench is made to carry saws that will cut up to 10 in. deep, and your shield is made in accordance with it. Should you write Mr. Taylor, stating what you require, he may supply you with a shield suitable for larger saws. If I were near by so that I could see your bench, I might be able to suggest something. I might say that for the work you have to do, I would strongly recommend a band saw; you would find it a great advantage.—A. R.

**Cement.**—W. J. C. P. (*No Address*).—The query about a cement to resist "heat and moisture when applied to broken ware" is decidedly vague, and I was at the outset considerably puzzled by "the stitches which appear like lead on both sides." Anyhow, by a process of exhaustion, and by the noting down of things that W. J. C. P. seems not to mean, I have arrived at some sort of idea of what he does mean. As W. J. C. P. hails from Jersey, he probably means by "ware" the earthenware marmites such as are used for the preparation of bouillon; by "heat," when applied to broken ware, he probably means the fire; and by "moisture," the contents of the vessel which eventually will be served up as soup. This is all I can find in the query to go upon. The "stitches which appear like lead on both sides and do not show where or how the stitch is joined" are undoubtedly what are known to the initiated as rivets, and the leaden appearance is perhaps to be explained by the fact that the brass wire which was used for the rivets was tinned over to prevent any possible action of acid on the wire. As to this method of "stitching" broken ware, I cannot do better than refer W. J. C. P. (and so save my own time and space in WORK) to No. 53 of WORK—that is, page 4, Vol. II.—where he will find full instructions and diagrams of all the tools required. Now to go back to the cement question. It is not easy to give any advice without knowing what the ware is and where the crack or fracture lies. If a portion of the rim of a vessel is broken out, white-lead spread upon tape, and wrapped round the article, makes an almost unbreakable joint when thoroughly dry and hard, or, to keep up W. J. C. P.'s metaphor, will make a most serviceable kind of "patch" on the ware; this is assuming that the personal appearance of the ware after mending does not matter very much. Marble or alabaster, scraped into a fine powder and mixed up into a thin creamy paste with gum (the best and purest that can be got), make an excellent cement that will stand heat and a certain amount of moisture. It answers, to my personal knowledge, in positions such as the handle of a brown earthenware teapot, but I question whether it would stand the direct heat of a fire at all. I have heard, and read too somewhere or other, that if the outer discoloured portion of an oyster shell be removed, the white, flaky stuff inside, ground to flour and mixed with white of egg, forms an exceedingly good cement, and will withstand moisture and heat. In composition it, of course, resembles the one I have mentioned above. If the article W. J. C. P. wishes to mend is at all heavy, and it is to be lifted on and off the fire with any weight of liquid in it, I should advise him to rivet it in addition to any cement he may decide to use. This reply may seem long, but is mainly the fault of W. J. C. P.'s badly expressed query.—H. J. L., J. M.

**Inspectorship of Factory, etc.**—A FAITHFUL READER.—I regret that it is not in my power to tell you "the things required to obtain a situation as factory or workshop inspector, where to apply, and when examinations are held, if any."

**Tips.**—G. F. J. (*London, W.*).—I well know the difficulty there is in getting a good shape tip for London West-End bespoke work. I have made every inquiry, but failed to find a man. This answer will be read by a good many practical workers in iron and brass; it may prove of some use to you and many others. A good shape being one of the greatest drawbacks to the production of good tips by men not acquainted with the boot trade, I will undertake to give, free of charge, to any workman (the Editor has my address), paper patterns, or drawings, of good and fashionable-shaped heels, and hints as to what is really wanted. It is a long-felt want that has never been supplied, and having suffered under it myself, I am willing to do all I can in the matter. It is a good opening for some energetic reader of WORK.—W. G.

**Pack Sheeting.**—R. S. (*Darwen*).—It will depend a good deal on the quality of the wrappers whether you could treat and utilise them as floor-cloth. They might be made available for the purpose, but I am afraid you would find in the end that they would cost you far more than if you were to buy the floor-cloth ready. If you want to use them up in this way, try painting them with several thick coats of oil paint; but without proper plant it will be hopeless for you to try to make anything like a good floor-cloth. With regard to the mark on your table a good deal will depend on the extent of the injury. If it is slight, and the polish only is damaged, it may be only necessary to touch up with French polish. On the other hand, if the wood is injured, you will have to scrape or paper down, or even to plane off the surface and repolish the top as if it were new.—D. D.

**Anti-vibrator.**—DENNISTONE.—The "difficulty" which you have anticipated in respect of the brake action being interfered with may be got over by the arrangement shown in accompanying drawing. If the brake at present on your machine is long enough when full on to reach the wheel when the spring is extended to its fullest, you need not alter it, but can get over the difficulty by attaching foot-rests to the ends of levers, as shown at D, Figs. 1 and 3, by which you may apply the brake with your feet and hand combined. If your brake-

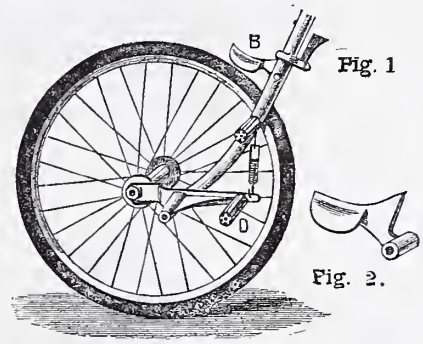


Fig. 1

Fig. 2.

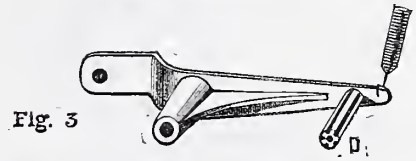

Fig. 3

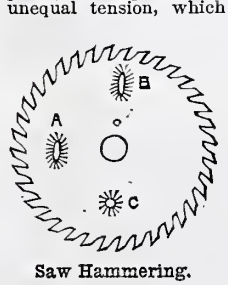
**Anti-vibrator. Fig. 1.—Wheel complete. Fig. 2.—Form of Rigid Brake-spoon. Fig. 3.—Oscillating Lever with Foot-rest attached.**

spoon does not descend far enough, you could make a new one of the form shown at Fig. 2; the back part of the casting, B, being made far enough back, could be filed down until the brake-spoon rested in the right position, and then the whole screwed up tight and rigid. In the latter case, of course, the brake would be applied by the feet only.—CYCLOPS.

**Rushes.**—J. D. (*Clitheroe*).—The best and most practical advice I can give you if you want to reseat with rushes is when undoing a seat to notice how the rushes are twisted, and copy the method.—D. D.

**Saw Hammering.**—J. S. (*Keighley*).—You wish to know the difference in the effects of a blow on a saw-plate when struck with the cross-faced hammer and when struck with the dog-head hammer. The cross-faced hammer is used for straightening and not to regulate the tension of the plate; a saw-plate may be perfectly true, but of unequal tension, which may not be discovered until the saw has been set to work. Unequal tension may be discovered by bending the plate with the hands, as stated in WORK, No. 119, p. 235. This may be removed by using the dog-head hammer, the face of which is rounded so that the effects of its blows will extend equally as shown at C in this sketch of a circular saw. The effects of blows delivered by the cross-head hammer will be as at A and B. The blow at A will be struck with the transverse face of the hammer, and the blow at B with the face parallel to the handle. In some cases the cross-faced hammer will generate a similar effect to that of the dog-head hammer, by striking first with one face and then with the other face of the hammer, crossing the blows, distributing the hammer effects more equally than if the blows were in one direction. In WORK, No. 119, p. 235, I gave instructions as to how to take out a loose place in a circular saw. It may be taken out with the dog-head hammer alone; but it must be understood that sometimes a loose place is caused when it cannot be taken out with the dog-head hammer, and the cross-faced hammer has to be used. I refer to a place caused by over-heating when working the saw, causing blister.—A. R.



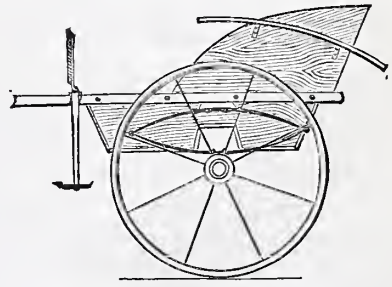
Saw Hammering.

**Stain.**—W. J. H. (*Reading*).—I fancy you have been misled as to the name of the stain you require, acacia being the technical name for gum arabic, which is rarely used for staining purposes; but this gives no clue to the colour you require. If you can send us a sample of the colour, I shall be pleased to assist; meantime, read carefully through "Shop" for the last three months. Many hints appear on staining and varnishing walking-sticks, which are equally applicable to umbrellas.—LIFEBOAT.

**Painting Texts for Church Walls.**—G. M. H. (*Derbyshire*).—Yes, they are commonly painted on zinc. From this you should have your scrolls cut, and, as far as possible, so arrange them that the joinings may come where the "returns" and "turnovers" of the scrolls occur. Both for painting and fixing, you will find it more convenient to have your work in detached pieces than to have the whole soldered together before beginning. Sheet zinc is sold by the pound, and the price per foot will vary with the gauge; but you may roughly set it down at 1½d. or 2d. Zinc texts look best fixed up with plain brass-headed nails. As ground colour, scarcely any other than buff is in ordinary use; but care should be taken that it does not too nearly approach the colour of the walls. What is called a "blush buff" will tell best on some walls, on others a greyer tone will be more effective. On the turnovers a positive ground colour will be used. When the ground is thoroughly dry, the gilding should be first put in, and to prevent the gold leaf from sticking in wrong places, adjacent parts should be dusted over with powdered whiting. All gold work should be boldly outlined with black, as should also the edge of the scroll, so as to cut it off distinctly from the wall. G. M. H. will find choice of alphabets published for church decorative work. The characters are most readily put in with stencil plates, and finished with the brush. Sacred names and initials are usually put in with gold or red, and subordinate characters with blue. The drawback to zinc is that it is liable to cockle, and the text may instead be painted direct on the wall itself. The space to be painted has first to be gone over with a preparation, which stops suction and prevents damp coming through. This is made by dissolving gutta-percha and shellac in naphtha; the solution must be so thin as to work freely, but not so thin as to run. When this method is employed, texts are often painted without scroll-work, and in that case the lettering is set out on the wall, and each separate letter is first painted over with the solution, and again, when this is dry, with colour.—S. W.

**Anti-vibrator.**—W. E. H. (*No Address*).—You are right in supposing that on lifting the machine the wheel would drop down; but obviously it could not drop more than 2 in. If you object to this, you could screw a stop-pin in the fork side just above where the lever rests, so as to catch it when going too far up. With reference to the wheel catching the mud-guard, its altered position places it so much further away from the fork top and guard that you need not fear this happening, provided you have the spring strong enough.—CYCLOPS.

**Oxford Cart.**—G. J. W. (*Antrim*).—I cannot form a very clear idea of what you want, either from the name you give or from your sketch.



Oxford Cart. (Scale, ⅓ in. to 1 ft.)

From the latter, however, I gather that the cart you require is to carry two persons only. I therefore give a sketch of a simple and easily built vehicle (scale, ⅓ in to a foot), and refer you to Vol. I., No. 19, p. 295, where you will find an article on a "Battlesden" cart, which will help you, as many of the details are similar. To give dimensions of the various parts would occupy too much space for these columns; besides, these will altogether depend upon the size of the animal you intend the cart to suit. But if you follow the scale given, you will

have a cart for a "polo-pony" size—*i.e.*, 14 hands high.—OPIFEX.

**Papers for Watchmakers.**—E. T.—There is the *Horological Journal*, published monthly (1st of each month), at Northampton Square, Clerkenwell (price 3d.), which may be had through any bookseller, or direct from the Secretary, Horological Institute, as above. I have taken it the last twelve years, and find it very useful. Then there is the *Watchmaker, Jeweller, and Silversmith*, published at 68, Fleet Street, London (5s. per annum, or 6d. monthly), in which useful information is to be had. I know of no others of much utility.—A. B. C.

### III.—QUESTIONS SUBMITTED TO CORRESPONDENTS.

**Spray Diffuser.**—POTTER writes:—"Will any reader give me directions for making a machine to work by hand for blowing insecticides in the form of fine spray, as it is very much wanted in large greenhouses?"

**Measurement of Paraffin Barrels.**—PARAFFIN writes:—"Will you inform me through WORK how the measurement is reckoned in paraffin barrels? For instance, on the end of the barrel is '120 tests;' what is the meaning, and how is it reckoned?"

**To Preserve Stone.**—H. L. P. (*Montrose*) asks:—"What is the best preservative to prevent from decay a church steeple built of carboniferous sandstone and exposed to the sea air? Has it been used anywhere with success?"

**Coal-dust Bricks.**—G. R. (*Swinton*) asks:—"Will any reader of WORK kindly inform me what the coal-dust bricks are made of? I understand they are made of coal-dust, pitch, and other ingredients, but what are the component parts? Is it a patent? If so, who is the patentee and manufacturer?"

**Heating Small Greenhouse.**—NEWLAND asks:—"Will some reader of WORK kindly tell me how I can fit a heating apparatus to two Rippingill oil stoves with 3 in. burners? I want to keep the frost out of a small greenhouse 12 ft. by 5½ ft. The stoves by themselves are not sufficient. I think some system of a boiler and piping might answer, but I do not understand the working of a hot-water apparatus."

### IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Bread-cutter.**—C. P. WEBB writes, in reply to JEAN (see No. 127, page 366):—"A simple bread-cutting machine may be constructed as follows: Take a piece of beech, or other hard wood, 18 in. by 12 in. by 1 in., planed smooth, and nicely squared; then take a strip of iron, ½ in. thick, ¾ in. wide, 19 in. long; heat one end and bend up 1 in. close, then bend up the whole in half, so that you leave a space between the two sides of ½ in., as shown at A (Fig. 1); drill two holes, countersunk one side as shown, on one of the shorter sides of the board at 1½ in. from the side; cut out a piece ¾ in. wide by ⅜ in. deep; screw this piece of ironwork on, as at A (Fig. 2). Now cut two pieces of the same iron—one 2 in. long, the other 7 in. long; drill a hole at ½ in. from each end of the longer piece, and a hole ¼ in. from one end of the shorter piece, and two holes—countersunk—at the other end; cut a small piece, ¾ in. wide and ½ in. deep, out of the side of

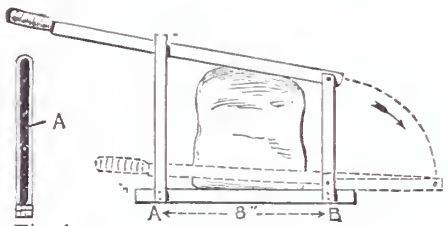


Fig. 1. Fig 2.

Fig. 1.—Guide for Knife. Fig. 2.—Machine complete.

the wood base at 8 in. clear from the other. Rivet these two pieces together, so that they work easily, and screw them on to the block as at B (Fig. 2). Now take a knife, with a blade stout and sharp, and about 16 in. long; at about ½ in. from the point drill a hole. Pass the blade through the groove in the upright, edge downwards, and rivet it loosely to the end of the iron at the other side. All this will be better understood by a reference to the sketches. The machine is now completed. To use same, place the loaf on the board, just overlapping, and with one motion press and push the knife by the handle, which will cut off a slice; lift the knife and repeat until the whole is cut up."

**Heliograph.**—C. P. WEBB writes, in reply to R. N. (see No. 129, page 398):—This little instrument is used for the purpose of signalling by means of flashing the reflection of the sun's rays, according to a pre-arranged code, and is most simple in its general principles of construction. I am not cognisant of the details of the instrument in use in the Army Signalling Department, but one made in accordance with the following instructions will be found thoroughly effective: Take two pieces of any hard wood, say, 12 in. square, and hinge them together on one side so that they open in the form of a hook; at the opposite side, and about 1½ in. from the edge, place a small thumb-screw for the purpose of opening and closing the boards to give proper elevation to the instrument. Now procure a small circular mirror, 6 in. diameter, fitted into a tin back and rim, which can be obtained at a turnery or hairdresser's shop. From the exact centre of the tin back cut out a circle 1 in. in diameter and clean off the quicksilver from this space at the back of the glass; this is for the purpose of seeing from the back that the mirror is directed towards the spot it is desired to signal to. Draw a line across the back, and at each end, close to the edge, solder a very small ring, also a similar ring on the edge half-way between the two; the positions are indicated in Fig. 1, A, B, C. Now take two strips of iron—say ⅛ in. thick, ¾ in. wide, and 9 in. long—and bend them as shown at E and F (Fig. 1). Drill small holes through them, G, H, I, J, K, L, and rivet them together at H and I. This will be fully shown by a reference to the sketch. Take a steel knitting-needle, pass it through the hole J, then through the two side rings at the back of the mirror and through the hole K; secure the ends that it does not slip out. The glass will now swing in a frame, as it were. Affix this portion

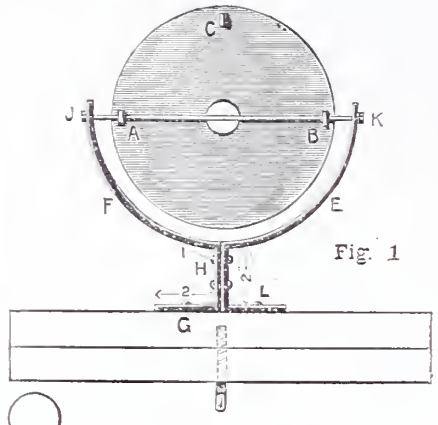

Fig. 1

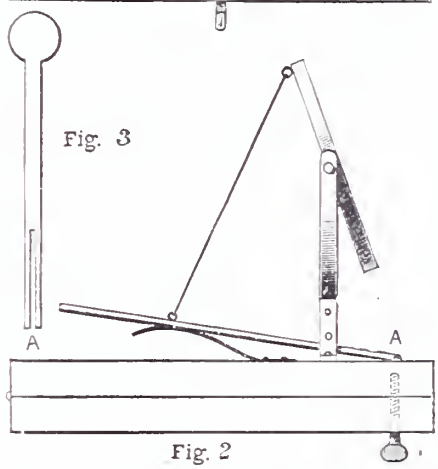

Fig. 2

Fig. 1.—Front View of Helioscope. Fig. 2.—Side View. Fig. 3.—Lever hinged to Stand.

to the stand by screws through the holes G, L, in the centre of the stand, about 3 in. from the edge. Take a piece of hard wood, 9 in. long and ¾ in. thick; shape it as Fig. 3; hinge the end A on to the stand at about 1½ in. from the front edge, as shown at A (Fig. 2). Get a small piece of steel spring, attach it to the stand, and bend it so that it comes under piece A in Fig. 3. Now get a piece of moderately strong wire, say about 9 in. long, make a hook at one end, which put through the ring at the top of mirror, and clench it; attach the other end to the lever, and the instrument is complete. Upon tapping the end of the lever the mirror will oscillate and flash the sun's reflection. It is a very simple matter to arrange a code of signals. If this explanation is not perfectly clear, I shall be happy to further elucidate it through the medium of 'Shop.'"

### V.—BRIEF ACKNOWLEDGMENTS.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—IGNORAMUS; WOODCUT; M. P. (*Peterboro'*); T. H. W. (*Wolverhampton*); LIONEL; BRASS FINISHER; REPAIRER; P. E. (*Tipton*); E. W. (*Cupar, Fife*); A. B. (*Salford*); T. A. E. (*Clapham*); H. J. M. (*Bristol*; S. W. (*Blackburn*); H. D. VOL. III.—No. 138.] SATURDAY, NOVEMBER 7, 1891. [PRICE ONE PENNY.

### HOW TO MAKE A KITCHEN DRESSER.

BY F. JERMAN.

INTRODUCTION—DIFFERENT KINDS OF DRESSERS—MODERATION IN ORNAMENT — GENERAL DESCRIPTION AND DIMENSIONS—FRONT FRAMING—FRAMING AT ENDS, RAILS, AND BEARERS—POT-BOARD — SHELVES AND STANDARDS — DRESSER TOP AND SIDE BOARDING—DRAWERS—DOVETAILING—CUPBOARD FRONT—BACK—WOOD AND TREATMENT—CONCLUSION.

ARTICLES of furniture in daily use are very often made without consulting the wants of the inmates of the house for whose use they are intended. This remark is especially applicable to the ordinary kitchen dresser. In terrace houses the dresser is generally mentioned and described in the specification, and put up by the builder of the house, who gets his notion from a few words running after this fashion :—"Provide and fix in kitchen a dresser formed of 1 in. clean deal frame, sides, and top, 2 ft. wide, with two drawers and two cupboard leaves in bottom, all on stout bearers, with 1 in. deal shelves and pot-board. Put small bolt and turn-button to cupboard door, and fix two dozen cup and jug hooks at edge of shelves." The reader will see that not much idea of design is given in this clause : the size also is very lightly passed over. In consequence of this, dressers in most houses are erected in a character approaching sameness. Go into one of a terrace of houses, look at the dresser, and you have seen all of them. They can hardly be called articles of furniture, being generally landlords' fixtures, not to be taken away when the tenant removes.

Sometimes we see them without any shelf room provided, making the article look like

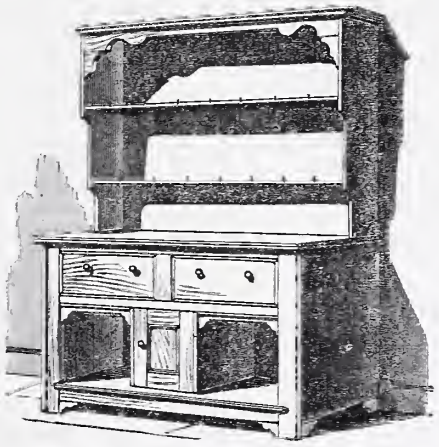

Fig. 3.—Perspective Sketch View of Dresser.

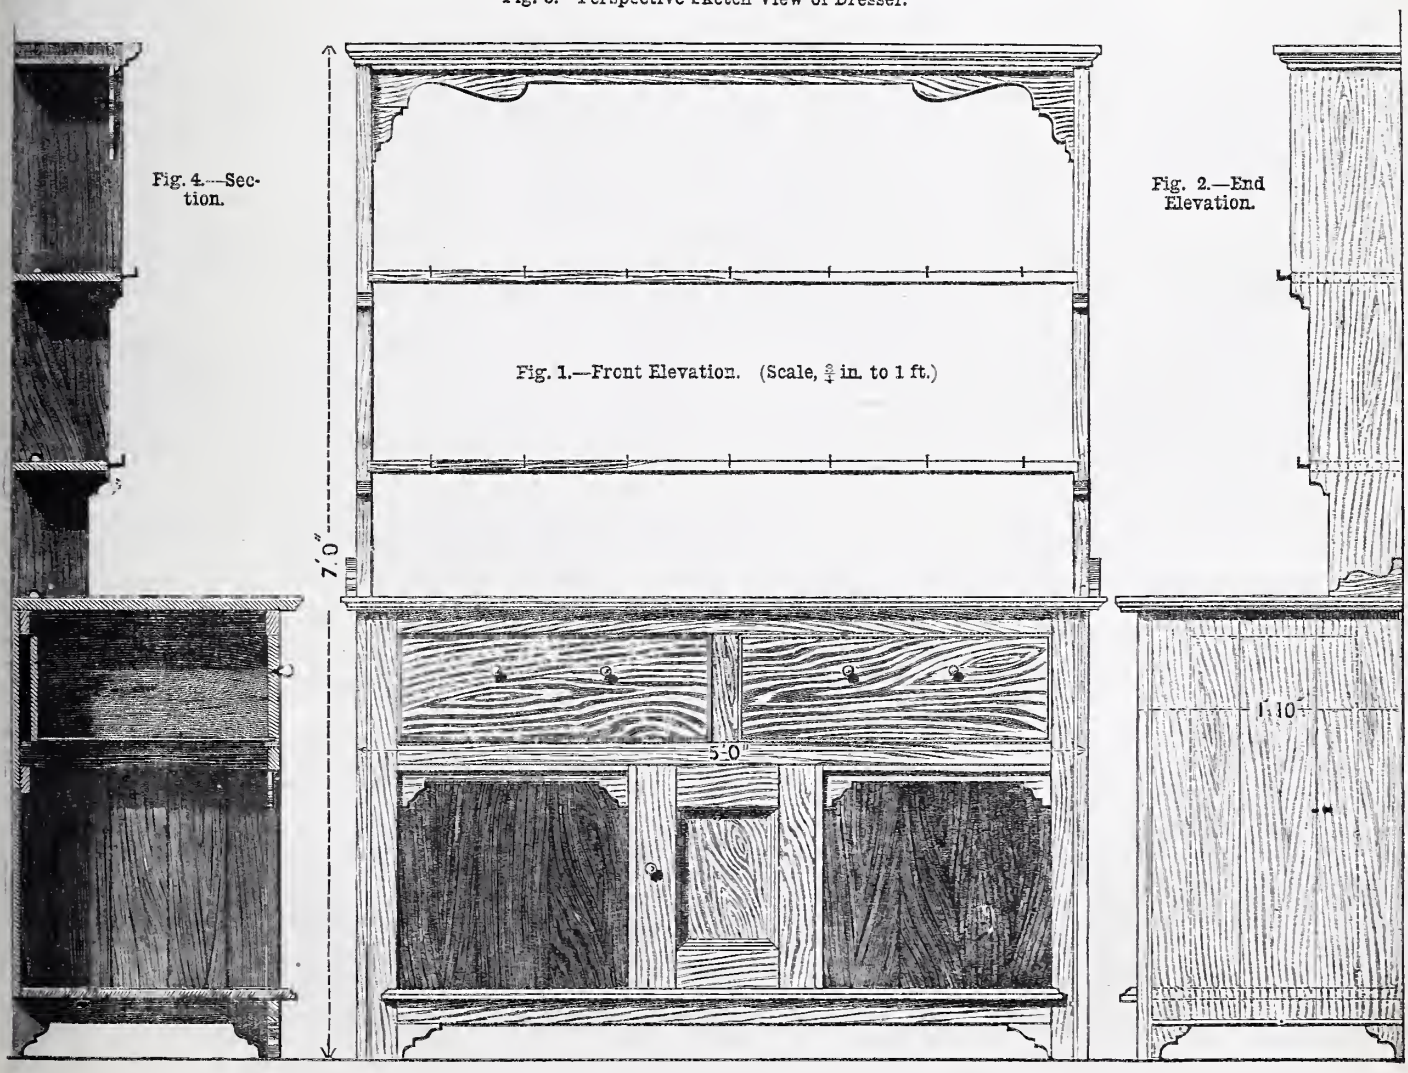

Fig. 4.—Section.

Fig. 1.—Front Elevation. (Scale, $\frac{3}{4}$ in. to 1 ft.)

Fig. 2.—End Elevation.

a very plain buffet or sideboard. On the other hand, a gaunt-looking stretch of shelves, knocked together without any thought of proportion, and reaching close up to the ceiling, serves the purpose of a dresser in some kitchens.

By this introduction I do not wish to convey to the reader an idea that a dresser should have a quantity of meaningless ornament, panelling, and mouldings stuck on; but that it should be strongly put together, at the same time with an eye to effect and proportion. Cut work can be introduced here and there, formed with the keyhole saw; and it is surprising how a little of this kind of ornament takes the baldness and commonplace look out of a simple design.

The dresser shown here, I think, fills the conditions mentioned above. It is made in two portions, the shelves and end standards forming one part, and the top, with two drawers, cupboard, etc., the other. In case of removal this will be found very convenient. The shelves must, however, be firmly fixed to the wall with L irons to prevent any likelihood of its tipping over. The total width is 5 ft., the breadth 1 ft. 10 in., and the height—7 ft.—is very convenient, being at the same time not out of proportion with the other dimensions; 3 ft. 2 in. from floor to top will be found suitable, at which height I have shown it.

The framed front had better be commenced first. It is formed of 3 in. by 1 in. upright pieces and 2 in. by 1 in. rails tenoned into them. A piece of 2 in. by 1 in. is also tenoned into the rails in the middle between the two drawers. The two upright pieces have beads worked on their edges, the length being 3 ft. 1 in., and the rails are 4 ft. 6 in., plus the tenons at each end, which will make the total length of rails 4 ft. 8 in.

The two ends are framed in a similar manner with the same sized stuff, but the stiles have cut ends to form supports as shown. Two rails are fixed at the back, in the position shown in section, tenoned into the sides. The framing and back rails can now be put together, the front to be screwed to the sides and the latter kept $\frac{3}{4}$ in. back from the face to allow for the matched boarding. Bearers must be fixed, two to each drawer, formed out of 2 in. by 1 in. stuff, with $\frac{1}{2}$ in. rebate, in which the drawer slides. They are tenoned into the front, halved, and then nailed on to the rail at back. The length, including tenon, of these bearers will be 1 ft. 9 in. Figs. 14, 15, and 16 show the method of fixing them.

The pot-board can be got out in two pieces. The sizes are to be found in Fig. 6, the total length being 4 ft. $10\frac{1}{2}$ in. and the width 1 ft. $10\frac{1}{2}$ in., cut out at angles to allow for stiles, etc. It projects 1 in. from the front, and has a moulding worked on its outer edge (see Fig. 9). The board has a bearing on the bottom rail of the side framing, shown by dotted lines in Fig. 6. It is also nailed at the front and back. Care should be taken in marking out these boards, so that they will fit closely together when in position without any crack between them. This pot-board is a very useful feature in a kitchen dresser, as a stand for pitchers, etc. The recesses on each side of the cupboard may serve as a place for boots and shoes. A $\frac{3}{4}$ in. board may be placed half-way up 20 in. in length and 9 in. in breadth, nailed to little ledges on each side, so as to give more shelf room if the recesses are used for this purpose. The divisions for cupboard are formed of $\frac{3}{4}$ in. stuff, rebated in front for door.

The end standards are 1 in. in thickness, 3 ft. 10 in. high, and with diminishing widths of 11 in., 9 in., and 7 in., and a hollow cut below each shelf. Grooves are cut $\frac{3}{8}$ in. deep for the shelves, 10 in. from the bottom for the first shelf, and 15 in. is the width between the first and second shelves. The shelves measure 4 ft. $10\frac{3}{4}$ in. by 11 in. and 4 ft. $10\frac{3}{4}$ in. by 9 in., fitting into the grooves in the end standards. As large articles are put away on the top shelf—such as tureens, etc., which are not used every day—it is generally made the widest. The shelves should be at least 1 in. thick. If they are any less in thickness they will require supports, which in some measure decreases the shelf space, and prove in the way when large dishes, etc., are placed there. A small strip is nailed on 3 in. or so from the back to keep plates, etc., upright in their place. Fourteen jug and cup hooks are shown to be screwed into the edges of shelves. The cornice of dresser (Fig. 7) is 2 in. deep, and a 11 in. by $\frac{1}{2}$ in. board is fixed at the top, but this latter can be omitted if desired. The cut spandrel beneath the cornice is formed of pieces of $\frac{1}{2}$ in. stuff fitting into a shallow groove in the sides. The upper piece is 4 ft. $10\frac{1}{2}$ in. long by 3 in. deep, and the two brackets below same are 4 in. by 3 in.

To return to the lower part of the dresser: the top can now be cut out, glued up together, and fixed. It is made of 1 in. stuff, and measures altogether 5 ft. 4 in. long by 2 ft. wide, and has an ogee mould worked on its edge. Two pieces of 7 in. by 4 in. are cut out of $\frac{1}{2}$ in. stuff, and screwed to the top in order to keep the shelves and standards which go between these pieces in place. The $\frac{3}{4}$ in. boarding at sides can now be nailed to the framing; the edge at the bottom is rounded as shown, and the edge against the wall is rebated for the boarding at back.

The knife drawers are made of $\frac{5}{8}$ in. stuff, cut to the sizes shown in Figs. 10 and 11, and with a groove $\frac{3}{4}$ in. from the bottom cut in the front and sides. These and the back are dovetailed together (see Figs. 12 and 13). It will be seen that the sides are dovetailed to the front in a different manner than they are to the back, the pins and sockets not being cut so deep in the front as at the back in order to let the drawer have a plain face, and allow the joints to be seen at the sides only. This is known as the lap dovetail. The dovetails in front must be cut out with the chisel only, but the tenon saw can be used in the sides and back for making the horizontal cuts for the sockets, which are then cut off with the chisel.

It is very important that drawers should be dovetailed together, as a great strain is put on the front when it is pulled out, especially if the contents are heavy. If the drawers are nailed they will not keep together very long. When all is ready, coat the dovetails with thin glue, hammer them together, then slide the bottom in the grooves from the back, and nail it up to the back piece, which is made less in height than the other sides to allow for same. Square blocks are then glued up in the ordinary way to the bottom of the drawers. Two wooden knobs screwed to each drawer will be required for pulling them out.

The cupboard front measures 18 in. by 15 in., and is formed of 3 in. by $\frac{3}{4}$ in. stiles and rails framed together with $\frac{3}{8}$ in. panel, and a small moulding run round outside same. Hang with a couple of butt hinges, and fix a brass turn-button to fasten door. Two 3 in. by 1 in. cut brackets are screwed below the bottom rail to the stiles. Half-inch spandrel pieces cut out of 20 in. by 3 in. stuff are fixed over the two recesses, and a bead is run round at the top against the rail to hide joint.

The back of dresser can be covered with $\frac{1}{2}$ in. boards, laid horizontally all up through; or, if preferred, the lower portion only may be treated in this manner, leaving the wall showing behind the shelves.

The wood used may be red deal, this being easier to work than the white, all to be painted at completion, except the top, which can be made of beech or sycamore, left clean planed off and not painted. The latter wood is very suitable for this purpose. Bread-plates and articles of a like nature are made of it, and as it has a very even grain splinters will not appear, no matter how hard it is scrubbed. If the remainder of the dresser is painted a stone colour it will form an excellent contrast with the white sycamore top.

The sketch (Fig. 3) will give an idea of how the dresser will appear in execution. Should there be any points which the reader may not be clear upon, I shall be glad to correspond with him through your "Shop" columns.

## ARTISTIC LITHOGRAPHY.

BY MISS ADA J. ABRAHAM.

### Practical Work—Conclusion.

To lithograph a written circular or letter, pin the original to a drawing-board at each corner, then take a sheet of transfer paper, cutting it to the necessary size, and if the sketch is not subsequently required, gum the top of the transfer paper to the top of the letter, that being a safer way of securing it from slipping than if drawing pins were used; in such case make it further secure by using a paper weight, and all tracings should be done in the same manner. It should not be fixed at the bottom, as then it can be frequently lifted up to see if the lines are being followed correctly. The student must not forget that there is a right and wrong side to the paper, and he must use a hand-rest so as not to touch the paper if possible with the hand, or the heat will make it curl up.

Now write over the original very carefully either with the pen or brush, and be sure to notice the different thicknesses of the lines, and any peculiarity in the writing, not forgetting the stops, etc. If there be any ruling, place a small piece of cardboard on either side of the paper, and let the ruler rest on this, in order to avoid touching the drawing.

The ruling pen should be filled by means of an old brush, and not dipped into the ink, else the outside of the pen will soon get inky, and so smear the ruler, and likewise the drawing. The pens and brushes should invariably be tried first to see if they make lines, or dots, of the desired thickness; and this, mentioned now, should be followed out in every case.

After the writing is done, the artist's part of the work is so far finished, and it can now be handed over to the printer, who will first transfer it to stone, and then print the impressions from the stone. But the artist should always insist on seeing a proof first, to correct any mistakes. The drawing should be sent perfectly flat, and no tracings or writings should be rolled when drawn with lithographic ink.

If a mistake is noticed when the proof is submitted, or any of the lines do not print as black as the rest, it is necessary to retouch

up the stone in those parts, first preparing it with the acetic acid as previously alluded to. The artist must be sure to go over the same lines as those already drawn, and this requires a very neat piece of work to avoid making double lines, as he must bear in mind that the drawing is the reverse way to the original sketch being now on the stone.

Any writings or tracings when done on paper should be made, if anything, rather thinner than required, as they may spread slightly in the transferring.

To proceed to the subject of drawing on the stone itself, a tracing of the subject must be made on the ordinary, or végétal, tracing paper, according to the clearness of the sketch; then gum the top corners of the tracing to the stone, taking care to reverse it, slip a piece of the red transfer paper underneath, with the red face to the stone, and go over the tracing carefully with the tracer, lifting it up now and again to see if it is going down satisfactorily. If the drawing is to be worked in chalk, the red line should be made as faint as possible, for although the liquid ink would penetrate through the chalk, it may prevent the lithographic chalk from adhering properly to the stone. If the outline should be too strong, a little talc brushed lightly over the stone will remove some of the red chalk without destroying the tracing. Should the tracing require any alterations, it can be washed off the stone with a clean sponge and water; but the stoue must be allowed to thoroughly dry before re-tracing and proceeding with the work.

Some artists use a looking-glass to work with, but it is not advisable to make a practice of doing so, as it is not then easy to do without it, and there is really no difficulty in getting into the habit of working the reverse way to the original sketch.

In ink work the student must not think because the drawing appears nicely shaded on the stone that it will necessarily print so; perhaps the ink is a little thinner iu those parts where it appears lighter or browner in colour, which will help to give the illusion, but it will all print equally black wherever the ink has touched the stone, therefore any tinting or shading required must be worked in lines or dots. The best teacher is the student's own experience, which he can obtain in an easy manner by working in various ways on a stone and then having it printed.

Black-and-white drawings on polished stones are generally shaded or tinted in lines in imitation of etchings, stipple being reserved for colour work; and whether the drawing be done in stipple or chalk, the outline and markings should be all made first before any tinting is begun, and in the case of ruling that should be done first of all. If any large space for solid is required, it is better first to outline it with the brush, then make the drawing, and fill in the solid last.

To etch the drawing after the work is completed, the stone must be placed flat on the bench, and the brush filled with the etch passed lightly once over the drawing, leaving it as evenly as possible on the stone, taking more as required (being careful not to leave a line showing where the etch is renewed), and the drawing must not in any way be rubbed, which refers especially to chalk work.

Should there be a quantity of solid on the stone, the work does not require the acid as strong as if there be a great deal of strong tinting and very little solid; and also light tinting does not require such a strong etch, but it is impossible to lay down any decided rule for this.

In very particular chalk work it is better not to touch the drawing with the acid brush at all, but to slightly tilt the stone and pour the etch over it, allowing it to run down; and there are special troughs made with fixtures on which to place the stones, and which can be moved to tilt them in any direction; but in any case the etch should be put on as evenly as possible, and allowed to dry before sending the stone to the printer, when he again etches it. Some printers prefer to etch the stone entirely themselves, but it is better that the artist should do this first etching himself, as it is the most important, and he knows exactly how the drawing has been worked, and can therefore judge the necessary strength the etch should be better than the printer; besides which, he is sure the work is not rubbed in any way when it leaves his hands, which might otherwise be the case.

It is a very dangerous practice to cover stones with paper before the gum is dry, as it would stick, and when the printer washes it off it would not be his fault, if some of the work were rubbed at the same time. Some artists are very careless in leaving their stones to be etched until the last minute; for good chalk work the stones should be under etch about twelve hours, but stipple does not require so long. In fact, for some commercial work it is better to etch the stone, and almost immediately afterwards roll it up.

If the drawing were over-etched—that is, having used the acid too strong—the work would disappear in the printing, the acid eating through the ink, especially in fine work; and if not etched sufficiently would not print clearly. But after trying once or twice, the student will soon find out the desired strength it should be.

In lithographing printed letters such as Fig. 23 (page 231), the student can only be advised to do them carefully as he would do on paper, and to use his own judgment whether to gum out the letters and fill in the stone solid, or rule round the letters and fill in the spaces, leaving the letters open, it being possible to do them either way, if the letters are required to be left white upon a coloured ground. If the letters are coloured it must be just *vice versâ*, the letters filled in solid, and the spaces left, but when spaces are gummed out the ink should be dissolved in turpentine instead of water, to prevent it mixing with the gum, otherwise parts that are not required would perhaps roll up black.

A very effective monochrome drawing can be done by printing it in two colours—namely, a drawing stone, and a tint. Do the drawing as if it were only to be done in black and white, and have it printed either in red, sepia, grey, or black, according to taste and the nature of the sketch; then have an offset taken from this just the same as if it were a tracing, using the drawing-stone as if it were a key-stoue, and fill in this second stone solid, excepting the high lights (the red impression on the stone from the original drawing will show where the high lights would come), and if a grained stone be used, the solid can be shaded off or left sharp as required. If the drawing is printed in a dark sepia, aud the tint in a very pale shade of the same colour, the white paper being left for the high lights, a very pretty effect can be obtained from the one drawing.

In the case of small cards, or drawings, it is possible to do several on the same stone, only they must be placed in proper positions to allow for cutting and trimming them to the size required.

I took for our last subject, as an example, a chromo-lithograph in half a dozen printings, namely, gold, yellow, blue, pink, brown, and grey, showing the working of each colour, and at the same time making it applicable to any drawing in any number of printings. As I went into the matter as fully as space would permit, I need not say much on the subject in addition to the supplementary remarks I have felt called upon to make in this my concluding paper on the method of lithographing circulars and letters.

It seems to be a general idea that chromo-lithographic drawings are worked on the stone in colour, but this is a very great mistake, and gives an entirely false notion to anyone unacquainted with the work; for to refer back to the first principles of lithography, every colour is worked on the stone with the lithographic ink, which is black, and after the stone has been etched, the ink being of no further use, is washed off, and the required printing ink rolled on the stone whilst it is damp, it being necessary to do this for each impression taken; and as the printing ink adheres to the preserved portion of the stoue, it does not make the slightest difference whether it is black or coloured. The following is a good and useful order for printing: gold, silver or bronzes, yellows, blues, pinks, reds, browns, light greys, dark blues (if any), dark reds, and dark greys.

Some artists begin with all the light colours, and gradually work down to the strong ones, but I should advise the artist, from practical experience, to get a strong colour on the proof at au early a stage as possible, as it will throw all the other colours back to their proper places, and so do away with the necessity of using extra colours, or re-proving the whole thing again.

## WIRE-WORK IN ALL ITS BRANCHES.

BY JAMES SCOTT.

### Dog Muzzles and Gas Globes.

Dog Muzzles—Nose Wire—Cheek Wire—Nose Rings—Drop Wire—Gas Globes, First Stage, Second Stage, Final Stage.

**Dog Muzzles.** — What the present canine generation really think about the manner in which their noble heads are encased within cages provocative of tantalization, I, and everyone else, I believe, will be unable to determine, unless trausmigration of souls is a truth (which I doubt), and at some time or another is closely connected to spiritualistic revelation, when, perchance—but let this drop; it is but an exceediugly improbable theory.

The dogs themselves, however, do not appear, generally, to take any more notice of the metallic obstructions to their complete happiness than they would of a pimple—both are encumbrauces which certainly annoy them, but which they accept in good spirit. Pinch a dog; pull his tail; and the treatment is different. He will not endure it. But as muzzles exist, I will for a time be the dogs' unwilling foe by letting out a few remarks as to how these guards are made to prevent them from nibbling their benefactors and from kissing each other.

There are so many different patterns of muzzles that it would be well-nigh impossible to describe them all without wearying the reader by giving him several pages of particulars; and as I am limited to space in proportion to the several articles I have

undertaken to write upon, I must confine myself to the unit one in dealing with them.

In passing, I might mention that there are several patented muzzles, during the wearing of which dogs are permitted to eat and drink at will, without there being a possibility of their biting anyone. It is obvious that, did opportunity offer, a description of either of these would be of but little use, as in such a case the patentees would be very suspicious that some readers

where shown separately in other diagrams, are similarly lettered to secure identity.

*Nose Wire.*—To the bench, or to loose boards for the purpose, are driven a number of short iron pegs, in the manner shown in Figs. 112 and 113. Those in the former diagram are used for forming the nose or crown wire, while the pegs, supposed to be in Fig. 113, are those around which the side or cheek wire is bent. A straight wire, with an eye-hole of the shape indicated, is

first two pegs, on the inner side of the fourth, outside the fifth and sixth, and so on, finishing up at the other end in an eye-hole. If more than one muzzle is to be made of the same size, follow the hints I give for ascertaining the proper straight lengths of wire necessary in my remarks on the formation of hooks in the paper concerning fire-guards.

*Nose Rings.*—When the nose and cheek wires are ready, solder them together at

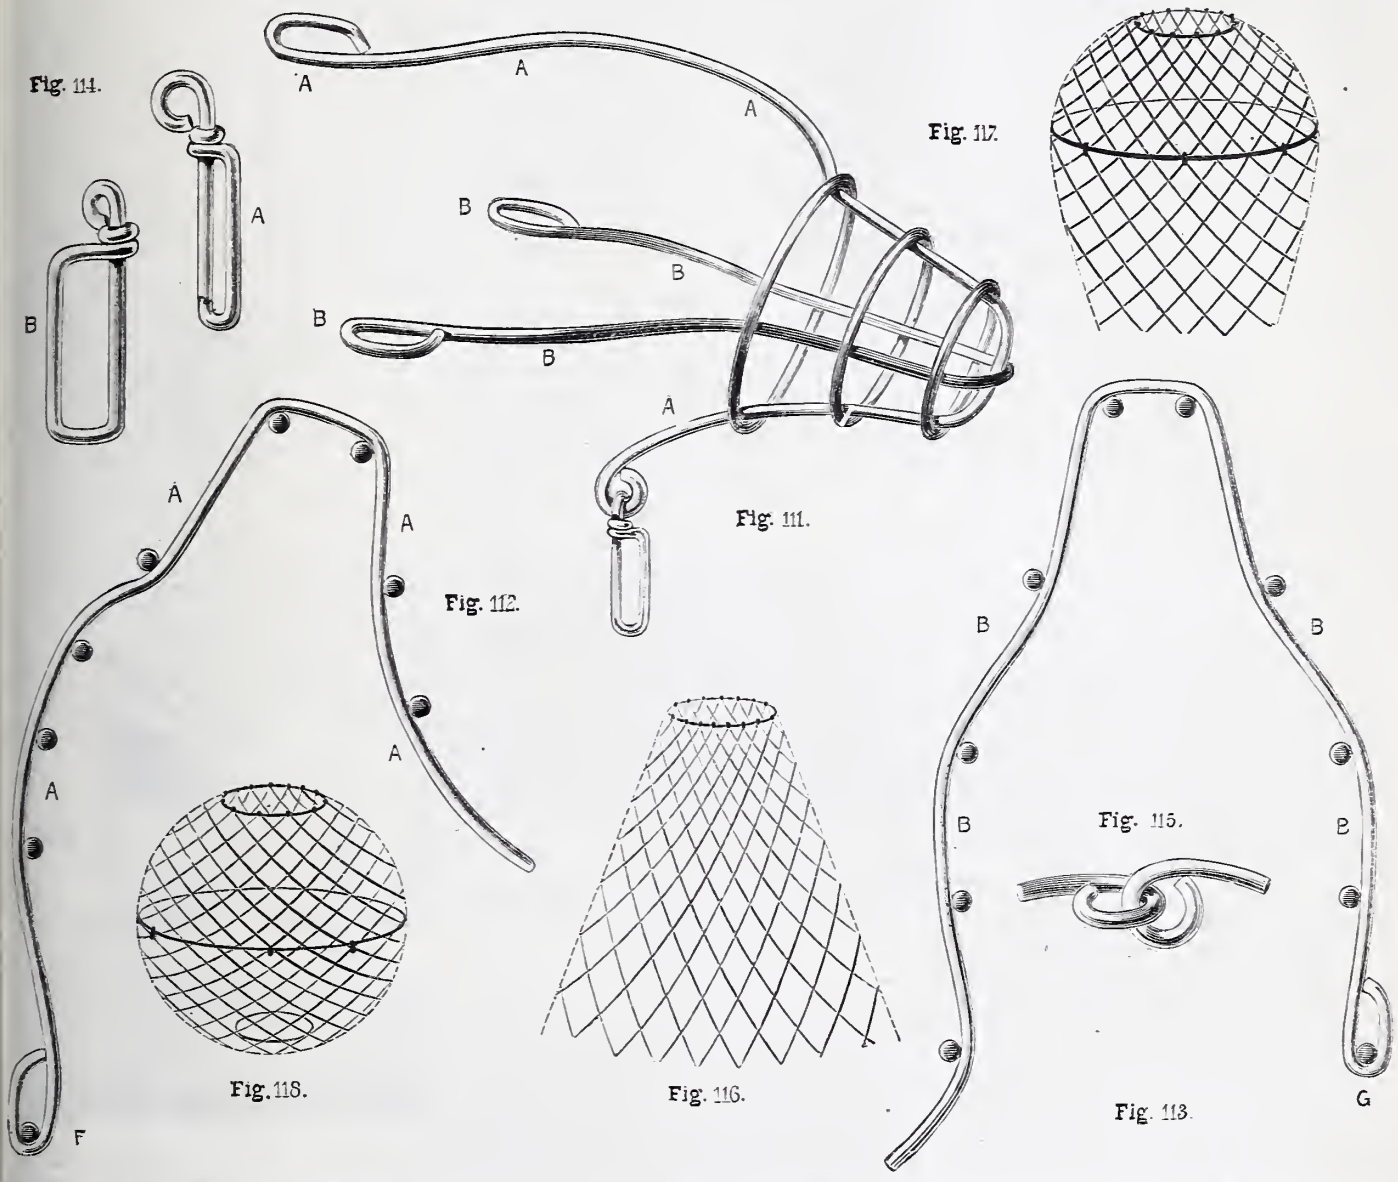

Fig. 111.—Common Pattern of Dog Muzzle. Fig. 112.—Nose or Crown Wire laid upon Bench and bent around Pegs. The Wire is hitched on to Peg F, and bent in due order outside and within the remainder as shown. Fig. 113.—Cheek Wire laid upon Bench and bent around Pegs. The Wire is hitched to Peg G, and treated in same manner as shown in Fig. 112. Fig. 114.—Two Views (A and B) of Eyes for Strap. Fig. 115.—Eye-holes to complete Nose Rings. These Holes are at the bottom of the Rings, and must be squeezed closer than shown here. Fig. 116.—Gas Globe of Crimped Wire: First Stage. Fig. 117.—Ditto, Second Stage. Fig. 118.—Ditto, Third Stage.

ight avail themselves, without permission, f the manufacture of such. It may be hat is generally vulgarly termed a "come-own" from patent muzzles to the very ommon pattern shown in Fig. 111, but this the article I propose to deal with.

The dog for whom the instrument of tor-ure is intended would be the best judge as o the sizes required; but, unfortunately, iese animals cannot make their desires nown to us; therefore it is necessary for ie choice to be left to our humane judgment. reference to Fig. 111 will show that I have ttered the wires represented. These wires,

hooked to peg F (Fig. 112), while the wire is carried in and out among the other pegs, as represented in that diagram. Continual practice will be expedient to accustom the operator to properly bend the wires, as, although it is easy enough to guide them properly around the different pegs, it will be noticed that, upon release from them, they will spring out considerably.

*Cheek Wire.*—In Fig. 113 is represented the cheek wire in plan. An eye-hole is formed at one end and hooked on to either extreme peg, from which it is continued, in the manner shown, on the outer sides of the

their junction. Three oval-shaped rings are then required, a small one for the front of the nose, a larger one for the middle, and one still larger for the back. They will be soldered in position outside the nose and cheek wires, with their eye-holes uppermost. Each of these ring wires will be formed round an oval block or ring fixed to the bench. An eye-hole will be formed, hooked to a peg at the head of the block, and the wire drawn round it, and the end passed through the first hole and squeezed down tightly over it (Fig. 115).

*Drop Wire.*—As most people may know,

there is a drop eye-wire underneath the muzzle, attached loosely to the lower eye-hole. It is shown in Fig. 114, on the right-hand side of which is a side view of it, while on the left is shown a front view. It is such a difficult matter to illustrate portions of wire-work in an understandable manner, that I have shown this hook, or rather two of them, as hanging upon a block. Solid articles, such as furniture, can be made clear by variations of light and shade; but with such open work as I am labouring with at present, it is impossible to obtain many degrees of light and shade. In Fig. 114 the main portion of the hook is supposed to be exposed in full before the reader, while the top eye-hole is receding from him. On the left-hand side the reader may imagine that he sees the main portion edgeways, projecting from the paper, while the eye-hole is flat and full before him.

This hook is for the reception of the strap, which also travels through the remaining eye-holes in the nose and cheek wires. Fig. 114 is drawn to a much larger scale than the diagrams, Figs. 111, 112, and 113.

I wish to whisper a hint into the ears of my amateur friends who possess dogs, as to how they may obtain the proper shape to make a muzzle to fit their particular canine companion. Come in, take a seat, while I ask your jealous professional brethren to wait outside, lest they condemn me for assisting you. First, catch your dog. Next, coax or compel him to stand close up against a wall, while a shadow of his head is cast sideways upon the latter by the rays of a lamp close by. Then pencil along the outline of the shadow of the head, if the dog will allow you to, after which he may be released. Measure the dog's head from the nose to between the ears, and also the sketch from the nose to the ear. If they coincide, well and good; if not, reduce proportionately the sketch within the original outline until satisfaction results.

You may then, to arrive at the length the nose wire must be, place a piece of string against and completely along the outline, having just so much as will cover it entirely. If a piece of paper or card be hung to receive the shadow, the outline upon it can be used as a guide for the necessary pegs around which to bend the nose wire.

**Gas Globes.**—I will now pass from articles devised to prevent our four-footed friends and foes from giving us sundry bites, to articles invented to debar a more serviceable friend and more dangerous foe, viz., fire, from annoying us.

The utility of gas globes must be evident to all. They secure gas jets from the approach of pieces of paper, etc., that may happen occasionally to be blown about an apartment, curtains from being forced into direct contact with the same, and in numerous directions affect good by guarding the flame and debarring it from being the means of creating damage by setting fire to inflammable material.

*First Stage.*—I must refer my readers to my article upon "Splicing" (No. 123, page 292). There they will observe that I show a cylindrical piece of work, which is obtained by a certain number of straight crimped wires put together, and then bodily bent round and spliced. It is from such a piece of work, but consisting of many more wires, that these globes are made. A comparatively small ring is put *outside* the top end of the work, the wires at that part being drawn close together, and those which the ring comes in contact with turned over on to the latter. There will be a considerable decrease in the size of the meshes adjacent to this ring when it is fitted, the work having a tendency to assume an appearance similar to that of Fig. 116. In order to secure the ring in position whilst the wires are being permanently fixed to it, it is advisable to, at first, turn over one here and there, say, in about four different spots.

*Second Stage.*—The next operation is the fixing of a large ring, which ring will be placed *within* the wires composing the globe. This will be found a more difficult part to accomplish. The ring must be pushed into the work gradually, the bottom wires in Fig. 116 being occasionally drawn apart as this is done.

The length occupied by the work during these movements will decrease to a great extent, and, consequently, the bottom meshes will become more open. When the ring is pushed in to the proper distance, the curves of the wires will look something similar to those shown in Fig. 117, and the ring is secured by being tied in six or seven different spots.

*Final Stage.*—The placing of the bottom ring will be found a more difficult job than fixing the top one; it should be smaller than the latter. While being finished, if the work does not appear to be assuming a truly globular shape, it can be made to do so by bringing equal and steady pressure to bear upon it, one opening of it being in direct contact with the bench. If all is properly done, the globe will look like Fig. 118.

While fixing the bottom ring, *outside* the wires, gradually gather the loose ends together with both hands, until they can be easily grasped in one hand only; then slip the ring on, and temporarily secure it by fastening a wire here and there, previous to turning all of them over on to it.

It was my intention to also give particulars here of the more ordinary pattern of gas globes, but as the present paper has occupied sufficient space for this week upon this branch of industry, I must postpone descriptions until a future time.

## HOW TO MAKE A PAIR OF LEATHER SLIPPERS.

BY W. GREENFIELD.

This brief article, in reply to a query put by Novice (*Stockport*), necessarily assumes this form, as it is too lengthy for "Shop."

I have come to the conclusion that you want the most simple way of making a pair of slippers. Your *nom de plume*, and asking what tools you need, tell me you are not far advanced in the trade, but I wish you had told me what you wanted to make them—pumps (single sole) or welts (double sole), or if you only want to make them riveted or pegged, which is often done for rough wear.

Had I but known which, I should have answered before, but as it is, I have waited till I had time to tell you the way to make a proper pair of slippers. You can, in this style, make them light or stout, according to the substance of the tops, and as they are leather they are worth a good sole. Of course, I conclude your tops are already cut and closed, as you only say make.

This class of slipper is easily repaired, and is by far the best way to make them; that is certainly why I have decided upon them, as I feel sure that a number of readers will welcome the answer to your question, and it will form a good stepping-stone to boot making.

Of course, you have lasts that fit you; if not, you must get a pair.

A shoemaker's necessary kit for what you ask is as under:—Knife, pincers, hammer, sharpening-strop, sewing-awl and handle, lap-iron, piece of smooth board, rasp, buff-knife, and fore-part iron. Bottom stuff and grindery:—Pair of in-soles, pair of out-soles, pair of welts, pair of stiffeners, pair of split

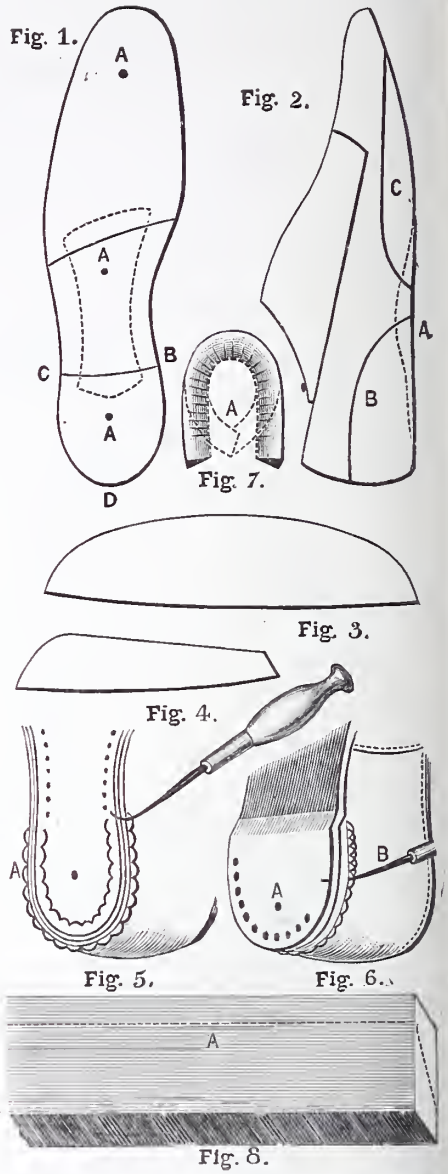

Fig. 1.—In-sole blocked on Last. Fig. 2.—Filling up Waist. Fig. 3.—Stiffeners. Fig. 4.—Side Linings. Fig. 5.—Sewing in Seat and Welt. Fig. 6.—Lift under Sole to form Heel. Fig. 7.—Mode of twisting Split Lift. Fig. 8.—Mode of cutting Leather for Split Lift.

lifts, piece of felt, four side linings, lasting tacks, ball of No. 9 patent hemp, ball of wax (soft for winter, hard for summer), bristles, ½d., sheet of No. 1½ sand-paper, ink, ½d. (shoemaker's), and one hard heel-ball.

The leather can be prepared as shown in No. 112 of Work. While the in-soles are wet, block them on the last, grain side to the last, with three tacks, as shown at A, A, A, Fig. 1; stretch them all round with the pincers, and put a tack in here and there to keep them down over the side of the lasts. Let them get nearly dry, draw out the side tacks, and round up to the shape of the last. A

slipper last should be dead in the waist, and it ought to be thin at the top. These two points are to make them fit tight in the quarters; but if the last is a boot last, then the waist must be filled up by putting a piece of stout soft belly inner-soling in to fill it up and make it almost straight at the bottom, as the plain line, A, Fig. 2; the dotted line, B, showing the curve or drop there generally is in a boot last.

And now I must refer you to back numbers of Work, otherwise I should have to encroach too much on our space.

The next thing to do is to fit and hole the in-sole, and by referring to Vol. II., page 796, No. 101, you will find all this fully explained in the answer to A. B.

Next comes the fitting the welt. This you will find in the answer to H. G. (Vol. II., page 733, No. 97).

The stiffeners are the shape of Fig. 3, only they are about 9 in. long and 2 in. wide; they are skived a little at the bottom, and round the top they are skived to *nil*. Their place in the slipper is shown by B, Fig. 2, and they are put in between the upper and lining.

The side linings are skived in a similar way. They are the shape of Fig. 4, and one is put in at each side, as shown at C, Fig. 2.

Next comes the principles of lasting, and these you will find fully explained in the answer to Snobby (Vol. II., page 717, No. 96), with one exception—slippers must not be pulled over tight in the waist, or it will tend to make them loose in the quarters.

And now you must be referred to the last article on "Boot and Shoe Repairing," which appeared, as you may remember, in No. 137, and is on "Welting and Soling Hand-sewn Work." From this you will see the way to sew your welt, only it will have to be sewn in from B, up the waist and round the toe to C on the other side (Fig. 1), and after you have sewn to C, sew your seat round from this point to B, passing D; or the seat can be sewn in first and then the welt, as A, Fig. 5. Then you put a shank in—that is, a piece of leather in the waist, as shown by the dotted line—or the whole can be filled up, as the bottom of the fore-part, with felt, as will be seen in the above-named article, which also tells you how to put and stitch the sole on; and in this case the waist can be sewn, as for a slipper it is hardly necessary to stitch it.

For slippers, a heel need not be built, as it is for a boot, but the sole left long at the back, and this can form the heel-piece. Of course, it wants to be thicker here to form the heel, and this is done by putting a whole lift and a split lift under the sole at A, Fig. 6. A split lift, or rather a pair, is a strip of thinnish sole leather, about 6½ in. long, and about ¾ in. or 1 in. wide. This is well wetted and split down the centre, holding it flat on the board and knife quite slanting, and follow the dotted line as shown in Fig. 8. Each piece is held flat on the lap-iron and twisted round, letting the thin edge from the centre (as A, Figs. 7 and 8) hold it together at the ends, as shown by the dotted lines in Fig. 7; and while held in that position, with the left hand keep tapping it gently with a hammer in the centre; this will make the wrinkles lay flat, which the thin edge will form itself into. It is sure to spring back a little, if only in drying, and it will then be its proper shape, as Fig. 7. The ends will want tapering, and the front of the whole lift as well, and then they can be put under the sole and a nail driven in at A, Fig. 6, to hold them in position. The heel can then be trimmed up, as shown in the answer to M. M. (Vol. II., page 568, No. 87).

The way to cut and lay down the channel you will see in the article I have spoken of above on "Soling," etc.

The way to sew down the heel is shown in B, Fig. 6, and how it is done is told as above in Vol. II., page 568, No. 87. And the way to finish, set up stitch, iron, etc. etc., good enough for the purpose you ask (or, any way, for your first three or four pair), you will find by searching the pages spoken of above.

To make the heels wear longer, a few nails can be put in the back, as shown in Fig. 6.

I know I have given you a lot of searching, but my experience was gained by searching for detail, and, if you can but see it, there are many more awkward corners turned in some of the above answers than I could tell you in any straightforward article, unless it was very long.

## HINTS ON NETTING.

BY LANCELOT L. HASLOPE.

This short paper was suggested by and is in reply to a query by J. H. (*West Bromwich*), as to the *modus operandi* of netting, and the tools required. For illustrations of the netting needle, mesh, mode of making stitch, etc., the reader is referred to Vol. II., page 425, otherwise No. 79.

The tools required for making nets are very simple. They consist of a needle to hold the twine or other material used, and a spool or mesh to form the loops of the net upon. They are usually made of some kind of hard wood, generally box, and can be purchased from most ironmongers and woolshops for a few pence. If J. H. could get a sight of them, he would doubtless be able to make them for himself of the exact size he requires.

The knot used in netting is the weaver's knot, or sheet bend, shown in page 65 of Work, No. 109. There are two methods of making it used by netters. The most common way is called "under edge" netting. This is easy enough when you know how to do it, but it is complicated and quite impossible to describe without the aid of elaborate illustrations. The other mode is called "over edge netting," or "braiding." As this is much simpler, I will do my best to describe it. The first thing to do is to make the "foundation." A piece of small cord or stout twine, about a yard long, is joined together at the ends with a sailor's knot and then fastened to the handle of a door or other suitable place. If the net to be made is small, the left foot may be put in the loop. The needle having been filled with twine, one end of the twine is made fast to the foundation. The spool is held in the hollow between the forefinger and thumb of the left hand, the fingers being extended along it, as a pen is held in the right hand. To form the first stitch the twine is brought over the spool, then under it, over the foundation, and up over its own part—thus forming a clove-hitch. The hitch thus formed is now held between the tip of the forefinger and the thumb of the left hand, while the needle is passed over the foundation again and up through the loop formed; the two loops are pushed close up together and hauled taut. This is repeated again and again until as many half meshes or loops are formed as are required. When this is accomplished, turn the foundation over and slip the loops off the spool; pass the needle over the spool, round under it, and bring it up through the first loop on the foundation; draw this down until the end of it just touches the upper edge of the spool; hold it there with the forefinger and thumb of the left hand. Throw the loose twine well over to the left side of the loop that has just been taken up, and pass the needle behind the loop and bring it up in front of the spool, and haul taut. The knot is now made. Pass the needle over the spool round it and up through the next loop, round the back of it, and between it and the last loop, and when hauled taut another mesh will be formed. Care must be taken to have sufficient slack twine, so that the needle has plenty of room to work easily. In every case the stitch must be made *on* the loop taken up, and not below it, or a "slip stitch" will be formed which is fatal to good netting. Braiding has some advantages over "under edge" netting. In the first place, it can be done with greater rapidity; it also makes rather a better stitch—at all events, one that can be tautened more easily. If any difficulty is experienced in making the first row of half meshes, the spool may be dispensed with, and the loops made with the fingers of the left hand alone. In mending nets, the fingers alone are generally used in the place of a spool.

## SHORT LESSONS IN WOOD-WORKING FOR AMATEURS.

BY B. A. BAXTER.

Introduction—Object in View and List of Tools Needed—Desirable Additions.

These lessons, compiled from some years' experience, are written in response to a widely expressed wish for a column in Work which should be devoted weekly to teaching carpentry in a progressive and practical manner. It is thoroughly impossible, however, to promise that the lessons shall be "continued in our next," and it is difficult to compress a lesson into a column, but something shall be attempted. This brief introduction is written to clear the ground and to explain several matters which the papers may not have made clear to a typical pupil.

Our object is to advise a beginner, who, without experience, needs guidance, to avoid errors and mistakes into which he is apt to fall. It is presumed that the learner will know the names of a few of the more general tools, and the more special tools and adjuncts will be explained as they are required.

First, a bench. There are many now in the market that are good and suitable; do not get one that is too low, and let the sort of work you intend to favour have an influence in your choice. The smaller benches sold at the tool-shops are not high enough for an adult—from 33 to 34 in. for a man is excellent, 26 to 30 in. for boys.

In a review of a book on "Slojd" (Vol. III., page 330), the Editor recommends benches made with screw at the end as an excellent addition to the bench. I quite agree with him, and advise all who can do so to obtain a bench so fitted.

The tools necessary are dependent upon many considerations, but those which follow may be regarded as indispensable:—

Planes: A jack-plane, 17 in. long; a smoothing-plane; both 2¼ in. iron.

Saws: A hand saw, 26 in. long; a panel saw, smaller teeth, ditto; a "carcase" dovetail saw, 10 in. or 12 in.; a bow or frame saw, 12 in. blade.

Chisels: A set of eight, "firmers" and

assorted. For mortise chisels, obtain $\frac{5}{16}$ and $\frac{7}{16}$ in. sash chisels.

Gouges: Three or four, chosen to taste, $\frac{3}{8}$ in. upwards.

Gauges: Two marking and two cutting and one mortise gauges; a 2 ft. rule, one $4\frac{1}{2}$ in. square, one 9 in. or 12 in. square; hammer, mallet, a few bradawls, one pair of dividers, a bevel, two screwdrivers, two punches, an oil-stone, oil-stone slip, and oil-can; for fixing work, two or three hand-screws and glue-pot; if hard wood is to be worked, a scraper and a toothing-plane. If funds are still in hand, buy an iron stock or brace, and a selection of boring bits, a spokeshave for curved work, a spirit-level, and pair of pincers. When the use of a jack-plane is acquired, and freedom can be combined with definite stroke, well under the operator's control, a trying plane may be purchased, but it is useless without this preliminary practice.

There are several accessories which may and ought to be made by the amateur, such as bench hook, mitre cut, shooting board, etc. Explanations of all these have been given in WORK, and the index may be consulted to great advantage. In our first lesson we shall consider the plane.

## SQUARE AND OBLONG VESSELS IN SHEET METAL.

BY R. ALEXANDER.

SQUARE AND OBLONG-SHAPED ARTICLES—HOW TO MARK OUT AND MAKE UP—EXAMPLES—SQUARE VESSELS WITH UPRIGHT SIDES—DITTO WITH SLOPING SIDES—YORKSHIRE PUDDING PANS, DOUBLE BAKING PANS, BREAD TINS, AND SIMILAR ARTICLES.

A FEW simple examples of square and oblong work will now be given. To make a rectangular vessel with upright sides and of given dimensions, sides and bottom in one piece (Fig. 1), let the size of the vessel be, for example, 8 in. by 5 in. by 2 in. In this case add twice the depth of one side to the length and also to the width; this gives the size of the piece of stuff to cut it out of. I am supposing this to be a plain tin pan without wire or fold. Thus the size in this case will be 12 in. by 9 in. Mark out a square of that size on the metal, A B C D, Fig. 2. With compasses set at the depth required, place one point at the corners successively and mark the eight points × and draw lines through them parallel to the outside lines; this will be the line to fold the sides up from. If the sides are to be simply soldered up, the corner pieces of the pattern must be cut out; if it is to be lapped round at the ends, leave pieces as shown by the dotted lines. If the pan is to be wired, allow as much extra as will be required for the size wire to be used, parallel to the outside edges (see dotted lines). It will be found that wiring makes the article larger in its outside dimensions, though not in its capacity—by twice the thickness of the wire and of the tin that covers it. Thus, in the example just given, instead of the vessel being 8 in. by 5 in., it would be $8\frac{1}{4}$ in. by $5\frac{1}{4}$ in. So if an article of this description is to be made of a given dimension *outside* the wire, the bottom must be marked as much smaller all round as the thickness of the wire to be used, and a trifle more even, to allow for the thickness of the tin. When the article is to be larger at the top than at the bottom, it is cut out like Fig. 3, which we will suppose to be a pattern for an article the same size at the bottom and same depth of sides, but 1 in. larger each way at the top. After marking the corners out square as in the previous example, set the compasses to half the size larger required at the top, and from the points A, A, B, B, C, C, and D, D, mark off points E, E, F, F, G, G, H, H; draw lines from these points to the corners × and you have the required pattern. Oil tanks for paraffin stoves are made like this, only then the part we have been calling the bottom would be the top, and the bottom would be soldered in at the large part.

*Yorkshire Pudding Pans* (Fig. 5).—The pattern for these and the method of marking out is shown at Fig. 4, which is a full-size pattern of a corner; for stock sizes they are usually cut full out of the stuff (after squaring up), single, middle, and double, and are turned up from $1\frac{1}{2}$ in. to $1\frac{3}{4}$ in. (before wiring). It is marked out in a similar way to Fig. 1, but after marking the points, which give the difference in size between the top and the bottom, a line is marked for cutting the notch to allow for wiring; this notch is cut down rather deeper than twice the diameter of the wire to be used. The dotted line, A B, shows the idea. The compasses are then placed at the corners with radius × A, and the arc A C described. The portion F is then cut away; the other corners are, of course, treated the same. In working up, great care must be taken with the corners to get them true. I will try to describe the way to do it. Press the corners over the tip of the extinguisher stake and bend on the line E ×; this will commence the corners and slightly turn up the side. The bending of the sides can then be continued on the hatchet stake; or, if that is too wide, on the side of the anvil or end of crease iron, assisted by the mallet. When the sides are up sufficiently the corners are knocked together, A and C meeting, and bent round on the ends of the article, against which they should lay quite close and flat; the sides are then finished. The dishes can next be folded for wiring on the hatchet, wired and jennied, which completes them, as they require no solder when turned up in this way.

There is a tool called a dripping-pan swage, which will turn up the sides; it can be set to various depths, and is very useful for piece-work. Whilst on the subject of baking pans or dishes, a word or two on making dishes to order may not be out of place. In these there is usually a given size, and it is generally the length and width of the top and the depth; it is very seldom that the dimensions at bottom are given, that is left to the judgment of the workman. I have already shown how these dimensions may be regulated, and would draw attention again to the fact that allowance must be made for the wire, or the dish would be larger than the dimensions given. Always err a little on the safe side; thus, if a dish is ordered 12 in. by 10 in., try and work to get it $\frac{1}{8}$ in. under each way, there can then be no dispute about its being too large to go in the oven, and the slight difference in the measurement is of no practical importance in a case like this. A frequently occurring order is a double baking dish (Fig. 6). The bottom dish is a plain dish to contain water only; the inner dish that contains the meat has a well, strainer, and filling corner. The outer dish is made with more upright sides than would be the case if it were a single dish, and also somewhat deeper; 3 in. deep is a usual size for dishes of over 12 in. square. The inner pan must be cut about $\frac{3}{4}$ in. smaller each way, as it will not want to be so deep; but it must be the same distance along the sides after the notches are cut. Fig. 7 illustrates what I mean; if this is carefully attended to, the dishes, when turned up and wired, will fit each other nicely. With regard to the well, it can be hollowed in either before turning up or after; for myself, I prefer to put it in after wiring. A circle should be described in one corner so that its circumference comes about $\frac{1}{2}$ in. from each side of the dish. (See Fig. 8.) To hollow up the well, I wire a strong piece of tin with a small wire (about No. 13) and turn it round and seam it together, making a neat join of the seam at the wire, and also solder round the wire, then solder this on to a piece of tin about 1 in. larger all round; punch two or three small holes in this, and tack it to the bench with some tin tacks; place the dish over this, and work gently all over the circle described for the well, commencing in the centre. This is a much better way than hollowing on the block. Of course, care must be exercised in hollowing not to push it too far, or the stuff would split and spoil the dish. A strainer should be put in the corner where the well is, so that the gravy can be strained as it is poured out of the dish. Fig. 9 shows this. It will be seen that the angle of it is greater than a right angle; this is so, that when it is fitted to the corner of the dish, the front of it will be raised above the level of the dish. Close in the opposite corner of the bottom of the inner dish a $\frac{1}{2}$ in. hole must be punched and a plain piece of tin soldered and riveted across this corner marked A. Fig. 6 is for pouring water into the outer dish, so the reader will see that the piece of tin which covers the hole must be quite sound or the water would get into the inner dish. A pair of handles is affixed to each dish, and as this kind of handle is frequently required for many other purposes, I will briefly describe how to make it.

Fig. 10 shows a very handy tool for bending the wire into the shape required. A piece of wire of the required length is placed between the two pairs of rollers as shown in the figure; the handles, H, H, being pulled apart, the wheels at their extremity travel round the semi-circles and bend the wire into the shape shown at F. This is a most useful tool where a quantity of such things are wanted. Failing this tool, they can be bent on the extinguisher stake or in the vice by means of an improvised tool consisting of a piece of $\frac{1}{2}$ in. or $\frac{5}{8}$ in. round iron bent into the shape of a U. (See Fig. 11.) A strip of tin of sufficient width is then passed through the handles and bent over the join in the wire (which is rather a bull considering that there is no join, so let us say where the wire meets); it is then laid on the edge of a tool and knocked close, the wire sunk all to one side.

Fig. 12, A, B, C, shows these details. The handles of the outer dish are fixed on the outside, and those of the inner dish on the inside; two rivets must be put through each; a pair of wire runners are generally, though not always, fixed to the outer pan to prevent the bottom wearing out through drawing in and out of the oven. The meat-stands for these dishes are usually kept in stock; if not, the smith makes them. If I had no smith, and could not get a stand, I should make one myself.

*Square Articles with the Sides and Bottoms in Separate Pieces.*—Example, bread tins (Fig. 13). To mark out the end pattern, set out a line, A B, Fig. 14, and draw another line parallel to it at a distance

equal to the depth required, and draw E F perpendicular to them from E on line A B. Set off on each side of the perpendicular line a distance equal to half the size required at the bottom of the tin × × and on line C D. From the point F set off each side half the size required at top of tin, Y Y. Join Y × on each side of the perpendicular line and you have the pattern perfectly true and correct. The pattern for the side, Fig. 15, is drawn in exactly the same way. Allowance for seam-wiring and edge for bottom should be added on to the pattern after marking what I will term the net size. I have marked it on the side pattern, Fig. 15, by dotted lines. The end pattern will require the same allowance as the sides for wire and bottom edge; but at the sides only half as much. The reason for this is that as the sides are knocked round on to the ends, there is a double turn on the side portion, thus requiring a large notch. Of course, if the ends were to be knocked on to the sides, the side pattern would have the small notch and the ends the large one. This kind of article is very easy to make. After cutting out, place all the pieces, sides and end, with notches all one way, at the folding machine. Fold the sides first, about the same size as for a saucepan, and seam and fold them right close up, both folds one way. (See section line of fold, Fig. 19, A.) Next fold the ends, but instead of folding close as in the case of the sides, fold just over a right angle. (See section line, Fig. 19, B.) After folding thus, fold for wiring. The ends must be put into the machine with the fold *uppermost*, and the sides with the fold downwards, or they will not come right when put together. If you are very sure that your cutting out is absolutely true, the edge for the bottoms can also be folded in the machine; but it will be best at starting to throw off the edge after they are put together and wired. The way to do this is to put them together in halves first—that is, take a side and end, and slipping the side into the end, and keeping it in position with

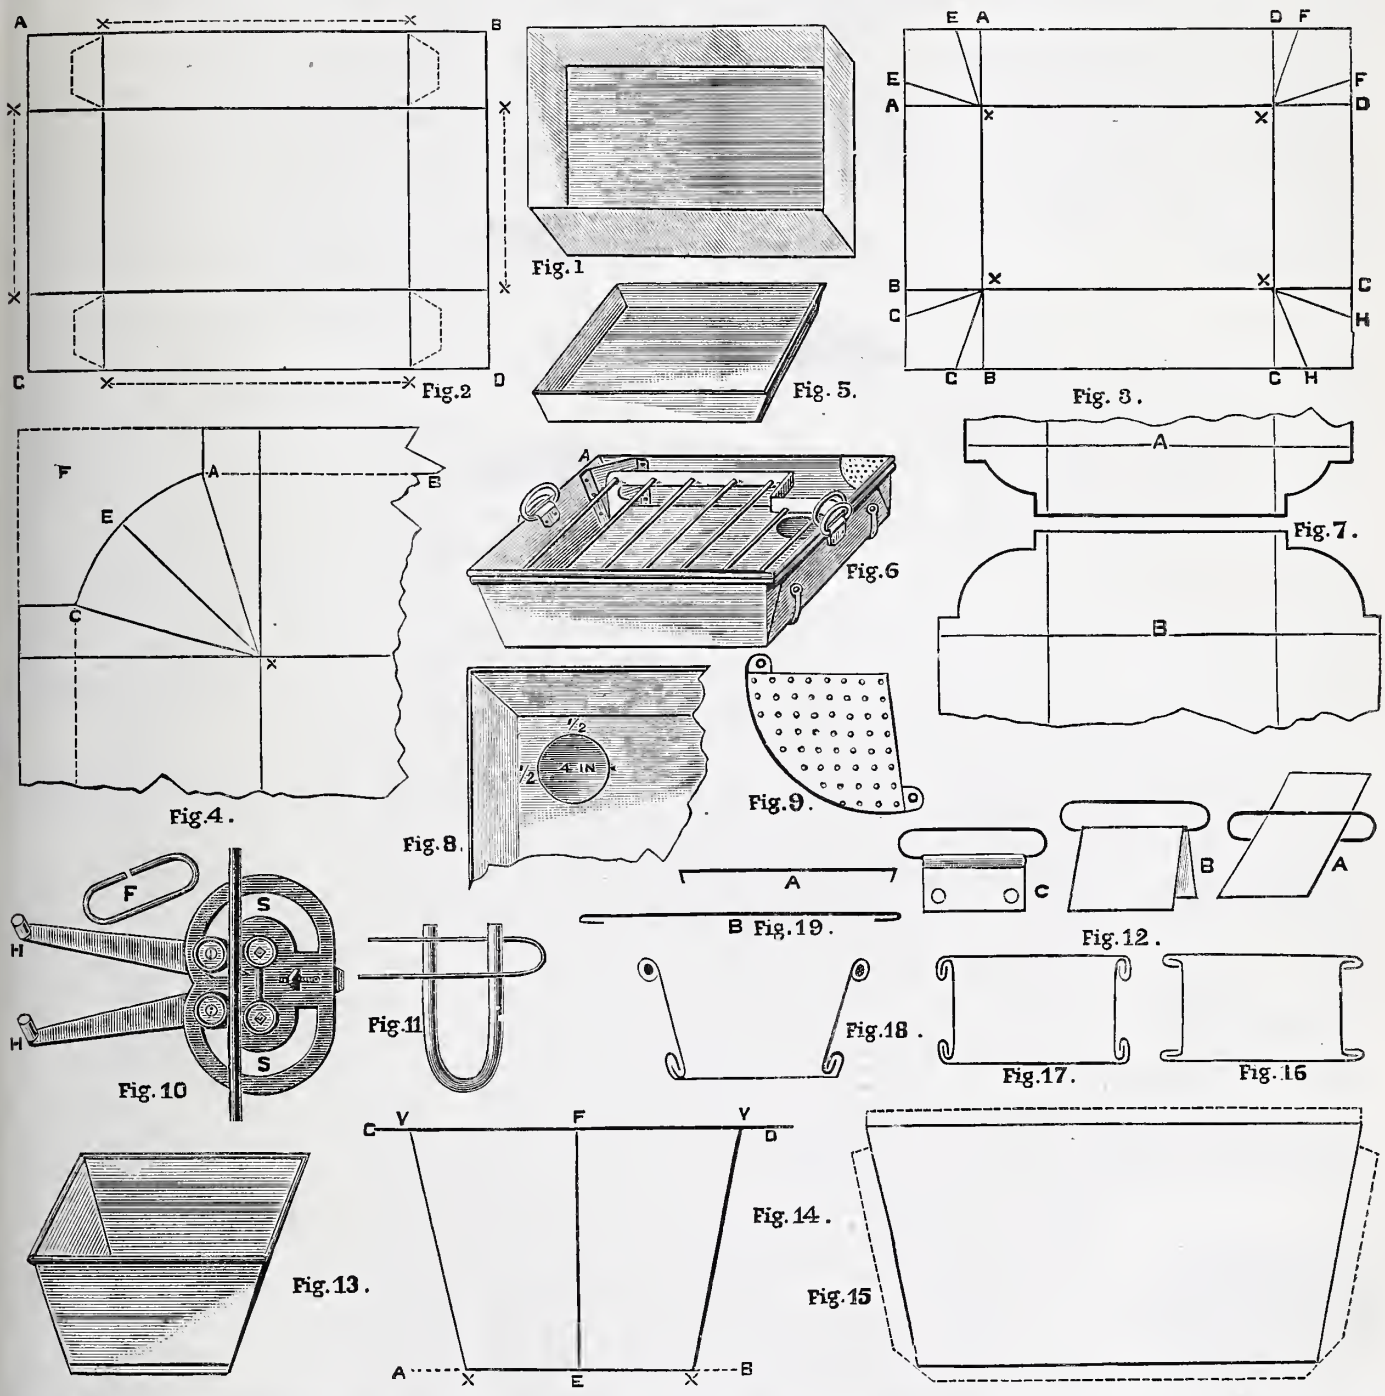

Fig. 1.—Rectangu'ar Upright-sided Vessel. Fig. 2.—Pattern for ditto. Fig. 3.—Rectangular Sloping-sided Vessel. Fig. 4.—Full-size Pattern of Corner of Yorkshire Pudding Pan. Fig. 5.—Yorkshire Pudding Pan. Fig. 6.—Double Baking Pan. Fig. 7.—Comparison between Inner Pan (A) and Outer Pan (B). Fig. 8.—Diagram showing Position of Well. Fig. 9.—Strainer. Fig. 10.—Wire Handle Former. Fig. 11.—Home-made Tool for bending Wire, etc. Fig. 12.—A, B, C, Detail of Handles. Fig. 13.—Bread Tin. Fig. 14.—Pattern of End. Fig. 15.—Pattern of Side. Figs. 16, 17.—Cross Sections of Bread Tin, showing Seam. Fig. 18.—Section of ditto, showing "Knocking up." Fig. 19.—Section Lines, showing folding of Ends (A) and Sides (B).

the forefinger, pane them together; use a bick-iron for this; then knock this seam down on the end. It will be found that this leaves rather a rounding edge. To square this up, hold the seam edgeways on the bick-iron and go along the rounding edge with a square-faced hammer; do them all like this, and then put the halves together in the same way.

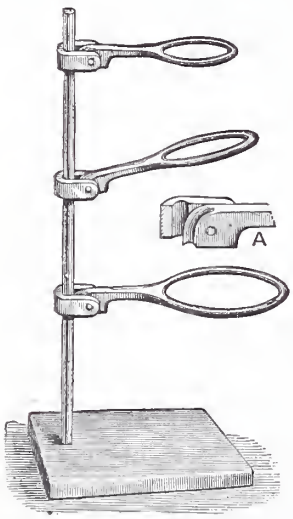
Figs. 16 and 17 are cross-sections of the tin, showing seams paned and "knocked up." Next wire them and edge for bottoms, cut bottoms with sufficient allowance for turn up, notch all four corners off, turn up on the hatchet, and pane and knock up as usual. Square the knocking up with the hammer in a similar manner to that described above. Fig. 18 is a section showing seaming of bottom.

## OUR GUIDE TO GOOD THINGS.

**** Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

### 83.—Moor's Self-locking Retort Stand.

The Self-locking Retort Stand shown in the accompanying illustration is the invention of Mr. C. G. Moor, B.A., who has produced other useful appliances for chemical and other work, among which may be named his Chromic Acid Battery, a cheap and powerful battery for laboratory work, his "Simplex" Gas Generator, and his new Mouth Blowpipe, well adapted for the purposes of analysts, dentists, jewellers, etc. The form and construction of this new pattern retort stand will be easily understood from the annexed illustration; and the enlarged view of the locking portion of the apparatus at A, in which the portion of the slide nearest the spectator is removed in order to show how the inner end of the arm which holds the ring acts against the rod on which it slides so as to render it immovable in the position in which it is placed until there is occasion to alter it. Thus it will be readily understood that the ring can be adjusted to any height required in a moment by raising the ring slightly, and then sliding it up or down as required. When the ring is pressed down the arm and ring will automatically lock and remain perfectly steady. It is claimed by the inventor that this retort stand possesses the following advantages over the ordinary form: (1) When hot, the rings are easily moved by lifting them with the end of a file or other similar iron tool. (2) In the old form, if made of brass, the thread of the screw is apt to wear out and slide; whereas, if the set-screw is made of iron, the acid vapours of the laboratory will soon rust the thread, and make it difficult or impossible to use. The rings in this Self-locking Retort Stand are made of cast iron, and carefully annealed by a new process: this renders them very strong, and as they are of considerable thickness, no fear of burning away the metal need be entertained, as a Bunsen flame may be directed on them for any length of time without the slightest detrimental effect. The sole manufacturer is Mr. James J. Hicks, but I presume they may be obtained of or through any dealer in druggists' sundries.



Self-locking Retort Stand.

### 84.—The "Vulcan" for Pyrography or Poker Work.

What is popularly known—or it would be better to say what *was* popularly known—as "poker work," was a rough semblance to a landscape or portrait by exposing the surface of a piece of wood, jointed and prepared for the purpose, if on a large scale, to the action of heat emanating from the end of a poker or similar piece of iron heated to redness. The drawings, if they may be so called, were very coarse and rough in appearance, but of late years far more pleasing and attractive decorative effects have been obtained by the use of tools which are far lighter and more convenient to handle than the cumbrous poker, which it was always difficult to keep at the proper heat for the purpose in view. These tools have been specially designed for the work, and are supplied by Messrs. Abbott Brothers, whose advertisement will be found elsewhere in this number of Work. The apparatus is supplied complete in a box, and consists of a stoppered benzoline bottle, an extra store bottle, a metal attachment or union, a spirit lamp, an indiarubber bellows with tube attached, an extra piece of tube, a small funnel, a metal pencil cased in cork, a light pencil for ladies' use, a platinum point, two small panels, and a sheet of designs. Platinum points of different forms are supplied, some of which are shown in the accompanying illustration, and are adapted for tracing lines of different breadths, and thus producing varied effects. The spirit lamp, to be used for heating the platinum points, is first lighted, and the indiarubber tubing properly adjusted to the bottle containing benzoline and bellows, after which the platinum point to be used is heated to redness in the flame of the lamp, which is then blown out, for the heat of the point is said to be then maintained and brought to a greater or less degree, as may be required, by blowing with the bellows more or less quickly on the point, which, by this means, is kept in a proper state of adjustment to produce the depth of tint required. The design to be executed with the platinum point should first be traced on the wood with the pencil before the hot point is used. After a little practice there is no doubt that the work can be easily and quickly executed, and that pleasing effects can be produced. Most of the white wood fancy articles now so much in request can be artistically decorated by pyrography. With the apparatus—which consisted of the articles above-mentioned, complete in a neat box—Messrs. Abbott Brothers submitted for inspection a stand for a small drum clock or watch, worked in a pattern with the hot point, which presented a variety of rich tints combining, with the dark lines of the pattern itself, to produce an article that would be highly appreciated at bazaars, etc. The Editor.

## SUGGESTIONS FOR WORKERS AND HINTS TO INVENTORS.

Commercial Electrolysis. — Electricity is beginning to play so important a part in many processes for the commercial production of various articles, that a large number of inventors have, of late, turned their attention to the subject. Soda and similar products, as well as many of the metals, have been the subjects of experiment, but no very marked success has hitherto been achieved. As, however, it is generally admitted that a large fortune may be made by anyone lucky enough to discover an effective process, the efforts in question are not likely to be abandoned. Unfortunately, a good many people devote their attention to such subjects who have no thorough knowledge of either chemical or electrical matters, and an expert qualified to write a work upon the subject would find it a profitable undertaking.

Mechanical Voting.—One does not generally look to the pages of *Truth* for hints as to new inventions, but "exceptions prove the rule." Its editor points out in a recent issue that ninety-two hours were wasted last session in Parliament in the mechanical business of taking divisions, and suggests that some inventive genius might devise a more expeditious means of arriving at the desired end. Except by fitting a pair of electrical pushes—"Aye" and "No"—to each member's seat, we do not, however, well see in what way mechanical aid could be given. It might perhaps be possible to devise a dial-pointer which the voter could place in such a position as to record his vote on a current being passed through the entire series, an indicator near the Speaker's chair showing a total of so many "Ayes" and so many "Noes." There should be no great difficulty in devising something in this way if it was likely to be adopted by the House.

Phonographic Advertising.—The man who first of all avails himself of the phonograph to advertise his wares will, in all probability, distance all competitors—at all events, for a time. The novelty of substituting the ear for the eye would undoubtedly "catch on." A machine which continuously reminded the passer-by that he "ought to buy Smith's soap" would attract the most careless attention. Still more would a combination of eye and ear be likely to succeed. A life-sized face, from the lips of which the sentence could be heard, would beat anything yet in the field. The chief disadvantage would probably be that it would be too popular, and that crowds might assemble to watch the new departure to so embarrassing an extent as to necessitate police interference.

Removing Ink Blots.—An easy way of removing a disfiguring blot upon paper is not by any means generally known. The knife and rubber ink-eraser are usually resorted to, with the result of spoiling the surface of the paper. People liable to such accidents will find it useful to take a few sheets of thick white blotting-paper, and to steep them three or four times in a solution of oxalate of potassium or oxalic acid, letting them dry between each steeping. This applied to a damp ink spot will at once remove it. If dry, the spot should be wetted, and allowed to remain in that condition for some little time. The prepared blotter will then, as a rule, remove it; but in cases where the ink has been allowed to dry into the fibre of the paper, success cannot be guaranteed. With a fresh blot, however, it is always successful.

Drilling Glass or Porcelain.—Amongst things not generally known is the fact that, when it is desired to drill glass or porcelain, it is well to touch the place of the hole with hydrofluoric acid before applying the drill. This roughens the surface, and allows the point to "bite." Many people, also, are not aware that the glaze of porcelain is the substance that presents the hardest surface, and that when this has been penetrated, the boring proceeds easily enough. A hole should never be drilled right through from one side only. Directly the point of the

drill shows, the tool should be applied to the tiny orifice, and the hole cut clean in this way. Paraffin oil is a good substance for aiding progress. If the hole is too small, it is better to ream it out with a piece of tapering. four-sided steel than to use a larger drill.

## SHOP:

### A Corner for Those who Want to Talk It.

*** *In consequence of the great pressure upon the "Shop" columns of* Work, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—Letters from Correspondents.

**A Simple Cramp.**—J. W. writes:—"Seeing in a recent number of Work that one of the readers had been asking for a contrivance for holding the joints of mitred frames, I thought the following simple cramp might be useful to some of the amateur readers who do not care to go to the expense of buying a proper cramp:—Plane a piece of deal, 2 in. by 8 in. by 1 in., up true, and two pieces about 1 in. long by 2 in. by ⅝ in.; screw these on the large piece at an angle of 45° with the long sides, so that they form a right angle with each other, but leaving the inside corner about 5 in. apart, as shown by A and A', Fig. 1, which is drawn to scale, as shown below. Now plane a piece of ⅝ in. stuff up, of the shape shown at B, Fig. 1, and screw it in place as shown. Now cut two wedges out of ⅝ in. hard wood, 9 in. long, and about 3 in. wide at the broad end, with a notch cut in as shown at Fig. 2. These

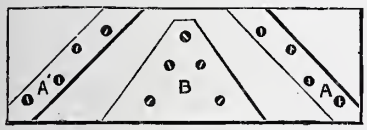

Fig. 1

Fig. 2

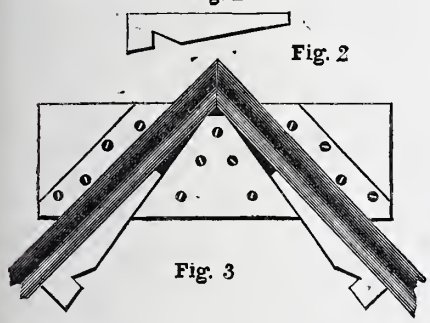

Fig. 3

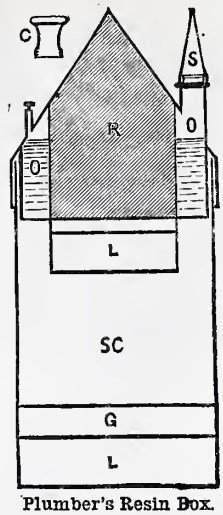
**A Simple Cramp. For Explanation of Figs., see accompanying description.**

are cut out of thin stuff to allow them to slip under the front edge into the rebate. The way of using it is shown in Fig. 3: one side should be fastened in place first, then glue the joint and place the other side in position, driving the wedges in quite tight. The joint may now be fastened by running a sawgait in and gluing a piece of veneer in, or by screwing with fine screws. Now knock the wedges out, and treat the other corners in the same way. This will be found to be a very handy method, and a good deal less cumbrous than the one given in answer to the above reader, which will be found on page 229, No. 123. One man that I know well, who has made some dozens of frames of all sorts, never uses anything else. Another thing that I may say is that he always uses fine screws. Brads do not answer very well, as the wedges want driving so tight, it is apt to injure the frame if it is at all delicate."

**"Robinson" Air Engine.**—E. E. P. (*Tufnell Park*) writes:—"I notice a reply to a query respecting a motive power for organ-blowing in Work No. 132, page 446, column 1. The 'Robinson' air engine is particularly suitable for this work, being inexpensive, and costing but a trifle to work. Messrs. Morris & Henty are making these engines."

**Plumber's Resin Box.**—Reader of "Work" writes:—"I have drawn a plan for a combination plumber's resin box, which I have found very handy. It contains oil (O), resin (R), place for screws (SC), etc., and grease (G) in the bottom. I did not know if it would be of use to anyone else. The oil runs round the resin box; the resin box and oil are in one. The resin box has a lid (L) at the bottom; the spout (S) unscrews when not wanted, and the cap (C) screws on. Put the spout in with the screws. At the bottom I have parted it off about 1 in. and put on a lid (L) for grease; this is full size, and made of tin."



**Plumber's Resin Box.**

**Pocket Accumulator.**—E. R. D. (*Sherborne*) writes, in reference to reply to S. G. V. (*Boro'*) under this heading in page 443, that he "should see the portable lamp illustrated in a recent number of the *English Mechanic*. If preferred, the lamp can be made to take off, and used at a distance from the accumulator."

### II.—Questions Answered by Editor and Staff.

**Clock Cleaning.**—J. A. (*Inverness*).—Any watchmaker would be able to let you have one or two second-hand movements—lever would be best, or heavy Genève—as when buying the cases the works are usually taken out; this would be the cheapest way to go to work. Failing to get what you want like that, apply to J. Crewe, 100, Aldersgate Street, London, E.C., or W. Cardall, Ombersley Road, Droitwich, who keep good movements; but, of coursc, you would have to pay much more for them. If not able to find what you want, write to any watch tool shop and try them.—A. B. C.

**Wheels for Wire-crimping Machine.**—W. G. (*Glasgow*).—For the required set of cog-wheels, the firm most likely to suit you is the Phosphor Bronze Company, Ltd., 87, Sumner Street, Southwark, London, S.E. It seems that you must tender a pattern or patterns in wood (or wax, from which wooden ones will be made) from which to cast the wheels. You must obtain the assistance of some friendly wire-worker who owns a machine. I advise you to write to the above company, alluding to this reply, when, doubtless, you will receive duel and courteous attention.—J. S.

**Squeaking of Bearing.**—A. McD. (*Glasgow*).—If the bearing is properly cleaned out and oiled, there will be no squeaking sound there. Perhaps it is some other part of the machine that gives forth the squeaking sound. If after cleaning out the bearing with paraffin, and oiling up properly, the sound is still heard, look for it somewhere else than in that wheel. Perhaps the rim touches some part of the frame at every revolution, or perhaps the pedal nut touches the chain or a stay rod.—A. S. P.

**Cups for Bicycle Bearings.**—J. B. (*Clapham*).—Cups for bearings are usually casc-hardened before putting into their places. But as the process is both tedious and expensive, another method of hardening may be followed. Have the cups fitted in the hub-ends, then take them out. To harden them, get prussiate of potash, pound it down to a powder, and heat the cup to a red, not white, heat; sprinkle the powder all round the hollow in the cup, where the balls run; the powder will fizzle for a minute or so, then reheat the cup to a dull red, and plunge into cold water. The acid will have penetrated the metal, not through, but of a sufficient depth to make a very hard surface for the balls. The size of balls will depend entirely on the size of cups. For pedals, $\frac{3}{16}$ in. balls; for wheels, ¼ in.; for bottom brackets, $\frac{5}{16}$ in.—A. S. P.

**Price's Lathe with Vertical Slide.**—G. H. (*St. Helens*).—R. Price's address is now 125, Stratford Road, West Ham, E. The lathes will do turning, boring, milling, slotting, shaping, and wheel-cutting. Ordinary lathes will do all these, but the vertical slide gives especial facilities for milling, boring, shaping, and wheel-cutting. For milling and boring with the bar, the vertical slide is so convenient that it is a wonder those who have no milling machine can be content to do without it. It is not pleasant to do much wood-turning on a lathe intended for metal, but if you wish to do this, you might fix up wooden bars so as to continue the bed three or four feet and take the poppet and hand rest, but *not* the slide rest, which you don't want for turning wood; it would only be in the way. Mr. Price says he has made one with a gap, so I suppose you can have one if you wish. I think the watch lathe mandrel would not "jamb," but drive rather hard in drilling if made as you propose.—F. A. M.

**Taper Hole in Mandrel.**—Oliver asking More.—The taper of hole in mandrel used by Britannia Co. is 1 to 9; Milnes used formerly 1 to 12, but now he has adopted the Morse taper, and I think you had better do the same. You can't get the right taper by setting the slide-rest by the quadrant, that method is not sufficiently exact. I advise you to buy a little American drill chuck (sure to be useful) fitted on a Morse taper plug of the proper size to fit inside your mandrel nose; then bore the hole with a drill to the size of the small end of the taper plug, fix a sharp tool in the slide-rest, and, setting the cutting point at exactly the height of centres, gradually turn out the hole till the plug fits and your little drill chuck runs true. You must rub a little red marking on the plug and squeeze it into the hole; notice where the red is rubbed off, and adjust the slide-rest accordingly; the last cut should be taken with a very sharp tool and a fine feed.—F. A. M.

**Fitting Fly-wheel.**—Oliver asking More.—If the hole in your fly-wheel is ⅛ in. larger than the shaft on which it is to fit, I should either bore out the hole ⅛ in. larger, or turn down the seating on the shaft ⅛ in. smaller, so that there might be a space of ⅛ in. all round between the two; then get a piece of steam-pipe, bore it out to fit on the shaft, drive it on a mandrel, and turn the outside till it fits into the wheel; now take a hack-saw and cut right through one side of this piece of pipe. Now, if you have a keyway in your wheel, you will file a flat on the pipe at 90 deg. (or one ¼ round) from the slit, so that the key can collapse the pipe on shaft; if there is a set-screw in the wheel, it will bear on the flat on the pipe and compress it in a similar way.—F. A. M.

**Gauges.**—A. F. should write to Messrs. Sharp, Stewart & Co., Glasgow.—F. C.

**Motion.**—A. U. S. (*Birmingham*).—Your design will work very well with a few additions. The lower roller should have a light recovery spring. To maintain continuous motion you will require a fly-wheel on the axis of disc. If you will send particulars of the purpose to which you propose to apply this motion, I will give you full instruction in the matter.—F. C.

**Spindle.**—A Working Man.—Any local smith can supply you with the spring and spindle. I should think 2s. for the spring, and 1s. for the spindle would be enough.—J.

**Coach Painting.**—C. C. (*Milford*).—In the first place you want a paint-mill to grind your colours fine; such colours as Prussian blue, Dutch pink, Vandyke brown are as hard as stones. After being crushed up with a hammer they can be ground quite fine in a hand paint-mill, the cost of which will be 30s., and I am sure that you will never regret buying one. But such colours as ultramarine, green, or vermilion and brown, which you mention in your letter, should cause you no trouble in grinding fine upon a slab with the muller, as these colours are generally sold in the powder and not in little lumps as the above-mentioned hard ones. After grinding the colour upon the stone you had better let it run through a sieve or muslin. I fear that it is not the paint which is gritty, there are other things besides, such as having the room perfectly clean, using clean and separate brushes, no draughts to create a dust, etc. As you have not mentioned what it is you are wishing to paint, I will just merely show you how to mix and lay the colour on. In painting with ultramarine it is usual to give a preparation coat of Prussian blue, but as a substitute, and which will do equally as well, get some ultramarine and a little drop black and grind in gold-size and turps; get this on the panels as soon as possible, as it soon sets, and will show brush marks, besides going thick in the pot. In painting the wheels, finish off three spokes at a time; be handy in putting this dead colour on, and do not work it about much or you will have it cordy. Next get some ultramarine ground in turps, gold-size, and varnish, and give another coat; the colour which is left can be made into varnish colour by adding sufficient varnish to finish the job. This is put on when the first coat of ultramarine is dry, which will take from six to twenty-four hours, according to the quantity of varnish added. When painting the ultramarine, see that it is solid and not cloudy; when dry, and before varnishing, it should be flatted to smooth it down a little. In painting vermilion, colour all the parts which are to be red with a couple of coats of pure white lead; when this is quite dry, mix the vermilion in its pure state with gold-size and turps, and give it a coat of this dead colour. When dry, grind some more in boiled oil with a little liquid driers and finish with an oil coat of vermilion, as the colour will remain purer longer than if varnish had been added to it. In the case of blue and brown oil must not be added. Picking-out colours can be mixed dead or in oil; in dead colours the colour is simply ground in gold-size and turps, and the work can be varnished the same day. In fine-lining with oil colours these can be bought ready ground, and far purer than you could grind them, in tubes at any artist's colourman, the price ranging from 3d. to 6d. each; the dark colours can be mixed with dark gold-size, but the lighter colours must have a paler varnish added to it to help in drying. It can be varnished over the day after. Papers on coach painting are in preparation, and will appear as soon as room is found for them; do not be afraid of asking any questions, as hitherto coach painting has been a mystery, and still is, to a great many. "Coach Painting, by Arlot, is 6s., and Boag's "Guide to Coach Painting" is, now it is published, 12s. 6d.; if too much, wait until practical papers appear upon coach painting.—W. P.

**Van Painting.**—Wright.—You do not state in your letter the kind of brown you wish the van to be painted in, as there are a great many varieties of

browns, ranging from the dark vandyke up to the bright crimson lake, this last-named but expensive colour being merely a glazing colour, and does not possess much body, therefore, the under coats have to be finished in colour to match as near as possible the finishing coat of lake. If the van be a new one, paint and fill the woodwork up as directed in "Shop," No. 65, page 209, and the last coat of lead colour must be made up very dark so as to make the after coats look solid. Commence by giving the top, back, and side quarters a coat of dead black; when dry (in a few hours), give it a coat of black japan. If the japan sets too quick, so that you cannot work it about, add a little varnish or a drop or two of boiled oil—not too much, or it will never dry. The next day we begin to colour the carriage work and the panels; if the common browns are used, we can get any shade from light snuff to dark plum or chocolate by mixing the following: burnt sienna, raw sienna, umber, black, yellow and orange chrome; by mixing one or two of these colours you can get a distinct colour. This powder colour must be ground in gold-size and turps only, and will, when painted, dry in a few hours. Get a pot and place some of the colour in it, and after the dead colour is dry on the van, we put sufficient varnish to the colour in the pot to give it another coat of varnish colour; this last coat is merely a glaze, but should have sufficient body in it to cover. If, however, a lake is required (and it is generally used on vans), we first give it a coat of imitation lake composed of rose-pink and Indian red ground in turps, boiled oil, and liquid driers; the next day grind the crimson or purple lake very fine in gold-size and turps, and give it a coat of lake, afterwards finishing in varnish colour; leave for a few days to dry, then rub the mouldings level with stone and pick them out black, first with dead black, second with black japan. Next flat the whole of it down with a wet cloth and pumice-stone powder, doing a little at a time, and washing each piece off well and wiping it dry, or the water will stain. We then pick the wheels, springs, and shafts out with dead black; when dry, give the van and carriage work a coat of varnish; leave for a week if possible to dry, then flat or scour the varnish down again. It is now ready for picking out or fine lining; we therefore edge the black with a fine line of vermilion, lemon or yellow chrome, or pick it out with a quarter line of vermilion in the centre of two fine lines of white, or there can be centre and fine lines of red according to taste. The inside of the van will be painted light buff. The reason why varnish is flatted with powdered pumice-stone wet is to get it smooth and dull so that the last coat of varnish will flow out and not cess, as it certainly would if not flatted. When the fine-lining has been done and quite dry, we varnish the body and carriage work in a warm room well ventilated at the top and free from draughts, keeping the heat at a temperature from 65 to 70 deg. until the varnish is set and dry.—W. P.

**Cornish Valve.**—B. W. W. B. (*Whaley Bridge*).—Unless you give more particulars I cannot tell whether the valve is to act as an admission valve to the steam casing merely, or in place of slide valves. And what of cylinder dimensions, steam pressure, etc.? 20 h.-p. may mean anything. But if you know what volume of steam has to pass through the valve at each lift, you can deduce diameter from that. When the lift of the valve is one-fourth the diameter, it is fully open. There are sketches of some Cornish valves in WORK, Vol. I., page 513, though forms are modified. If you give fuller particulars, I will sketch out a suitably proportioned valve.—J.

**Watch Parts.**—C. A. B. (*London, E.*).—Screw Ferrules.—For ordinary work you might manage with about three screw ferrules; one large, about ¼ in. diam., one $\frac{5}{16}$ in., and one ⅛ in. These are generally made in two pieces to hold the pinions, etc. You merely unscrew the two screws, and pass the pinion, or whatever you wish to turn, between the two halves and screw up tight; file up a centre on each end, and begin the turning. Wax ferrules are simply thin brass or ivory with a hole in the centre and a groove turned on its edge. The article (pinion or cylinder) being filled with sealing wax, the ferrule is made slightly warm (and the waxed article too) and dropped over the pinion or cylinder and held in place till cool; then commence turning as with screw ferrule. Wax ferrules are used on very short or awkward pieces where you cannot put a screw ferrule. Bows.—Gut is used for large work and ferrules, and horse hair for small work and ferrules where gut will not go. For turning a Geneva centre pinion, get a piece of round steel wire larger than the hole in pinion, run a centre on each end, then harden and temper to a purple colour; broach out the hole in pinion till the old set hands arbor fits it nicely. Now turn the piece of wire you tempered down to fit the hole (having previously, of course, put on a screw ferrule), and see that it fits nicely all the way through the pinion, then proceed as if it were a solid pinion. I shall be pleased to advise further if necessary.—A. B. C.

**Fret Machine.**—T. W. R. (*Kendal*).—The idea of the fret machine which you suggest seems feasible enough, but there are several details which will have to be modified considerably if your sewing-machine stand is only of the ordinary light description. In saying this, it must be understood that these points can only be determined by actual experiments, which, of course, I cannot undertake to make. One of the chief modifications which seems necessary is the distance at which you purpose placing the pin on the wheel J. If this pin is, as you say, to be about 2½ in. from the centre, you will get a saw stroke of 5 in. How you are to manage this with a fret saw of the usual length is beyond me, even supposing that the fly-wheel is heavy enough, and your strength sufficient to drive it. About 1 in. from the centre will probably be nearer the mark. The length of the rod K is not of much consequence, but be careful not to have it so long as to have the board D in the way of your knees when working the machine. It ought to do as well by carrying it downwards as upwards. The bar F, I am afraid, would not be a sufficient support for the arms of the saw when you are cutting stuff. In turning the wood to the saw there would be an inevitable tendency to twist the back of the frame, which, I fancy, would be against accurate work. You could, however, easily carry out from the back of the table a board on which guides could be fixed for the back of the saw-frame to work in. They would obviate any tendency of the frame to swing round, and diminish the risk of the rod F jamming. This could be prevented by making F round instead

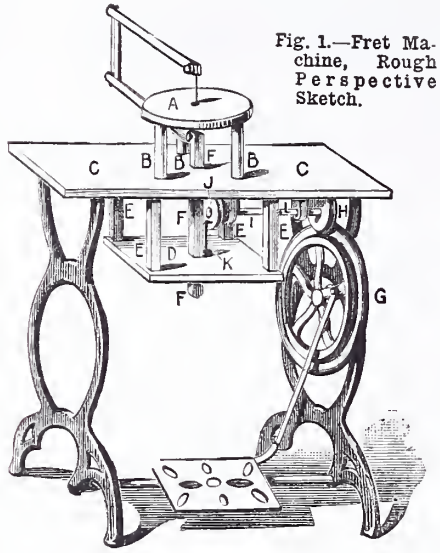


Fig. 1.—Fret Machine, Rough Perspective Sketch.

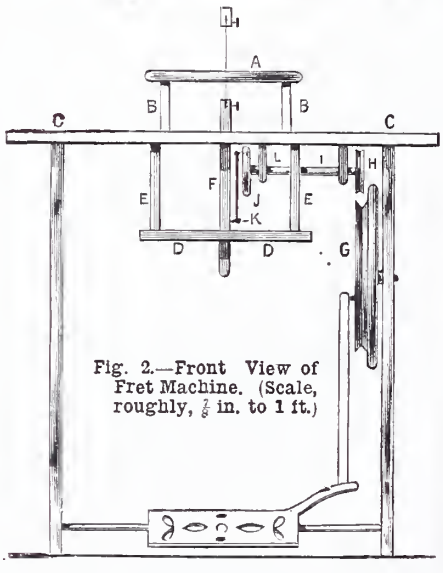

Fig. 2.—Front View of Fret Machine. (Scale, roughly, ⅛ in. to 1 ft.)

of square in section. I do not, of course, know whether you intend making most of the parts of wood—*i.e.*, all that can be—or whether you intend them to be of metal. I, however, imagine the former from your sketches, and if so, the cost of the machine may be less than that at which you could buy one, otherwise it would probably be more economical to get one ready made. The tilting-table may be dispensed with, as it is of comparatively little use, even for inlaying purposes. For ordinary fretwork it is not required. In any case the table should only be made to tilt sideways. Write to the Britannia Company, Colchester, for one of the supports they use for their tilting-table. It will cost you a mere trifle, and you will probably have no difficulty in understanding how it is to be fixed, and in doing what is necessary. We are always pleased to assist our readers, so you need not look on your inquiries as an offence. I wish all inquirers in "Shop" would be as lucid in stating what they want to know, and, whenever they can, would follow your example of sending a rough drawing or two. Inquirers can then be helped more satisfactorily to themselves and with infinitely greater pleasure to the members of the staff to whom the questions may be submitted, than is sometimes the case. I wish you success in your efforts to make the machine, and shall be glad to hear how you succeed.—D. D.

**Dry Battery.**—D. O. W. (*Ipswich*).—I have not had any experience with the dry battery described on page 639 of *Cassell's Magazine* for 1885, so cannot say what the relative proportions of the ingredients may be, nor how it will compare with the Leclanché cell, nor can I say anything about the solution of zinc chloride and ammonium chloride employed in moistening the mixture of manganese peroxide, ferric oxide, and plaster of Paris. The cell appears to be much like the Gassner patent dry battery, and is most likely covered by Dr. Gassner's patent. The lasting qualities of the Gassner have been recently tested by me, and I can highly recommend it. I put a small cell, 6¼ in. by 3½ in. by 1⅞ in., on a 2 in. bell and kept on ringing day by day at the rate of nine hours a day until I got 118 hours' work out of the cell. The power of the Gassner is restored by charging it with an electric current as we charge an accumulator. The battery is sold by Messrs. T. Gent & Co., Faraday Works, Leicester, and wholesale by Mr. P. C. Brewster, 12, Addle Street, London, E.C.—G. E. B.

**Electric Alarm for Clock.**—F. T. (*Silvertown*).—The article on "Electric Time Alarums" appeared in No. 32, published on October 26th, 1889. All back numbers of WORK may be obtained by ordering them of your newsagent or bookseller.—G. E. B.

**Dynamo for Lighting Lamp.**—R. W. D. (*Poplar*).—A small dynamo for lighting one 16 c.-p. lamp, and with power to spare up to 20 c-p. if required, should be of the following dimensions:—Cores of F.Ms., Siemens pattern, 5 in. by 4 in. by ⅝ in. Laminated armature, H pattern, 4 in. by 1¾ in. F.Ms. wound with 4½ lbs. No. 22 double cotton-covered copper wire, connected in shunt with the armature coil. Armature wound with ten ounces No. 20 double cotton-covered copper wire. The armature should be driven at a speed of 2,500 revolutions per minute. To light up a 16 c.-p. lamp this machine will absorb $\frac{1}{10}$ horse power, and to light up a 20 c.-p. lamp will take ⅛ horse-power. I do not expect you will get enough power out of your small model engine to drive the machine, but you can try it when you get the machine.—G. E. B.

**Battery for Lighting Model Church.**—VEGA (*Weston-super-Mare*).—You will require quite 4 pint bichromate cells in series to light up a 2½ c.-p. 8 volt lamp. I do not see how you can improve upon the battery used by you last summer for the same purpose. If you could make up some papier-mâché cells of flat-square form, and make them sound and acid-proof, you might lessen the weight of the battery and the space occupied by it. Directions for working in papier-mâché were given in the early part of Vol. I. of WORK. The cells may be made acid-proof by soaking them, when quite dry, in melted paraffin wax for at least half an hour, then set aside to cool and harden.—G. E. B.

**Safe Carrying Capacity of Wires for Electric Lighting.**—F. E. S. (*London, S.W.*).—I am trying to meet the requirements of young men like yourself, who have to do wiring for electric lighting installations. An abundance of information on the subject lies scattered about in books, but I do not know of any one hook in which you could find it all put as you would wish to have it. Your difficulty seems to lie in your inability to reconcile the decimal system of measurement with the common practice as known to yourself. I really think you will have to surmount this by learning the decimal system, as this is more correct than the old plan of describing diameters by quarters, eighths, sixteenths, thirty-seconds, sixty-fourths, and so on. In the decimal system, each whole unit is divided into tenths, and multiples of tenths, the most popular division being 100. By this system a ¼ is represented by ·25, ½ by ·50, and ¾ by ·75; the point before each figure denotes that the figure is the fraction of 100. It looks much better on paper than $\frac{25}{100}$, $\frac{50}{100}$, and so on. When the whole unit (he this one inch, one ohm, one volt, one ampère, or any other single unit of measurement) is divided into 1,000 parts, the ¼ is represented by ·250, the ½ by ·500, and so on, three figures being used to the right of the decimal point, to indicate that the fraction is in 1,000ths. The measurements thus expressed are finer and more exact than those given in 100ths. When the unit is divided into 10,000ths there are four figures after the decimal point, as ·2500 to express ¼. A little thought on your part whilst reading this will convince you of the superiority (in point of exactness) of the decimal system. In common systems of measurement we have nothing to express our ideas should the measurement exceed by a hair's-breadth the figures marked on our rules, but by the decimal system we can express a shade larger than ¼, by either 26, or ·251, or ·2501, and thus place on paper an exact record of the measurement. This exactitude is necessary in all electric work hence "the elaborate system of decimals used" in the tables of which you complain. Nearly all wire tables give the nearest number in the Birmingham wire gauge to the decimal measurements therein stated; but this antiquated gauge is the most inexact of any known, and therefore fails to express exact sizes. I give herewith a table of the safe carrying capacity of copper wires and cables employed in electric lighting, but must ask you to give your mind to a study of the decimal system of measurement, as this will be in the future, even more than at present, the universal system understood and used by all electrical operators. In the

first part of this table I give the sizes of copper wires in the Birmingham wire-gauge and also their equivalents in decimal 1,000ths of an inch. I also give the economical carrying capacity of each wire, and its safe carrying capacity as well. The carrying capacity is also put in the cables as half their safe carrying capacity, this being found the most economical calculation in laying wires. The information given in the latter part of this table has been obtained from Messrs. J. E. Hartley & Co., Birmingham.

CARRYING CAPACITY OF COPPER WIRES.

Should you meet with any other difficulty, I shall be pleased to help you if you will write again.—G. E. B.

**Zither.**—S. S. (*Stockton*).—You cannot string a zither with piano strings, but must procure a set of melody strings (5), and also a set of accompaniment strings (26). These latter are a mixture, some silver, some copper and others gut. The two sets complete may be had for five or six shillings, according to quality. Send to Chilvers & Co., St. Stephen's, Norwich, if you cannot procure them in your own town. Tutors cost from half-a-crown upwards.—R. T.

**Camera.**—A CONSTANT READER.—If you have a camera for sale you cannot do better than advertise it in WORK.

**Chemical Apparatus.**—PROBYN.—This subject has not yet been treated in WORK in the way you indicate.

**Patent Envelope.**—TEBB STREET.—You cannot do better than consult a wholesale stationer concerning your invention.

**Diamond Chips.**—W. J. C. P. (*No Address*).—I am no authority on drilling china, etc., and I do not quite understand what W. J. C. P. means by "*black* diamond chips." I assume, however, that he means "bort chips," which we use for turning emery wheels, hard steel, and similar work. Bort is a mineral almost, if not quite, as hard as diamond, and is much cheaper. I do not know what firm would be most convenient for W. J. C. P., but Woods & Toussaint, 54, Spencer Street, Clerkenwell, London, are dealers in all kinds of diamond tools, etc., and would, I think, be able to supply him with everything he requires.—DAMON.

**Camera.**—DERF.—In your case, a half-plate Lancaster camera would be a suitable instrument until you became thoroughly conversant with the process. The principal points to look to are: firstly, that the camera is thoroughly sound; secondly, that the focussing sereen and sensitive plate accurately register; thirdly, that the whole is firm and rigid when set up. As a rule these conditions exist in most cameras, or if, by aceident, they do not, a little alteration will put them right. The less intricate the make of the camera, the better it is for beginners. Movements that are especially uscful in a camera are the swingback, and means for raising and lowering the lens. There are scores of cameras in the market that are all that can be desired as working instruments, from 50s. upwards. A good reetilinear lens, suitable for the size of camera, may be obtained from any dealer. To make satisfactory pietures a good lens is *imperative*. If you get a price list from any photographic dealer—Fallowfield's, for example—you will be able to estimate the eost of the outlay to a trifle. The best, or one of the best elementary books is "Burton's Modern Photography." Abney's works on the subject are, for those who know the elementary part, the best published.—D.

**Hints on Boot Finishing.**—S. T. (*No Address*).—I suppose I am to understand by the first part of your letter that you have made a pair of boots and have got all the stuff on, and that you want to know how to finish with a bevel edge, or, anyway, a light edge. Well, this being the case, you eannot make them much lighter than what they are, as the leather should have been fitted to suit your requirements before they were stitched. But, anyway, to finish them off to make them appear as light as possible, trim them round the edge with the knife, then pare, rasp, buff, and sand-paper, as explained in my first paper on "Boot and Shoe Repairing," in No. 112, Vol. III. of WORK. Then, if you have not a welt knife, hold the ordinary knife (with the point flat on the welt) between the thumb and finger, letting the finger form a guard, on the edge of the sole, and trim off the rough edge that the preparing of the edge has thrown on to the welt side, taking off as much as you can without cutting off the heads of the stitches, and then trim as much as you can off the bottom (or sole side). This should be done even all round, so that the edge may be the same substance all round. The welt side can be rubbed down with the bone, and the bottom filed, to make it smooth, being careful not to lift up the channel again. You now paste and ink them in the usual way. With regard to ironing, you must, if you want a good result in either sewn or stitched work, only use the fore-part iron on the sole side. The welt iron I spoke of in my last answer to you is, as stated there, only used for the welt side (from joint to joint), and it is called a jigger-iron. I have given a description of it in the article which appeared on "Boot and Shoe Repairing" (see page 516). It is this iron (or the jigger side of a double iron) that gives the bevel appearance that you saw in the strong-stitched boots you spoke of. I think if you peruse the answer to H. G., in

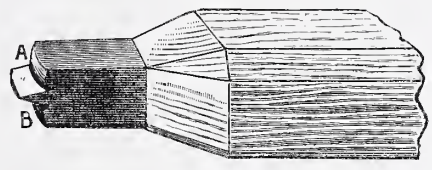

Fig. 1.

Fig. 2.

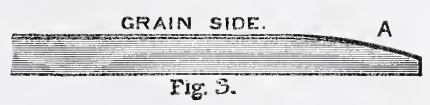

Fig. 3.

**Fig. 1.—Jigger-iron. Fig. 2.—Skiving Leather for Bevel Work. Fig. 3.—Appearance when Stitched, etc.**

No. 97, Vol. II. of WORK, in "Shop," you will find the answer suited to your question. The piece is, as there shown, taken off the grain side. You also ask, should "it be taken off down to about $\frac{1}{16}$ in. at first, and then on the grain side, or flesh side, before sewing into nil, as you do not understand my answer?" You asked in the seventh question of your last (p. 252, No. 120, Vol. III.), if the welt should be thinned down before sewing in? If you refer to the above, you will see I say, "Yes"; but not to $\frac{1}{16}$ in., for you should always buy welts as near the substance of what they are going to be sewn in as you can, for to take a stout welt down to $\frac{1}{16}$ in. would weaken it a deal too much. The welt should have just the thinnest possible layer taken off the grain side, and then taken to the required substance from the flesh side; but this should not need to be much. For bevel, or any light work, always buy light and tight welts. In fitting the sole for bevel work (that is, prior to putting it on the boots), take a piece off all round from the flesh side, to the substance you will require to fit your bevel-iron, allowing for the welt, as shown at A, Fig. 2, or even thinner; and after it is skived off even all round, and put on the boot, it can be hammered at the edge to make it lay flat to the welt, and then when stitched it will look as though it had been taken off the grain side as shown at A, Fig. 3. A bevel-iron is similar to a double-iron, only it has a longer and not quite such a straight guard for the sole side. Your next question, I am sorry to say, I do not quite understand: "How to finish the edge of a pair single sole, pegged waist, thinned down for any iron, and feathered on the welt part." To finish a single sole you need a pump-iron. Fig. 1 is the shape generally used; it is a double pump-iron, A and B being two different substances. This is used, of course, for sewn work. But now I do not know which you mean—the sole or pegged waist thinned down and feathered on the welt part. Pumps have no welts or waist either if they are pegged, and the term feathered is only applied to the inner sole. I am sorry, but an answer would only be at random. If you will now refer to page 845, No. 104, Vol. II. of WORK, you will see that in the answer to POOR SNOB it is stated that the quarter pattern should be cut large enough for the vamp and golosh quarters to overlap to allow for skiving and seam. So you see in cutting the leather you can cut true to the pattern. Some do fold the vamp to cut it equal both sides; but I advise (as the pattern is cut in this way, and is therefore equal) cutting as above, and saving the time of what is called "trenching." You put the pattern on the leather, and a lead weight on the pattern, and you will find it the easiest and best way. To spring a boot, hold the toe in one hand and the heel in the other, putting the waist against the knee, and pulling both toe and heel equally towards you, as you would in breaking a stick, only it must not be done hard. The beating-down is done by holding the upper away from the welt and lightly tapping it down all round on the top of the edge of the inner sole. Its use, as you ask it, is to repair the damage you do in pulling out the last, and to make the feather even and lay flat on the welt. But if ever you have done it, or seen it done, did you not see that it was an improvement to the general appearance of the boot? That is why it is done.—W. G.

**Field Glass.**—H. G. H. (*Saxmundham*) says he has "purchased a pair of field glasses which are very weak," and asks, "can he buy stronger glasses and fix them himself, and where, and at what cost, etc.?" This is one of those letters which, to say the least, is not easy, if not impossible, to answer. Is the glass weak in magnifying or defining power? Two very different things. Glasses of any strength or quality can be procured of any optician; but how can one tell if H. G. H. ean fix them himself? Are the lenses screwed in eells or fixed in bezels? If the former, the work is easy; if the latter, a lathe and some skill are required to do the job. As to where the lenses can be bought, I have found Lancaster, of Birmingham, exceedingly obliging, and he can supply what you need. As to cost, they ean be purchased from 6d. upwards, according to size and quality. If H. G. H.'s object glasses are all right, but the instrument does not magnify high enough, this can be remedied by employing an eye-piece of shorter focus. If the object glasses are common chromatic lenses, then nothing can be done to improve the definition but employing better lenses, which, at least, would cost about 5s. each. If the instrument is one for which a fair price was paid, then really the best plan would be to send it to a practical optieian, such as the one I have named, and ask him to rectify it. If H. G. H. wishes to do the work himself, then Mr. Lancaster will supply the material needed. But from the letter, as a whole, I judge that H. G. H. has no knowledge of the kind of work requiring to be done; if so, he might ruin what after all is, but for some slight defect, a fairly good instrument. I think no one can give more definite advice without an examination of the instrument.—O. B.

**Wardrobe.**—AMATEUR.—An article on making a wardrobe appeared in No. 116 of WORK.

**Cost of Work.**—AMATEUR.—The volumes of WORK bound cost 7s. 6d. each. The twelve parts that are comprised in the volume cost 6s. The fifty-two numbers, of which each volume is composed, cost 4s. 4d.

**Gesso Work.**—H. G. will find it the best plan to purchase the gesso ready prepared from the Society of Artists, Bond Street, W. It saves trouble, and for small pieces of work (such as a frame) the difference in cost is not worth thinking about. It is difficult to give quantities, but the ingredients must be warmed over the fire to form a thickish batter. The gesso is laid on with a brush, and often modelled with the end of the handle. It would be a help to H. G. if he were to see the specimens at the Society of Artists; but, after all, these only show a few of the ways in which gesso can be employed for deeoration. I have never tried using it as H. G. suggests; but it probably might answer his purpose, though it certainly would not be such an artistic deeoration as if a brush were used. Full direetions were given in WORK, September 7, 1889, December 28, 1889, and February 15, 1890.—C.

**Galilean Telescope.**—F. W. L. (*Southborough*).—To make the telescope you describe, you will need an object glass 2½ in. in diameter and 25 in. in focal length (which will cost you from 4s. 6d. to 25s., aecording to whether it is a common single lens, or a properly corrected achromatic lens), and a plano-concave eye-lens of ½ in. focal length (which will cost about 2s.). These lenses can be obtained through any working optician. The foregoing priees are taken from the price list of Messrs. James Lancaster & Son, of Birmingham. But after you have bought your lenses and followed out your plan, the telescope is not likely to be of the slightest practical use to you. The field of view would be altogether too small. A Galilean telescope serves excellently as a field or opera glass, where small magnifying powers only are needed; but it is seldom used nowadays for any other purpose. You had better let the Editor know exactly what you want the teleseope for, and then I will tell you the best way to set to work. To follow out your present plan will be to waste money and to court a serious disappointment.—E. A. F.

**Graining and Decorating.**—EXILE.—To properly advise a "young grainer and decorator what books to study" would be easier done if you had given some particulars of the extent of your present knowledge and skill. As a general instruction, I would advise you to read and study anything and everything bearing upon form and colour, and particularly all that connects the same

with the applied and industrial arts. To particulariso books and prices, I can easily give you a few for you to make regular companions of. Subscribe to the *Journal of Decorative Art*, and write its editor—who is himself a very experienced and rising specialist in all branches of decorative art—for a list of publications. The price of this is 7d. monthly, from 15, St. Ann Street, Manchester, and all booksellers. Send also to Crosby Lockwood & Co., Stationers' Hall Court, E.C., for their list, and of these, Field's "Grammar of Colouring" (3s. 6d.) is one of the most useful. Then save your money, and buy the late Owen Jones' "Grammar of Ornament" for cash, about £1 (published at 5 guineas, and the original edition at 12 guineas). Then on "from strength to strength" to Ogden Rood's "Chromatic Equivalents" (5s.), of Kegan Paul, Trench & Co.; and also Prof. Church's revised "Colour" (3s. 6d.), of Cassell & Co. Then write me again; but in the meantime you may gather a few crumbs from WORK.—DECORATOR.

**Sun-dial.**—A. R. (*Birmingham*) asks "how to find the angle of the gnomon for the latitude of this city (Birmingham) for a horizontal sun-dial." It must be understood that the angle for a gnomon in a given place is the same as the latitude of the place. If you refer to an index of latitude and longitude, you will see that Birmingham is 52½° north, which must be that of the gnomon; in other

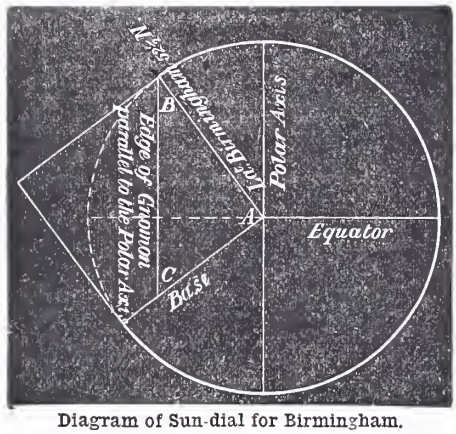

Diagram of Sun-dial for Birmingham.

words, the edge of the gnomon casting the hour shadows must be parallel with the polar axis. There are various ways of finding this, all simple; this is as good as any: draw a circle, or, better still, use a map of the world; draw a line from the centre to 52½°. Place a square piece of paper or metal, with the point, A, at the centre, with the edge, A B, along the line from the centre to 52½°. Now draw a line, B C, parallel with the polar axis, which gives us the angle required. A C is the base, and B C is the edge for the hour shadow. A B and A C must be perfect right angles. A. R. asks for a diagram, which I subjoin, if needed.—O. B.

**Tarred Wall.**—E. J. (*Barnsley*).—Were it woodwork, it might be worth your while to remove the objectionable stuff by dry scraping, or "perishing" it off by heat or solvent: but for a brick wall it is the last thing I would recommend you to do. Your best plan, I think, is to coat it with limewash, and if it is required to stand much rain and weather, stir some hot Russian tallow into it. Several coatings of this would surely make it light and clean enough looking for you, and at one-tenth the cost of cleaning and oil-painting. Give your orders to a local bookseller, or if he doesn't show proper knowledge and enterprise in procuring books, order them at a station bookstall. Smith's representatives will usually get anything with but little trouble.—F. P.

**Cement.**—W. V. C. (*Dublin*).—The ordinary plaster of Paris is the usual article employed in fastening the glass and metal parts of lamps together, and I do not think it could be substituted by anything cheaper or better, as well as for the purpose you mention. Plaster may be mixed with patent knotting with advantage for some purposes, but, if anything, it is more objectionable to handle thus. Plumbers' putty (made with white lead stiffened up with red lead) is also used for fastening plugs, etc., to glazed earthenware, as aqueous fluids would not affect it like plaster.—F. P.

**Washable Wall Papers.**—A STAINER (*Glasgow*).—The information you desire I am unable to give you, and I scarcely think it is likely to find its way into print, unless a reader of WORK employed in making the "sanitary" papers is able and willing to give the process. The well-known firm of paper-stainers, Messrs. Heywood & Higginbotham, were, I believe, the first to make "sanitaries," and I believe it was then, to some extent, a "patent" process. Most of the chief paper-stainers now make them; Lightbown and Aspinall, especially, do a large business with them. I have heard it remarked that some "hot-press" process is used, but personally have no knowledge. Doubtless there is more in it than a "vehicle," probably expensive machinery. Stather's washable goods (Hull) are different to the ordinary sanitary, being printed in materials of an oil-paint nature.—F. P.

**Protected Invention.**—WORKING MAN.—As you have obtained provisional protection for your invention, whatever it may be, for nine months, you can apply to private firms, who may be likely to take it up without the intervention of a patent agent.

### III.—QUESTIONS SUBMITTED TO CORRESPONDENTS.

**Lathe for Umbrella Sticks.**—E. E. (*Walsall*) asks:—"Will any reader inform me through 'Shop' where I could get the best lathe for cutting the spring-holes in umbrella sticks?"

**Lapidary Work.**—SPES MEA writes:—"Would some reader of WORK tell me how I can best proceed to cut some stones that I have picked up during my rambles on the sea-shore, and where I can best obtain the necessary tools, etc., for this purpose?"

**Colouring Bright Steel Surfaces.**—BARIUM writes:—"Will some reader be good enough to inform me how this can be done without greatly heating the articles? The process must be cheap, as I want to colour about 8,000 articles weekly. I want a bluish self colour, similar to that of a watch spring."

**Waterproof Glue.**—LONDON asks where "waterproof glue can be procured."

**Still.**—LONDON asks for "particulars of a still for distilling wood."

**Glass Blowing.**—SPES MEA writes:—"May I take the liberty of asking some of the many readers of WORK to favour me with information respecting the apparatus necessary for blowing glass on a small scale, and the best place to obtain them?"

**Demon Water Motor.**—SPES MEA writes:—"Would any kind readers of WORK who have actually used the above motors, kindly inform me as to the general capability, strength, durability, efficiency, and reliability of these motors for turning grindstones, circular saws, etc., and whether in construction they are really a reliable motive power for the purposes mentioned. I should add that I more particularly refer to the larger-sized motors, namely, the ½ and 1 horse-power."

*** I reply to this at once by referring SPES MEA to a notice of the so-called "Demon" Water Motor, which appeared in WORK, Vol. III., page 122. This is a sufficient answer, and no replies from correspondents, should there be any, will be inserted.—ED.

### IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Bamboo Work.**—C. R. K. writes, in reply to E. C. W. (see page 416, No. 132), that he "can find everything he requires at Messrs. Heinriehs & Co., Old Street, E.C."

**Wire Crimping.**—THE PHOSPHOR BRONZE COMPANY write:—"We can supply castings in phosphor bronze, but we require a wooden pattern to make same from. Anyone could either supply us with the pattern, or if a wax pattern was sent, we could get a wooden one made and charge simply the cost price of same."

**Boiled or Unboiled Oil.**—H. E. (*Croydon*) writes, in reply to A WEEKLY SUBSCRIBER (see page 459, No. 133):—"It depends entirely upon what colours you intend using for your external painting. If you use a colour of which white lead forms the substratum, it is not usual to use 'boiled' oil. If you are using dark colours they should be mixed with it, as otherwise they lack the body of 'white lead' paints. You will get no paint to look like varnish after two or three years, however you may mix it. If a glossy appearance (permanent) is desired, you must varnish the work, and even this will dull very considerably after two or three years' exposure to the atmosphere."

**Tuck-pointing.**—H. E. (*Croydon*) writes, in reply to SLATER:—"If you wish to tuck-point the front of a red brick house, it is usual to rake out the mortar from the joints, give the bricks a coat of venetian red in turps, and then 'flush up' the joiuts with black mortar (made by mixing vegetable black with the ordinary mortar). The 'tuck-pointing' proper consists of laying fine lines of white mortar neatly and regularly over the centres of the joints. This is done by means of a special trowel and a straight-edge. Stock facings are coated with yellow ochre previous to 'flushing;' but it is not usual to colour *malms*. The term is apparently derived from the German 'tuchen' (to fold or press in), or 'zucken' (to shrink in). I need scarcely say that it is not a novice's job."

### V.—BRIEF ACKNOWLEDGMENTS.

Qnestions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—R. H. (*Bishop Auckland*); EQUATOR; MAOPIE; P. A. (*Newquay*); WATER MOTOR; NIL DESPERANDUM; J. H. (*Bishophill*); E. G. (*Hereford*); R. K. B. (*Woolwich*); BRASSY; E. M. (*Blackheath*); R. R. (*Liverpool*); ENGRAVER; J. A. B. (*Camberwell*); F. H. *** Advertisements should reach the Office fourteen days in advance of the date of issue.

## *SITUATION VACANT.*

**Handy Man.**—Wanted, for constant occupation in a large country house and grounds near London, a trustworthy man. He must be a competent joiner and carpenter and well acquainted with the other building trades. —Apply, by letter, to E. M. JONES, La Belle Sauvage, London, E.C.

## *SALE AND EXCHANGE.*

**Bcit's Patent Enamelled Adhesive Waterproof Advertising Paper Letters and Figures** in all colours and sizes. Best and cheapest. Liberal terms to agents. Sample sheets, gratis. Factory, 17, Arthur Street, London, W.C. [17 R

**Victor** Cycle Co., Grimsby, sell Mail-cart Wheels and Parts. [15 R

**Who's Lunt?**—Why, the Best Man for Joiners' Tools, of warranted quality. Send stamp for our Seventh Edition Reduced Price List.—LUNT, Tool Merchant, 297, Hackney Road, London, E. [13 R

**Walker Bros., Leeds.**—Mail-cart wheels and axles. [5 R

**The Universal Amateur Exchange.**—Electrical, Optical, Mechanical, Chemical, Photographic, etc. Established 1862. Catalogues, 2d.—A. CAPLATZI, Chenies Street, Bedford Square. [8 R

**Price List** of Carpenters' Tools, containing nearly 400 Illustrations, free by post.—OSBORN BROTHERS, Tool Merchants, Portsmouth. [16 R

**The Talmer does the Best.**—Illustrated pamphlet of this perfect Hand Camera 2 stamps.—TALBOT AND EAMER, Blackburn.

**Photographic Apparatus,** list 2 stamps. Dark Slides, best quality, fitted to any camera: ¼ plate, 5s.; ½ plate, 9s. 3d. All sizes made.—TALBOT AND EAMER, Blackburn. [18 R

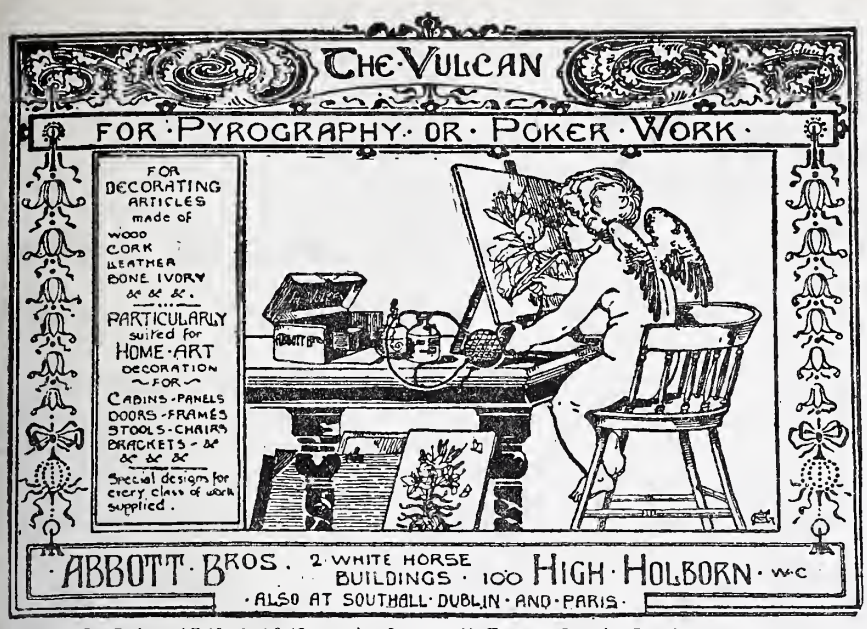
**Fretwork Designs.**—Books of 12, 7d. and 1s. 1d.; 40 smaller designs, 7d.; sample sheet of 6, 2½d. Fretwood from 4d. per foot.—TAYLOR'S Fretworkeries, Blackpool. [19 R

**Picture Moulds.**—15 to 25 per cent. saved. Send for wholesale list, one stamp.—DENT'S, Importers, Tamworth. [3 R

**Catalogue of New Tools, 6d.**—Monthly Register, containing details of upwards of 3,000 (three thousand) new and second-hand Gas and Steam Engines. Boilers and every description of Tools and Plant wanted and for sale; cash or hire purchase.—Call at 100, Houndsditch, London; or send 4d. for Register to BRITANNIA CO., Colchester. [7 R

**Lettering and Sign-Writing made Easy.**—Also full-size diagrams for marking out eight alphabets, only 1s.—F. COULTHARD, Darlington Street, Bath (late Bournemouth). 100 Decorators' Stencils (60 large sheets), 2s. 6d.

**Fret, Carving, and Repoussé Patterns.**—100 of either, full-size, 1s.; 35 Fret Photo Frames, 1s.; 30 Fret Brackets, 1s.; 100 Sign-writer's Stencils, 1s.; 300 Turning Designs, 1s.; 400 small Stencils, 1s.; 500 Shields, Monograms, &c., 1s., postage free.—F. COULTHARD, Darlington Street, Bath (late Bournemouth).



MACHINES, Price 15/6 & 10/6 each, from all Fancy Goods Dealers and Art Depôts.

LEE'S ILLUSTRATED CATALOGUE OF SELECTED

## AMERICAN TOOLS and MACHINERY.

Screw Cutting and other Lathes, Chucks, Slide-rests, Lathe Dogs, Polishing Lathes, Drilling Machines, Drills, Parallel and Instantaneous Grip Vices, Screw Stocks, Taps and Dies, Saws, Wrenches, &c., &c., specially selected from the best American Manufacturers, therefore of the very highest quality, and at low prices. *Send for Illustrated Catalogue, 150 Illustrations, price 6d., post free.*

MODEL STEAM ENGINES, and Complete Sets of Castings of same, of every description, from the smallest to powerful Engines.

**LEE'S ILLUSTRATED CATALOGUE.**

New and Revised, Prices greatly Reduced. To Amateurs the most useful book extant, and largest and best Catalogue in the Trade. 64 pages, 110 Illustrations, price 6d., post free. Please state whether American Tool or Model Steam Engine Catalogue is required when ordering. ONLY ADDRESS— *76, 77, and 78a, HIGH HOLBORN, LONDON, W.C.*

Gateway entrance directly opposite the Inns of Court Hotel. Awarded Prize Medal International Inventions Exhibition, 1885. Please name this Paper when writing.

## FRETWORK FOR AMATEURS

OF BOTH SEXES AND ALL AGES

The most Fascinating and Profitable of all Home Pastimes

250,000 Fretwork Designs, 100,000 ft. Solid & 3-Ply Fretwood Veneers, etc., 1,000 gross Fretsaws, etc., always in Stock.

**To Beginners—A Complete Outfit, 2s. 6d., post free.**

Comprising 12 in. Steel Frame, 24 Saw Blades, Awl, File, 3 Designs, with sufficient planed Fretwood, and full Instructions. 6 ft. assorted planed Fretwood, 2s. 6d.; 12 ft. ditto, 4s. 3d., post free. Book containing 12 sheets full-size Designs, 1s. Fretsaws 1s. 4d. per gross.

New Catalogues of Machines, Designs, Wood, Tools, etc., with 60 pages and 600 Illustrations, and full instructions for Fret-cutting, Polishing, and Varnishing, price 4d., post free. A Specimen 6d. Fretwork Design SENT GRATIS with each Catalogue; also a List of Designs, Outfits, Tool Chests, etc., at Greatly Reduced Prices to clear. N.B.—All orders MUST be accompanied by remittance. Apply—**J. H. SKINNER & CO.**, Manufacturers of Fretwork Materials, W Department, **East Dereham, Norfolk.**

# A WONDERFUL MEDICINE.

# BEECHAM'S PILLS

Are universally admitted to be worth a Guinea a Box for Bilious and Nervous Disorders, such as Wind and Pain in the Stomach, Sick Headache, Giddiness, Fulness and Swelling after Meals, Dizziness and Drowsiness, Cold Chills, Flushings of Heat, Loss of Appetite, Shortness of Breath, Costiveness, Scurvy and Blotches on the Skin, Disturbed Sleep, and all Nervous and Trembling Sensations, &c. &c. The first dose will give relief in twenty minutes. This is no fiction, for they have done it in countless cases. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

**Worth a Guinea a Box.**

FOR FEMALES THESE PILLS ARE

"A priceless boon, a treasure more than wealth; the banisher of pain, the key to health."

These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the nervous and debilitated is,

***BEECHAM'S PILLS have the Largest Sale of any Patent Medicine in the World.***

Prepared only by the Proprietor, T. BEECHAM, St. Helen's, Lancashire, in Boxes 9½d., 1s. 1½d., and 2s. 9d. each. Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*

Marvellous Purifier — Matchless Preserver — Pure Antiseptic.

# "CALIFORNIAN"

"The Household Treasure" Borax,

**Specially Prepared for Personal, Domestic, and Sanitary Uses.**

***Packets, 6d., 3d., and 1d. each.***

Sold by all Grocers and at Stores.

**PATENT BORAX CO.,** *Sole Makers. Works: BIRMINGHAM.*

## FRETWORK PATTERNS.

FRETWORKERS who appreciate First-class Designs should write for our Catalogue of nearly 400 Patterns, admitted to be the best in the Trade. Catalogue sent post free on receipt of 4d., stamps. List of Tools and Materials is also enclosed.

BOOTH BROTHERS,
TOOL MAKERS,
DUBLIN.

## C. BRANDAUER & Co's CIRCULAR POINTED PENS

NEITHER SCRATCH NOR SPURT.
SAMPLE BOX 6D. OR FOR 7 STAMPS
BIRMINGHAM. [33

London Warehouse: 124, NEWGATE ST.

## SPEAR & JACKSON'S HIGH CLASS *HAND-SAWS.*

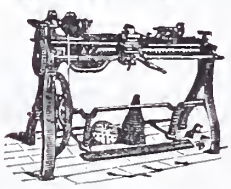
OF ALL IRON-MONGERS.

AWARDED 3 GOLD MEDALS.

Finest Cast Steel, Patent Machine Ground and Tempered.
*Manufactory—Etna Works, Sheffield. London Warehouse—22, Queen St., E.C.*

## HENRY MILNES,

*MANUFACTURER OF*



HIGH-CLASS LATHES
FOR
SCREW-CUTTING & ORNAMENTAL TURNING,
TREADLE MILLING MACHINES, HAND PLANING MACHINES, &c.

*Ingleby Works, Brown Royd, Bradford.*

ACCURACY AND LIGHT RUNNING GUARANTEED. **ESTABLISHED 1858.**

*The* ONLY *Permanent and Washable Enamel* GOLD *in the Market.*

REQUIRES NO VARNISHING.

ALSO ELEVEN OTHER BEAUTIFUL SHADES OF BRONZES.

READY FOR USE.

Will keep its brilliancy for years.

## ARDENBRITE LIQUID GOLD

To be had everywhere in 6d., 1s., 1s. 6d., and 2s. 6d. Jars.

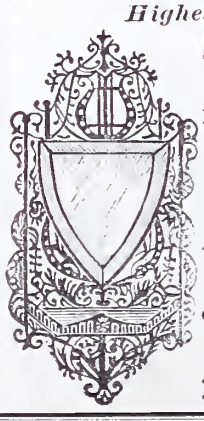
*Sample 1s. Jar, post free with Shade Card, of*

T. PAVITT & SONS,
70, SOUTHAMPTON ROW, W.C.

*N.B.—Beware of explosive mixtures sold as Liquid Gold, made of highly inflammable Benzoline.*

## FRETWORK AND CARVING.

*Highest Award—GOLD MEDAL.*



MACHINES, DESIGNS, TOOLS, WOOD, MIRRORS, HINGES, AND VARNISH, &c.

Fretwork Outfits, 1s. 4d., 2s. 6d., 3s. 6d., and 5s. 6d. each.

*Sets of Twelve Best Carving Tools, with Boxwood Handles, 10s. free.*

All Materials and Tools supplied for Fretwork, Carving, Picture Framing, Brass, Leather, and Burnt Wood Work.

Our Catalogue, acknowledged the most complete, with 1,000 Illustrations, and all Instructions, free for six stamps.

## DESIGNS FOR PANELS, ETC., IN FRETWORK.

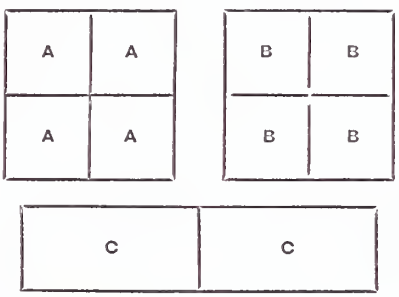
BY J. EADIE REID.

Of all productive amusements, illumined by the cheery glow of a winter's night fire, there is none, perhaps, more "fascinating and profitable" than fretwork. The numerous articles, both useful and beautiful, adorning the walls of our pet rooms and filling their corners are rich in memories of such evenings.

In my sketches in the preceding page, I have striven to supply range for such employment, and trust that while affording scope for technical skill, the sketches will illustrate my theory as to the fitness of the design to the material. This is a point which cannot be insisted upon too emphatically.

Without in any way wishing to depreciate designs published for fretwork—and many are of exceeding beauty—I do think that a great deal of energy is wasted over work more fit for shadow pantomimes rather than decoration.

The drawings given are capable of being repeated, as shown in the following diagrams. The border design might be utilised as a frame or back of pipe-rack, etc.



Fretwork can also be applied to metal work. I have seen a very charming stove cover executed in this way, the design being modelled in repoussé. Finger-plates might be carried out in this method, and the inventive minds of our readers will suggest other outlets.

## PRACTICAL PAPERS FOR SMITHS.

BY J. H.

### Hardening and Tempering.

The Term Steel—Carbon in Steel—Mr. Seebohm's Classification—Secondary Agents — Definitions — Hardening — Tempering—Annealing — Hammer Hardening — Chisel Tempering—Tempering on a Bar—Grades of Temper—Colours—Effect of Steam—Warping and Cracking — Correcting Crooked Work—Thick Edges—Hardening Agents.

*The Term Steel.*—No confusion need arise in our minds as to the proper application of the term steel. For our purpose we shall only consider the two broad divisions into mild steel that will not harden and temper, and high carbon or crucible steel that will harden and temper. Steel castings, with which we are not concerned, will not harden at all.

*Carbon in Steel.*—The purer the mild steels—that is, the nearer they approach to the condition of malleable iron—the more ductile and the more weldable they are. On the other hand, their capacity for hardening and tempering diminishes. Carbon is the principal hardening element. Yet in no case does the proportion in which it is met with equal that in cast iron. In steel it seldom or never amounts to more than 1·5 per cent. It is as low as ·1 per cent. in the mildest plates.

*Mr. Seebohm's Classification.*—Mr. Henry Seebohm, a Sheffield manufacturer of eminence, read a paper a few years ago at the Chester meeting of the Iron and Steel Institute. In that he very happily likened hardened steel to glass, annealed steel to lead, and tempered steel to whalebone. He gave a list in that paper of the most useful kinds of steel, regarded from the standpoint of temper. I need not apologise if I make use of that list in this article.

Razor temper (1½ per cent. carbon).—This steel is so easily burnt by being over-heated that it can only be placed in the hands of a very skilful workman. When properly heated, it will do twice the work of ordinary tool steel for turning chilled rolls, etc.

Saw-file temper (1⅜ per cent. carbon).—This steel requires careful treatment, and although it will stand more fire than razor steel, should not be heated above a cherry red.

Tool temper (1¼ per cent. carbon).—The most useful temper for turning tools, drills, and planing-machine tools, in the hands of ordinary workmen. It is possible to weld cast steel of this temper, but only with the greatest care and skill.

Spindle temper (1⅛ per cent. carbon).—A very useful temper for circular cutters, very large turning tools, taps, screwing dies, etc. This temper requires considerable care in welding.

Chisel temper (1 per cent. carbon).—An extremely useful temper, combining as it does great toughness in the unhardened state, with the capacity of hardening at a low heat. It is consequently well adapted for tools when the unhardened part is required to stand the blow of a hammer without snapping, but where a hard cutting edge is required, such as cold chisels, hot setts, etc.

Sett temper (⅞ per cent. carbon).—This temper is adapted for tools where the chief punishment is on the unhardened part, such as cold setts, which have to stand the blows of a very heavy hammer.

Die temper (¾ per cent. carbon).—The most suitable temper for tools where the surface only is required to be hard, and where the capacity to withstand great pressure is of importance, such as stamping or pressing dies, boiler cups, etc. Both the two last tempers may be easily welded by a mechanic accustomed to weld cast steel.

*Secondary Agents.*—In addition to carbon, but in a lesser degree, manganese, phosphorus, and silicon are hardening constituents of steel. Within certain limits, the more these hardening constituents are present in steel, and the lower the temperature of the cooling liquid employed, and the greater its power of absorbing heat, the more intense will be the hardness induced in the steel. Mushet steel, used for turning tools, is produced by the addition of wolfram or tungsten, in the form of a metallic alloy, to steel. The resulting alloy is so hard that it does not require to be hardened by the tool maker.

*Definitions.*—My technical friends will pardon me if I explain, in the interests of the "general reader," the meaning of three common terms that will be frequently used in this and in the next article. They are "hardening," "tempering," and "annealing."

*Hardening.*—The process of hardening, as commonly understood by smiths, means the heating of a piece of steel to a high temperature—a full red, or a cherry red—and plunging it at once and completely into a cooling liquid, either water or oil, pure or medicated. This causes the steel to become hardened—as hard as it is possible for it to be made.

*Tempering.*—Tempering means that the steel is re-heated to a temperature very considerably below its previous heat, and when at a certain precise temperature, indicated by a definite shade of colour, it is plunged into a cooling liquid, or in some few cases is allowed to cool gradually in air. This grade of tempering is different in the case of almost every tool or piece of mechanism.

*Annealing.*—If the steel is heated to a high temperature, usually above that required for tempering, but below that for hardening, and allowed to cool slowly in air or in ashes, the steel is then said to be annealed. Steel may be annealed by getting it red hot, and allowing it to cool between hot cinders. Or it may be left in a low fire until the fire has gone out and the cinders have become cold. Or it may be enclosed in a box with charcoal powder, raised to a red heat, and allowed to become cold.

In the first case, therefore, the steel is brought into a condition intensely hard, like glass; in the second, into one softer and less brittle than the first—the whalebone condition—but yet as a rule very hard; in the third, it is in its softest possible condition, akin to that of lead.

*Hammer Hardening.*—Hardening by means of hammer blows is of occasional service when it is desired to increase the elasticity and hardness of a plate or lamina of steel. Its effect is similar to that of cold rolling and of wire drawing, and is removed by annealing. If hammer hardening is prolonged too far, the metal becomes fractured; hence, annealing must be resorted to before this stage is reached. The range of temper obtainable in hammer hardening is not so great as in the ordinary method of heating and quenching in water, and it has a more limited value, being confined chiefly to laminated springs.

*Chisel Tempering.*—The typical method by which much work in the tool line is tempered is this: Say the article is a cold chisel. The scale is removed from the surface, as it must be from all work that has to be hardened. It is then first heated to a cherry red in a clear fire—just the cutting end only—to the length of about a couple of inches, and is then quenched in water. It is taken out and rapidly brightened with a bit of grindstone or emery, in order that the rapidly changing hues may be observed the better. Though the cutting end has been cooled in the water, it is only for an instant, for the heat of the shank at once begins to be communicated to that end, and raises its temperature, until the instant arrives at which it must be quenched for tempering. The smith then plunges the entire chisel into the water, moving it to and fro until quite cold. The colour for tempering in the case of a cold chisel is a deep straw inclining to purple. But, as I cannot too often reiterate, the colour must vary with different grades of steel.

*Tempering on a Bar.*—Another way suitable for many small tools is to heat a bar of iron to redness in the forge fire, and lay the tools upon the bar until they reach the colour required for quenching. If the bar is made red hot at one end only, the tools can be gradually slid along toward that end, and so slowly heated thoroughly through,

until they reach the precise tint for tempering.

*Grades of Temper.*—But all cutting tools of the same type are not tempered alike. Thus, turners' roughing tools or fitters' chisels will be tempered at different shades of colour, according to the material they are specially intended to operate upon. A tool for working hard cast steel will be made harder than one for working grey cast iron. A tool quenched at a straw colour is harder than one quenched at a blue; so that if tools for hard steel are tempered at a straw, those for soft iron and brass are tempered at a tint between straw and, say, purple.

*Colours.* — The main colours through which steel passes from the lowest to the highest temperature are straw, gold or yellow, chocolate, purple, violet, and blue. These, with their intermediate shades, are the indications of the temperatures for quenching for different tools.

*Effect of Steam.*—During quenching the steel should not be allowed to remain still, but be moved about. There is an important reason why steel should be moved about in the water during hardening. Water in contact with red-hot metal assumes the spheroidal state, and prevents perfect contact between the surface of the metal and the cold water. Moving the steel about, therefore, assists in maintaining a more perfect contact by bringing it into colder strata. This also is the reason why, when hardening large masses, such as the faces of anvils, the practice is to pour a stream of water over them. For the same reason, mercury is a better hardening agent than water. Plunging small articles into cold lead or into tallow, or placing them between cold iron, are for the same reason perfect methods of cooling, there being no formation of steam. Further, sharp angles should be carefully avoided in work that has to be hardened. They invite cracks just as similar sharp angles do in castings.

*Warping and Cracking.*—Hardening steel often causes it to become cracked and warped out of truth, though no sharp angles are presented. The reason is this: On dipping the steel into the cooling medium, the outer covering is rapidly cooled off first, and shrinks upon the interior. The shrinkage puts the outside into tension. Presently the interior cools. But it is prevented from free shrinkage by its union to the set exterior, and is thus itself put into tension, so that two things may happen: either there will be a condition of permanent tension, productive of warping or curvature, or the stresses will find relief in fracture. And this is why hardening is so apt to curve or crack the object. And since the effect of water hardening is more pronounced than that of oil or tallow hardening, it is customary to use oil or tallow in preference to water in all delicate works. Moreover, in order to lessen the liability to curvature, long narrow articles are immersed perpendicularly instead of horizontally or diagonally in the fluid, so that its effect may be evenly distributed over the whole of the surface. Again, steel that is taken out of the water before being thoroughly quenched is apt to crack. And steel is apt to crack at the water level if kept at the same height. It should therefore be moved slightly up and down in the water. When dipping articles of unequal thickness on the edges, the thicker edge, as a rule, should be dipped first, to lessen risk of cracking.

*Correcting Crooked Work.*—Thin work that goes crooked during tempering may often be corrected after hardening, and while at the heat for tempering, with a cross-pane hammer, operating on the concave face.

*Thick Edges.*—When tempering cutting tools, the edges should invariably be left thick, to be reduced afterwards by grinding. If tempered thin, the edges will be liable to be burned, and if not burned, the temper of the edge will not be the same as that of the thicker portion. But if tempered thick and then ground down, the temper will be uniform throughout.

*Hardening Agents.*—Almost every smith has his favourite hardening agents. The principal are cold water, medicated in various ways, chiefly with salt, and also lukewarm water, and oil. Mercury has been used and recommended, and since it is a good conductor, and no film of steam can form between it and the work, it should be very efficient. But of course its expense precludes its use for average work, and we may dismiss it at once. For most purposes of the ordinary smith, pure cold water only is used. For light and delicate work, however, oil is preferable. In the next article I shall write at length on the principal fluids and mixtures made use of.

## SOME LESSONS IN WINDOW MAKING.

BY G. LE BRUN.

### Roof-lights and their Construction.

When the worker has mastered the "setting-out," mitring, and putting together of an ordinary dead-light, or fixed sash, he will be the more competent to try his hand at the making of roof-lights, which, although to many they appear more difficult, are in reality easier to make than a sash having cross-bars. For the sake of an example, we will suppose that we have to make the roof-lights for a greenhouse similar to that described in the paper on "The Tenant's Greenhouse," in WORK, Vol. I., page 177. We will thus have a definite object to take the sizes from, and the lesson may prove doubly useful to those who are at work on the house there described.

Turning back, then, to Vol. I., page 177, we find that to cover in the roof four sashes are required. In an erection intended for a permanency, two roof-lights extending the whole length of the building would be the proper mode of construction; but, as in the case before us, portability is an object of importance, the roof-lights are made in four sections (two for each side), so as to allow of ease in handling when taking down or erecting. The number, however, is immaterial—four will do as well as two for our lesson—as the difference after all is only in the respective sizes of the sashes, and does not in the least affect their mode of construction.

We require, then, four roof-lights, each 5 ft. 10 in. high and 6 ft. 2 in. wide, and for these we shall want material as follows:—Eight stiles, 6 ft. 2 in. by $3\frac{1}{2}$ in. by 2 in.; four sole rails, 6 ft. 3 in. by 5 in. by $1\frac{3}{8}$ in.; four top rails, 6 ft. 3 in. by 3 in. by 2 in.; sixteen sash-bars, 5 ft. 11 in. by 2 in. by $1\frac{1}{2}$ in. These are the sizes in the rough, allowance being made in the lengths for stumps on the stiles and tenons. Prepare the wood carefully by planing up straight and square, and pay attention to the running of the grain in the direction in which the planes run when rebating and moulding, as explained in the previous lesson on dead-lights.

Take the stiles first, and lay them on the bench, in pairs, alongside each other, the marked or inside edge being uppermost. Lay a sash cramp across them, and tighten it up sufficiently to prevent the stiles slipping away from each other; put a bit of wood between each jaw of the cramp to prevent marking the material, and keep it up far enough above the edges to allow of your rule passing beneath when measuring, taking care also that the ends of the stiles are flush. Draw a line across the stiles 2 in. from the left-hand end, measure off 5 ft. 10 in., and draw another line across. The distance between these lines is the height of your sashes (A, A, Fig. 1). Now at the left-hand end measure off from your first line 5 in., and at the right-hand end 3 in. These are the widths respectively of the sole and top rails (B, B, Fig. 1). Let the top rail have a rebate of $1\frac{1}{4}$ in., and the sole rail 2 in. (C, C, Fig. 1). The distance between the lines, C, B, is the length of the mortises, and you will notice that at the sole end of the stiles they are continued to the full width of the rail, the part extending from A to C, however, being only $\frac{5}{8}$ in. deep. This is to allow for the insertion of the piece of tenon left on to steady the rail, and also to prevent leakage. This piece, with mode of cutting the tenon of the rails, is shown in Fig. 4.

Turn the stiles upside down, and draw across the lines, C, B, on the back edges, leaving an allowance of $\frac{1}{2}$ in. at each side of the mortises to allow of the insertion of the wedges. In turning the stiles over, get the assistance of another person, each holding the ends tightly, so that they may not slip away from each other endways; if you attempt to turn them yourself by lifting them in the middle, the probability is that you will drop them, or shift all your marks away from each other. Set the mortise gauge for a $\frac{5}{8}$ in. chisel, and run it, as in the previously described sash, $1\frac{1}{8}$ in. from the face. Take the top rails, and lay them on the bench face edge upwards; draw a line $\frac{1}{2}$ in. from the left-hand end, measure off 6 ft. 2 in., draw another line across, and you have the extreme width of your sashes marked. From these lines (A, A, Fig. 2) measure off at each end the width of the stiles ($3\frac{1}{2}$ in.), and square across the marks (B, B, Fig. 2) again; from these last marks measure outwards towards the ends of the rails $\frac{5}{16}$ in., and again square across your marks. These last marks (C, C, Fig. 2) are those you square over the sides for the shoulders of the tenons, and you will notice that, unlike the shoulders of the previously described window rails, both sides are alike, thus forming a square shoulder; the reason of this is that you may have a deeper rebate for the glass, which is an advantage in roof-lights, as it gives a better bed, and tends to prevent leakage. Before, however, you begin to square your shoulders over you must divide the rail into five equal parts, and draw the mortises for the bars. These mortises are $1\frac{1}{2}$ in. long; you had better keep them a little tight, say $1\frac{3}{16}$ in., as loose bars are an eyesore to the good workman. Let the two centre bars be mortised through the rails; the other two merely require letting in about 1 in.

The sole rails, which are next in order, are drawn across the top edges in a similar manner to the top rails, the same mark being taken for the shoulder (C, C, Fig. 2), which on these rails is only on one side—that is, the underneath one. You need not do your measuring over again; it is easier, and also more accurate, to lay a top rail on your sole rails and mark off the various points for shoulders and mortises. You cannot use your mortise-gauge on these rails for the tenons, so you must set a marking

gauge to $\frac{5}{8}$ in., and run it from the back of the wood, which ought to be accurately thicknessed to $1\frac{5}{16}$ in. The mortises are also different, as will be shown presently.

The bars are cut with a square shoulder at the top end, the lower end being cut as in Fig. 3. A $\frac{5}{16}$ mortise into the rail about an inch is sufficient. Of course, you must allow the $\frac{5}{16}$ longer at each end for the mitring into the mouldings of the rails.

When all the stuff is set out, mortised, and tenoned, it is rebated and moulded in the usual way; the rebate, as before mentioned, is of the same depth as the moulding, and this must be seen to carefully, for if both are not of the same depth the joints will not be close on both sides of the work when down through them. Nail the ends of the other two bars in the same way, cut off the stumps of the stiles and tenons, and plane up all round, and your roof-light is finished and ready for putting in place.

I have said nothing about the wood to be used, as that depends on the ease with which it can be got, and the amount of money to be expended. Yellow deal is easily worked; red deal and pitch pine are much preferable, but more expensive, and in remote places are sometimes not easily procurable; but whatever wood is used let it be as free from knots as possible, and I would say avoid using white pine if you can help it.

Two coats of white-lead or other priming paint had better be given the roof-lights ends of the bars, which are generally put into mortises in the top rail, the lower end being rebated into the sole rail, and nailed firmly down. In some instances the rafters themselves are utilised as bars, and rebated on the upper edge for the reception of the glass, the top and bottom ends of the panes being rendered water-tight by an arrangement of lead or zinc. In fact, every locality and every builder have different ways of doing the work, differing, however, only in minor details, the principle being the same throughout; so that the worker who masters the construction of the roof-lights described in this paper will have learned a useful lesson, and once having grasped the general idea of how the work is done, the alteration

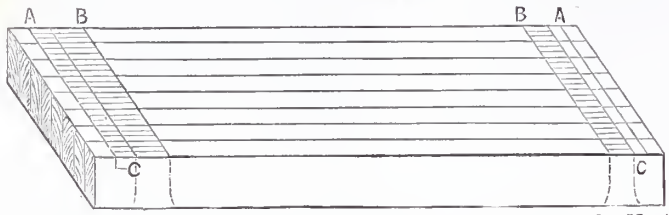


Fig. 1.—Stiles laid on Bench for setting out and showing Markings for Mortises.

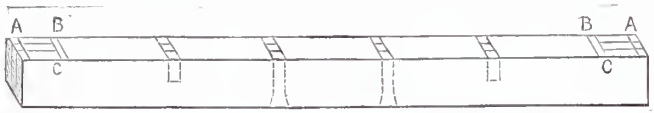

Fig. 2.—Top Rail set out showing Mortises and Tenons.

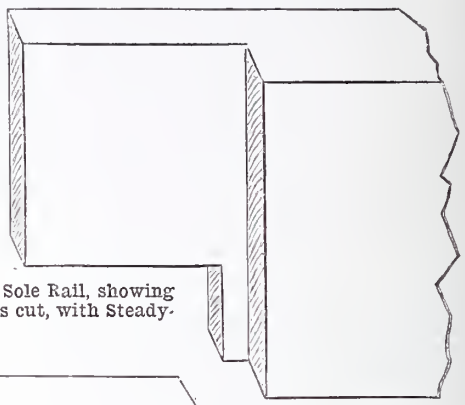

Fig. 6.—End of Sole Rail, showing how Tenon is cut, with Steadying Piece.

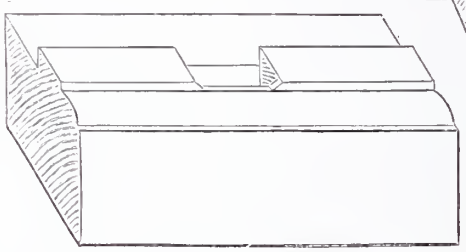

Fig. 5.—Diagram showing Mortise with Mitre to receive Top End of Tenon.

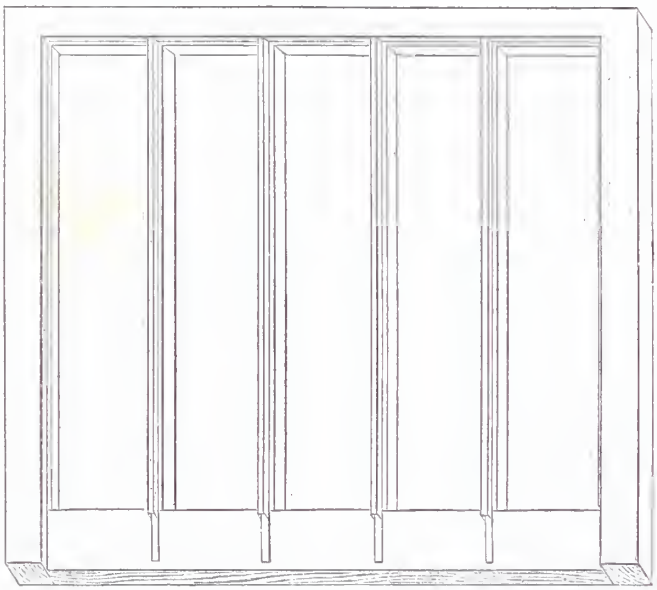

Fig. 7.—Roof-light completed.

Fig. 3.—Section of Sole Rail, showing Mode of mortising and fixing.

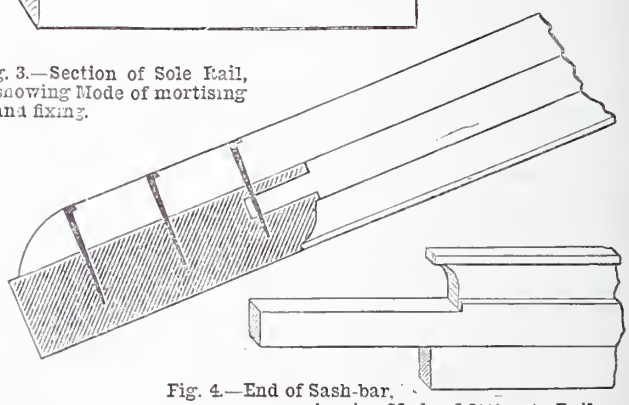

Fig. 4.—End of Sash-bar, showing Mode of fitting to Rail.

finished, and may give rise to twisting of the sash, or breaking of the tenons under the cramping-up pressure.

The mode of mitring the rails and stiles is the same as in the previously described dead-light; the bars, however, are a little differently managed, as will be seen by referring to Figs. 4 and 5, which show the end of a bar cut and mitred, and its corresponding place in the rail. The upper edge of the sash-bar, it will be noticed from Fig. 3, runs over the sole rail, and terminates within $\frac{1}{2}$ in. of its lower edge, where it is rounded off. This rounding should be done after the sash is cramped up. When putting the framing together, wedge up and pin the stiles in the usual way, then reverse the cramp by laying it across the rails in the centre. Wedge up the tenons of the two bars that go through the top rail, also pinning them, and nail the lower ends down firmly to the sole rail by driving three $1\frac{1}{4}$ in. stout brads before they are put in position; they can then be glazed and have a finishing coat of paint. Of course, the priming can be done if necessary when they are up, but it is a much easier operation to do it while they are on the ground and easily got at.

Forcing-frame sashes are made in the same way as roof-lights, but generally on a smaller scale, and no moulding need be worked on them; in fact, it would be lost labour to do so, therefore the under sides of the framing can be left square, allowance being made for that in the shouldering of the tenons.

In making long stretches of roof-lights, such as in nursery greenhouses or on factory roofs, a different mode of structure is adopted; the top and bottom rails running the entire length of the roof are fastened to the rafters, and the stiles and bars fitted into their several places *in situ*. Mortising and tenoning are dispensed with, except the top of minor details to suit any particular requirements is only a matter of thought on his part. In a future paper I will endeavour to deal with some of the intricacies of window making of a more complicated nature, and show how to put together a hung sash with its case.

## MAKING THE BEST OF A BAD HOUSE.

BY MARK MALLETT.

THE STUDY: WOODWORK OF THE FIREPLACE—OLD OAK — INCISED CARVING — THE CHIMNEY CORNERS—THE OUTER MANTELSHELF.

*The Study: Woodwork of the Fireplace.*—When the mason had set the grate and (under my direction) fixed the tiles round it, he was, I found, much exercised

in his mind as to the possibility of my ever making my fireplace presentable. His trade traditions as to the way in which things ought to be done had been outraged, but for my own part I saw no special difficulties.

First, round the tiles I fixed a casing of ebonised pine, and on its face a strip of moulding, the inner edge of which projected just so far as would cover any inequalities in the edges of the tiles, for, being an odd lot, they did not, of course, finish in a straight line. This casing projected some

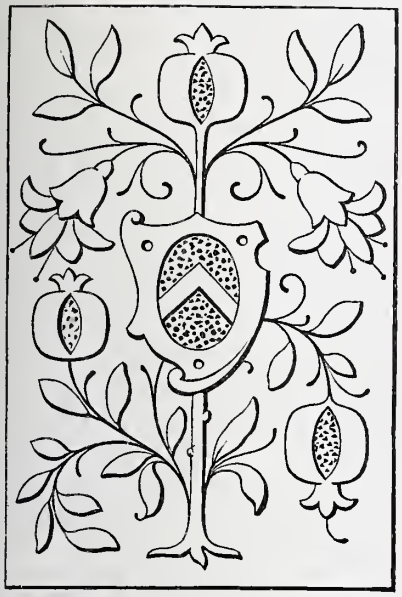

Fig. 5.—Panel: Pomegranate Conventionalised.

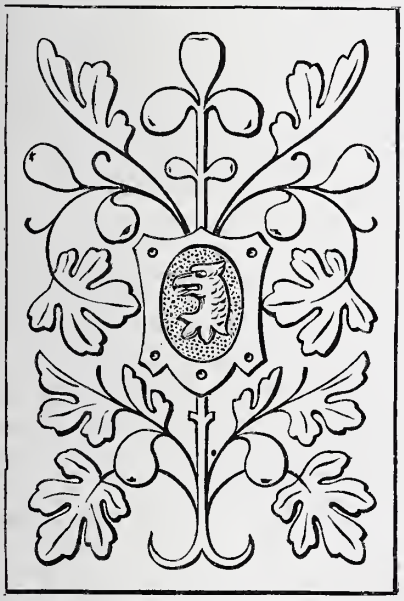

Fig. 6.—Panel: Fig Conventionalised.

3 or 4 in. from the wall, but I did not, as will be seen from Fig. 1 (page 449), rest my mantelpieee immediately upon it. Over it I arranged the groups of brackets shown, and rested the shelf on them. This gave me some handy little nooks, useful for laying things, beneath the shelf. In Figs. 2 and 3 the brackets are enlarged; they, like the mantelpiece itself, and the casing of the chimney-breast on each side, are of ebonised pine. Above the mantel-shelf all is dark oak. Ebonised wood, be it remarked, goes well with the colour of old oak. In this room a great many odds and

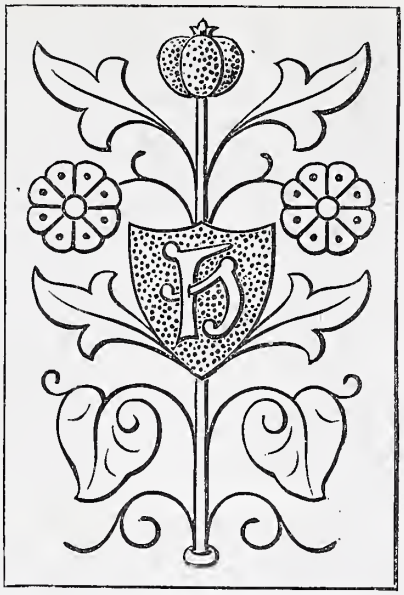

Fig. 4.—Incised Panel for Mantelpiece.

ends of the last-named material are used up, but to have employed new oak to supplement them in every part would have been a costly and difficult matter. I therefore eked them out with the more cheap and easily worked wood, and this wrinkle of my own finding out I can commend to others as worth their consideration. I ebonised with decoction of logwood chips, used hot, and iron dissolved in vinegar, polishing with beeswax and turpentine.

*Old Oak.*—In the decorative work above the mantelpiece, the two demi-figures which occupy the sides are old Jacobean carving—part of the wreckage, probably, of some demolished bedstead—but the panelling between them, though old in itself, is of my own decorating. When I began my work on this house I had by me an accumulation of odds and scraps of old oak-work, some carved, but more without carving. In country places, when old houses are pulled down and churches "restored," it is easy, if anyone will keep his eyes open, and take care to be on good terms with such of his neighbours as are in the building trade, to get such matters for a mere old song. This I commend to the reader as another wrinkle.

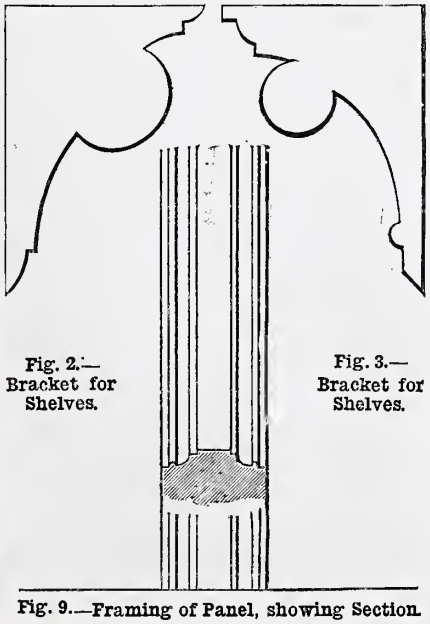

Fig. 2.—Bracket for Shelves.

Fig. 3.—Bracket for Shelves.

Fig. 9.—Framing of Panel, showing Section.

But to return to the overmantel. The decoration on the panels in question consists of little more than incised lines, a kind of work about which I should like to say a few words.

*Incised Carving.*—When setting about the decoration of a whole house, or even of a single room, the amateur wood-carver finds the need of quicker methods than when merely ornamenting some small fancy article, and in the manner before us a number of panels, whether new or old, may be enriched in a comparatively short time. In

Fig. 7.—Panel: Grapes Conventionalised.

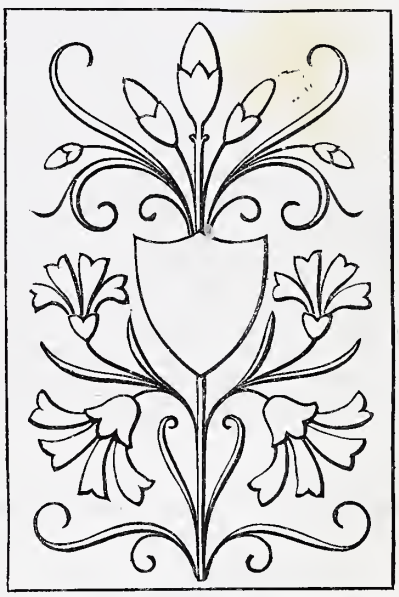

Fig. 8.—Panel: Carnations Conventionalised.

Fig. 4, one of these panels is shown drawn to a larger scale. Except where, as on the shield, the grounding-punch is used to give the effect of relief, almost the entire work is done with the dividing-tool. For this purpose I find that a leaden dummy drives the tool best. A very rough indication of the pattern only is required, as it is easier to get a good flow of line with the tool than with the pencil. One can vary these lines so much in depth and strength as to put a great amount of expression into them.

The design of Fig. 4 is very much a fanciful one, but in Figs. 5, 6, 7, and 8, I have designed other panels which the reader may

like better for carrying out, and in which natural growths are conventionalised; Fig. 5 is the pomegranate, Fig. 6 the fig, Fig. 7 the grape, and Fig. 8 the carnation. In Fig. 7 the grapes will better be defined with a gouge than with the dividing-tool.

*The Chimney Corners.*—The panelling which lines these is old stuff: the diamond pattern with which the panels are worked was a favourite one in early Stuart times. So much of the panelling as appears in Fig. 1 is a portion only of a large piece of wainscoting, which I got from a builder at the pulling down of an old house for 5s. Below this panelling appears a base of plain, ebonised wood, which does not assert itself in the drawing, but in the actual thing throws up and sets off the carving remarkably well.

To the left will be seen a corner-seat, with a carved front. The actual seat is one solid block of stone, which I have thus cased. What is now its front served as the front of a box in the days of James II., but came to me as a fragment with other fragments. The footstool below, I may, for the benefit of fellow-smokers, mention aside, is a disguised spittoon. On the jamb to the front of the seat another adaptation of old wainscot may be seen. In this the gouge-work at the top only is of the date of the panels, the lower carving having been added by myself to match the old work in the corners.

*The Outer Mantel-shelf.*—Over the wide opening to my old-fashioned hearth ran a huge, unsightly beam, which had, in the course of ages, been plastered over with innumerable coats of white and coloured washes. Along its front was nailed a mean, painted shelf, such as one commonly sees in such situations in farmhouse kitchens, the acknowledged receptacle for candlesticks and similar matters. This shelf I removed, and, having scraped and cleaned the beam, I bevelled off its front edge, planed it, and rubbed it over with boiled oil. It was of elm, but, through age and smoke, showed, when dressed, scarcely lighter than my old oak. Against it, but some inches higher than its predecessor, I fixed a new shelf of ebonised pine (as seen in Fig. 1). It is supported by brackets similar to those shown in Figs. 2 and 3, and between them are carved shields, with armorial bearings. For these last, which can be applicable in my own case only, I have in the drawing substituted fanciful devices of sun, moon, and stars. All the woodwork of this shelf, except the shields, was screwed together before fixing up; it was then screwed to the beam and the screws hidden by the shields.

## HINTS ON THE STRINGING OF THE ZITHER.

BY AN OLD TEACHER.

As R. F. has given us a splendidly lucid set of instructions as to how to construct a zither, it is a pity that he has not adhered to the conventional form of the solo instrument, especially as his dimensions appear to be exact for that description. The straight and ungraceful shape he gives is that chosen for the "Élégie," or "song" zither, or for the so-called "concert" zither, while the "Schlacht," "Horn," or "Prim" zither—which is the most serviceable one for general use—is infinitely more graceful, as well as offering greater resistance to the stress of the strings, which, it need scarcely be said, is very great.

Fig. 1 gives the "Élégie" zither, which will be found to coincide with the one given on page 392; while in Fig. 2 I give the alternative shape—that of the "first," or solo zither. Now, there are probably many persons who already possess a zither; it may be without strings, and as there are comparatively few persons capable of stringing such an instrument, my remarks will, perhaps, be of service, especially as I have played the zither in all its forms ever since its first introduction into this country, many years ago, while as a teacher my success has been exceptionally great, for reasons which will be seen anon. Whether for a zither *in esse* or *in posse*—whether it already exists, or still has to be made—I will guarantee that, if my instructions are followed, there will not only be no mistake, but that the tone (always supposing you have got a sound instrument—one not cracked) will be much in advance of any tuned or strung otherwise.

Firstly, I should premise that there are two methods of stringing in vogue, viz., the Stuttgart and the Vienna methods. Fig. 3 represents the finger-board, or rather the open notes of the melody strings (those five

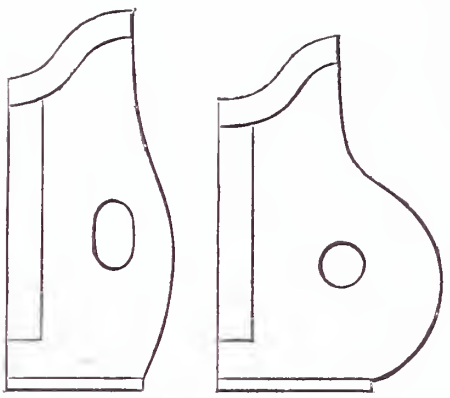

Fig. 1. Fig. 2.

**Fig. 1.—The "Élégie," or Song Zither, used as an Accompaniment. Fig. 2.—The "Horn," "Schlacht," or "Prim" Zither; the Solo Instrument, and the only one useful for Characteristic Zither Music.**

on the finger-board), of a zither strung on the former system, while Fig. 4 gives the Vienna method, which is the one most universal. And let me also add a word of encouragement to such as may possibly be deterred by the difficult look of the zither, with its numerous strings. I am aware that many so-called "instruction books" start off with, "The zither is a most difficult instrument, but," etc. Believe them not, they are fooling thee, as I, perhaps, should if you were going to give me a guinea per lesson, which is no uncommon fee for tuition on this most simple of instruments. I have myself received 5s. per hour for teaching it, but have always impressed the above fact upon my pupils. And the best proof that I am right lies in the fact that in the Tyrol, which is the home of the zither, it is played by "all hands"—men, women, and children. Again, anyone of ordinary intelligence may learn it in a week, although proficiency will only be attained by persistent practice. All there is to be learnt—that is, the methods of fingering with each hand, and the position of one major chord (which is all that there is to learn, as all others are exactly the same relative distance apart, and may be found mechanically)—may be written in the space of one sheet of Work. Therefore, be ye not dismayed, but persevere, and you may play pleasingly and correctly in a month; if you want to do fireworks and other feats you will have to practice long and often, but that is not zither playing proper. The great sympathetic charm of the instrument lies in its capacity for conveying feeling, which must first exist in the soul of the player. For my own part, I do not profess to be a great performer, but I can have a room full of people in tears in no time. That is how the zither should be played. Before going on to describe the best method of stringing, I may say that, should anyone be desirous of trying my simple method of learning, I may be communicated with through the "Shop" pages, although I no longer teach professionally. And here a caution to such as buy their zither. When you get it, it will probably be useless, having, in nine cases out of ten, been strung with silk and gut strings, which are not only worthless as to tone, but which will keep you fully employed in trying to tune your instrument—one of the most hopeless of operations when such strings are used. Take it as an axiom, then, silk and gut strings are, for the zither, worse than useless. On the other hand, I have had instruments in daily use for weeks together without requiring more than a casual or occasional touch—certainly they have never wanted tuning throughout. Procure good metallic strings, which are to be had in sets, in boxes. Beware of the music-seller who promises to "get them," or to "make them up," he is a fraud. Such sets of strings should not cost more than 8s. or 9s., at the outside, although a well-known maker once charged me 17s. for a set. I am aware that they are not to be had except of such as import them direct from Germany, but, having got them, they will last you three years, unless your hands are very moist in their nature, when, of course, the strings gradually rust under the wrapping, and the tone suffers, not the string. I wish it were possible to contrast the tone of the silk and gut with the steel in the pages of Work. What a convincing proof that would be! But string a fiddle with worsted, and you can guess the difference.

The sets mentioned do not, as a rule, include the steel and brass wire for the three first melody strings, but the fourth and fifth—that is G and C—both metal covered with metal, are included. Also, you may find in the set (each separate string having its number and note on a label) more strings than you have accommodation for. This is because a zither may have any number of strings, from twenty-two to thirty-two. Simply start at E flat (having first strung the finger-board), no matter whether numbered one or two. Some sets give G sharp as the first of the accompaniment strings. Don't use it if you find it so—you lose by it. As for any there may be over, simply discard them; they are not required for their legitimate place, but come in useful when you chance to break a string of similar calibre or gauge—an event which need never happen if care is taken to strain each string slowly and carefully, using frequent friction along its length in the process. Never string right up all at once, many strings "go" in this way. Make it a two days' job, and strain well before finally fetching up to pitch. Never go higher than half a tone lower on the piano, unless you wish to accompany another instrument, which zither players are, as a rule, not fond of, except in the case of such instruments as the guitar or mandolin, which can always be made to accord with the more delicate

zither. Having procured your strings, including a reel of each, steel and brass, which are sold specially, and cost about 6d. per reel, cut off about three or four inches of steel wire more than the length of the instrument from tail-piece to pegs. Then, with suitable pliers or your fingers, form a very small loop at one end, the smaller the better. Pass this loop over the pin at the

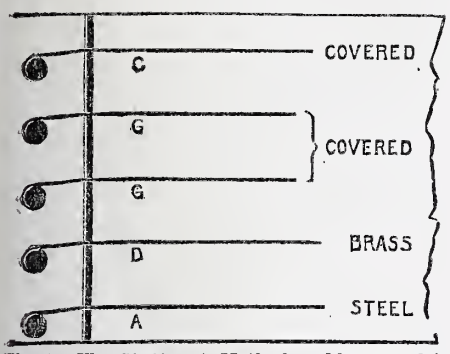

Fig. 3.—The Stuttgart Method, seldom used in England. The Strings bracketed are tuned alike.

tail-piece end and the string up through the groove in the latter. Then run the string through the finger and thumb of the right hand, so as to have it perfectly straight and free from "kinks." Insert not more than 1 in. through the peg-hole, and, with the tuning-key, wind the string evenly on the peg, using the right elbow to keep the looped end from springing out of the groove, or off the pin, and the right hand to guide the string evenly on the peg. When the string just "bites," and there is no fear of its springing out of place, leave it and pass on to the next, taking care in each case to pass the top of the string behind the little pin behind the nut (see Fig. 1, page 392).

When you have got on the three wire strings, you will find all others already provided with proper loops, which only want looping on to the pins and through the groove, but take precautions against twisting and "kinking." Also be very careful in unwrapping each string, as any actual bend in a string would probably result in a break.

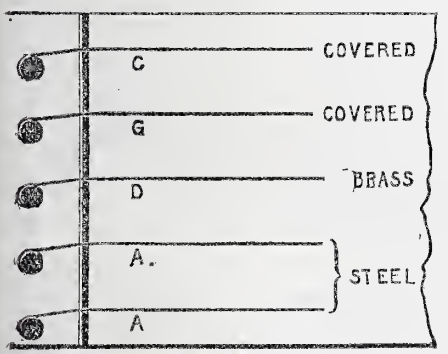

Fig. 4.—The Vienna Method, the one in Ordinary Use. The Strings bracketed are tuned alike.

Having got all the strings on, proceed to raise them carefully, beginning at the first. Fetch that one up to about E (under the stave) by the aid of a pianoforte or tuning-fork. Similarly with the next, which also has, eventually, to come up to A. Fetch the brass wire string up to about B, and so on, straining carefully each string. Now leave to stretch all night, after which proceed to tune the second string to A, then the first to it. Then place the forefinger of the left hand behind the fifth fret (where the first spot is) and tune the brass string to it, but an octave lower. Then stop the D string on the fifth fret, and tune the G to it, and the same with the next, which is C. Then your finger-board is complete, and in tune. Now comes the turn of the accompaniment strings, which comprise the first twelve after those on the finger-board. Tune these according to the following diagram :—

| *Number of String.* | *Name of Note.* | *How to form it, to tune to.* |
|---|---|---|
| 1 | D sharp | On the first fret of the D string. |
| 2 | B flat | ,, third ,, G ,, |
| 3 | F | ,, ,, ,, D ,, |
| 4 | C | ,, fifth ,, G ,, |
| 5 | G | ,, ,, ,, D ,, |
| 6 | D | By the open D string. |
| 7 | A | On the second fret of the G string. |
| 8 | E | ,, ,, ,, D ,, |
| 9 | B | ,, fourth ,, G ,, |
| 10 | F sharp | ,, ,, ,, D ,, |
| 11 | C sharp | ,, sixth ,, G ,, |
| 12 | G sharp | ,, ,, ,, D ,, |

Now all the work is done, as the thirteenth string is tuned an octave lower than the first, the fourteenth than the second, and so on throughout. Some strings in the bass, which begins at the thirteenth, are usually tuned two octaves lower—such are C and D sometimes—but you will easily recognise these by their greater thickness, and the utter impossibility of getting them up another octave. Don't try. Thus far the tuning. As to the proper position of the hands, etc., in playing, I should be very glad to write another article on that, but I am afraid the Editor has had enough zither MS. By the method I have given anyone may easily string up a zither, and do it properly, too, while, by attending to the hints I have given respecting choice of strings, etc., you can ensure having your instrument as nearly perfection as a very perfect instrument like the zither is capable of.

## SHORT LESSONS IN WOOD-WORKING FOR AMATEURS.

BY B. A. BAXTER.

### The Plane.

A few lessons in wood-working being desired by some readers, I will, without further preface, begin.

The use of the plane should be attempted before any other tools are studied. If the beginner buys a new jack-plane, and he can get the tool merchant to sharpen and set it while the buyer waits and watches, let him do so; but if so valuable a lesson cannot be had, try to sharpen it as follows :—

Knock out the iron. This may be done by grasping the plane, turned upside down, with the right hand, while the left holds the wedge and plane-iron. A gentle blow on the bench should leave the iron and wedge in the beginner's left hand. Do not drop them, which you will do if you hold them carelessly. The cutting-iron is now to be separated from the cap-iron by loosening the screw with a screwdriver. The safe way of doing this is to hold the iron on the edge of the bench, the screw just off, but close to, the bench edge. To sharpen the plane, rub firmly but gently on a clean oil-stone on which is a little oil. (For a lesson on Sharpening, see WORK, Vol. I., page 310.) Be careful to put the plane together as the maker intended; beginners do not always do so.

It is important to learn to set the plane by the eye, so that without trying the plane and going through that unsatisfactory process of tapping and withdrawing the iron, you become able to place the iron so that it will take off a shaving proportionate to the hardness of the wood and the strength of the operator. I should advise the beginner not to attempt to use a plane the iron of which projects more than the thickness of the paper on which this is printed. He can afterwards remove stouter shavings, but some considerable experience in teaching prompts me to lay stress on this matter.

Another little point on which a warning is necessary: in placing the cap-iron and the cutting-iron together, do not let their edges pass each other, or the newly sharpened edge will suffer. Sometimes in screwing together this will happen; if so, it is usually because the head of the screw touches one side of the iron before the other. As the screw is generally accurately turned, the fault may be in the boring of the brass nut which is fixed to the cap-iron, or it may be in the cutter-slot being thicker at one edge than the other, or some roughness in the slot, or the whole cutter or cap-iron may be bent or winding. Whatever the cause, find it out, cure it, or change the iron, for there is nothing more trying to a beginner than having with care sharpened the plane-iron, and find, to his annoyance, that in the screwing together of the two irons the cap-iron passes the sharpened edge and spoils it.

## KNOTTING, SPLICING, AND WORKING CORDAGE.

BY LANCELOT L. HASLOPE.

### Some more Fancy Knots.

Single Pitcher Knot—Pitcher Handled—Double Pitcher Knot—Slinging a Can—Shamrock Knot—Dalliance Knot—Davenport Brothers' Knot—Bell-ringer's Knot.

Fig. 98 is the "Single Pitcher" knot, known also as "Tom Fool's" knot. The easiest way to make it is to form two half hitches, as shown in Fig. 99, one lying half-way over the other. With the finger and thumb of the left hand draw the part A down through the bight, and with the same fingers of the right hand bring the strand, B, upwards through the bight, under which it lies. Pull the loops thus formed out to a sufficient length and knot the ends together. When used to supply the place of a broken pitcher handle, the centre knot should be hauled taut, and the pitcher being placed on it, the loops are brought up to form handles. To keep them in their places a lashing is put round the neck of the pitcher, as shown in Fig. 100. This knot is also very useful in slinging a shot when required as a weight, or for any other purpose. In this case the centre knot is not hauled taut but left open, forming a large loop on which the shot lies. If the ends are spliced instead of knotted a three-loop knot is made. It is also used as a trick knot to puzzle landsmen, and from this arose its name of "Tom Fool's" knot. To make it in this way, turn the left hand with the palm upwards and lay one end of the cord across it, holding it against the side of the hand with the thumb. Turn the right hand over so that the backs of the fingers are downwards and the ends of the fingers pointing towards you; take up the other end of the cord on these fingers, but do not close the hand; bring the right hand, without altering its position, over the left, until the part hanging down over the first finger of the right hand hangs outside the left hand. With the third and little

fingers of the left hand seize the cord which hangs down over the little finger of the right hand, and at the same time with the right thumb and the other fingers of the same hand take hold of the cord which is on the left hand. If the hands are now separated the knot will form.

This is a good puzzle, as from one hand lying over the other as the knot is made, it is impossible to see that one end is grasped between the third and little finger of the left hand, even when the knot is made slowly and with every apparent intention of showing how it is done.

Fig. 101 is the "Double Pitcher" knot.—This also goes by the names of "Jury" knot and "True Lovers'" knot. It is used as the single pitcher knot to sling a broken pitcher, but in this case we have four loops to carry it by instead of two. In rigging a jury-mast the end of it is put through the centre of the knot before it is hauled taut; the stays to support and steady the mast are then made fast to the bights of the knot. It is called, I believe, a true lovers' knot because there is no end to it. Form two half hitches in a piece of cord, as in Fig. 102, then make another hitch, which draw behind the other hitches with the inner edge overlapping the inner edge of the first hitch, as shown in Fig. 102. Pass the forefinger and thumb of the left hand over strand A under B and take hold of C. Put the same fingers of the right hand under D over E and take hold of F. Take G between the teeth and draw the three loops out. It is better to make G the length required at first, as the other loops being immediately connected with the ends can be more readily adjusted as to size than the upper loop. When the loops are made the right size the loose ends are spliced together with a short splice, thus forming the fourth loop. The knot is now completed.

Fig. 103 is a ready way of slinging a can which comes in useful for a variety of purposes, such as turning a meat can into a paint pot, dipping for water, etc. etc. Pass the end of the cord under the bottom of the can and bring the two parts over it, and make with them an overhand knot; open the knot, as shown in Fig. 104, and draw the two parts down until they come round the upper edge of the can; haul taut, and knot them together again over the can, as shown in Fig. 103. This is a very useful dodge.

Fig. 105 shows an ornamental knot that was discovered by a correspondent of the *Queen* newspaper hanging below a Japanese lamp. It has been named the "Shamrock" knot. Of course the ends could be spliced, thus forming a four-looped knot if required. Whether it is ever used in Japan otherwise than for ornamental purposes I cannot say, though it is evident that it is available for the same uses as Fig. 101. It is not, however, as good a knot as the other, being more troublesome to make and not so strong, in consequence of the short nip of the strands in the centre of the knot. Fig. 106 shows the way of making it. An overhand knot is first formed with the ends at A; the end B is then laid across the upper loop, brought round and under the right loop and up through the bight C. The strand D, after passing at the back of the upper loop, is carried over the left loop and down through the bight E. The loops are now adjusted for size and the knot hauled taut. Fig. 107 gives another way of making this knot. Two overhand knots intersecting one another are made on the ends, as shown in the figure; the part A is then drawn up through the bight C, and the part B down through the bight D. These form the side loops, and the top loop being pulled out, the knot is completed. By an extension of these methods knots may be made with any number of loops, but the difficulty increases greatly as the loops increase, so much so, that many loops cannot be made without wire is used instead of cord. As this would lead us beyond the scope of these articles, I shall leave the matter to my readers to follow out by themselves, if they deem it worth their while.

*Dalliance Knot.*—This is a trick knot, and rather a difficult one to learn when you merely see it rapidly made. The object is to make two double knots, quite independent of one another, at once on a double cord. Double the cord so that the ends lie together; bring the bight over the standing parts, as shown in Fig. 108, and cross the strand A over the strand B; they will now appear as in Fig. 109. Press the part C down between the two strands on which it lies, and bring it up through the opening D, draw it out, and two overhand knots will be formed on the double cord. While the part C is being drawn out through D, the whole of the loop E must be brought up through the bight F; this forms the upper knot. The lower knot is made by loop F, C forming bight at top of double cord. The finished knot is practically the same as Fig. 16 (page 137).

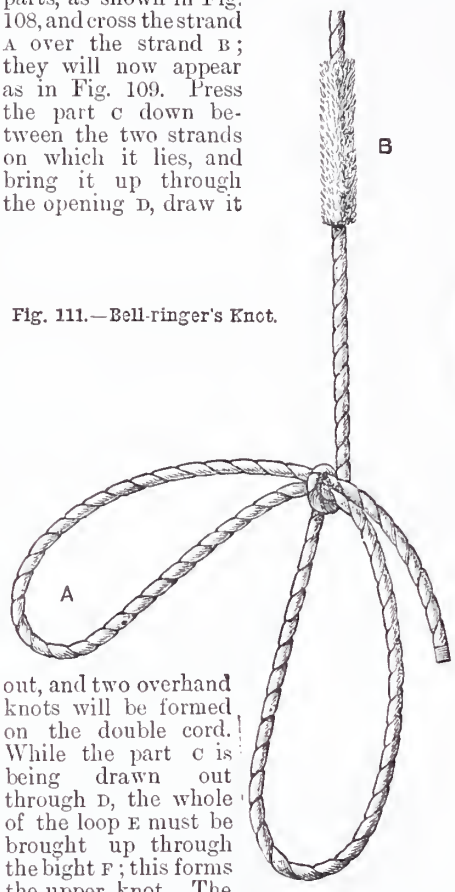

Fig. 111.—Bell-ringer's Knot.

Some of my readers will doubtless remember the performances of the so-called Davenport Brothers some years ago. These consisted of various tricks performed with ropes. In the principal one the performers were shut up in a cabinet, and when the doors were thrown open they were found seated on two chairs tightly bound hand and foot. Any amount of examination of the ropes and knots was allowed. The moment after the doors were closed they rang bells, played on the tambourine, and threw things out of a small window in the top of the cabinet. On the doors being opened again directly they were found firmly tied to their chairs as before. They claimed to effect this by spiritual agency, whereas their only assistant was an ingeniously contrived knot, which is shown in Fig. 110.

To perform the trick, two ropes about 12 ft. long each are required; they should not be too stout—the kind used for cording boxes is as good as any. First the knot A joining the two ropes must be made. This is an openhand knot, shown in Fig. 8 (page 65), the ends being passed twice through the bight to increase the size of the knot. Two running knots are now made close up to this knot as shown at B, B. The knotted end of the ropes is laid on the seat of a chair with the ropes passing down the back of the seat and under the chair. The performer seats himself on the chair, and, drawing the loose ends of the ropes up in front from under it, he passes them round and round his legs and the legs of the chair in as complicated a manner as he can devise. He now draws the knotted end from under him, and, putting his arms over the back of the chair, passes his left hand *down* through one loop and his right hand *up* through the other. He now turns his right hand down until the palms of both hands are together and the fingers pointing downwards. This produces a twist in the ropes which takes up the slack and tightens the cord round the wrists. The large knot being between the hands effectually hides this, and the wrists merely appear to be as tightly bound together as they can be. The performer has merely to reverse this last proceeding—that is, to bring the right hand up again, and so undo the twist—and his hand can be withdrawn as readily as it was put into the loop. The trick requires some practice, and the size of the loops must be regulated by the size of the performer's wrists. The knots should also be so placed on the chair at the commencement that the ropes are tight when the hands are in the loops. Of course, they can be tightened by the performer leaning forward, but it looks better and puzzles the audience more if the actor is so bound that he cannot move in any direction. The Davenport Brothers used also to perform the ordinary rope trick, which consists of the performer being bound by any of the audience; he is then covered up, and when, in a few moments, he is uncovered again, he is found to have freed himself from the cords with which he was tied. This is done by expanding the chest and making the muscles as rigid as possible whilst the tying is going on. When the muscles are relaxed there is not much trouble in slipping off the rope, particularly if it is a new one. The Davenport Brothers were checkmated in this trick by some Liverpool gentlemen securing their hands with a Tom Fool's knot, and also on another occasion by tying their thumbs together behind their backs with whipcord. There is no better way of securing a man than putting his hands into the loops of a Tom Fool's knot and knotting the ends securely behiud his back. It is much safer than using the ordinary handcuffs.

Fig. 111 is the "Bell-ringer's" knot.—I give the name by which it is commonly known, although it is a hitch and not a knot. Church bells have a large wheel on the axle on which they are hung, round which the bell-rope passes; this is done to obtain sufficient leverage to raise the bell mouth upwards when it is rung. This requires a long rope, a good portion of which lies on the belfry floor when the bell is down. When the ringing is over this slack is always hitched up out of the way in the manner I have shown. A loop, A, is made near the end of the rope; this is laid against the standing part, and a hitch taken over it at about the height of a man's head. The hitch should be kept quite close to the standing part, and it will hold the loop quite securely; at

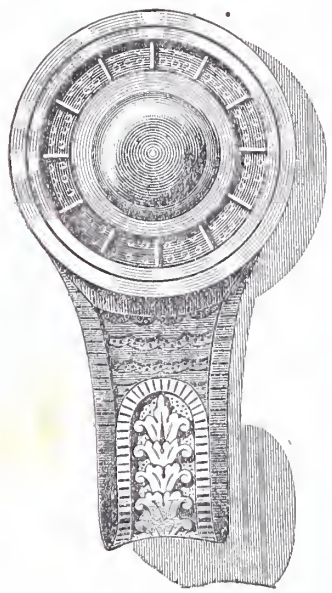
the same time a slight pull at the end releases the whole thing at once. When I was an amateur bell-ringer anyone leaving their bell-rope trailing about was subject to a fine. The part B where the rope is grasped when the bell is checked as it comes over is called the sally or tufting. It is made by opening the strands and inserting short pieces of worsted, which are afterwards trimmed until they are all of one length.

## A PICTURE SUSPENDER.

BY JAMES SCOTT.

It is as well, when hanging must take place, that it should be accomplished with adjuncts not too revolting; therefore, when a picture is about to be hung, the use of the most befitting attachments should be undertaken. A disreputable-looking nail protruding from a wall whereon is suspended a tolerably well-executed picture is a common



A Picture Suspender.

sight to behold in many households. Sometimes the nail may have a brass head, which fact in itself is sufficient to speak for the opinion which is generally held of a bare nail. Someone, however, has flown higher still in his estimation of what is necessary to support a picture. The outcome of his cogitations is represented in the illustration. The article is made of brass. The circular face consists of a removable embossed cap, which fits closely outside a rim which is raised around the upper circular portion of the hook. A hole is pierced in the upper circular portion of the hook to receive a nail which is to pass through it into the wall. Over the hook travels the supporting cord. Thus it will be seen that the nail, although unsightly, is yet indispensable. So it always is—the weakest to the wall. But it must not be forgotten that in this case the nail is weakest in aspect only.

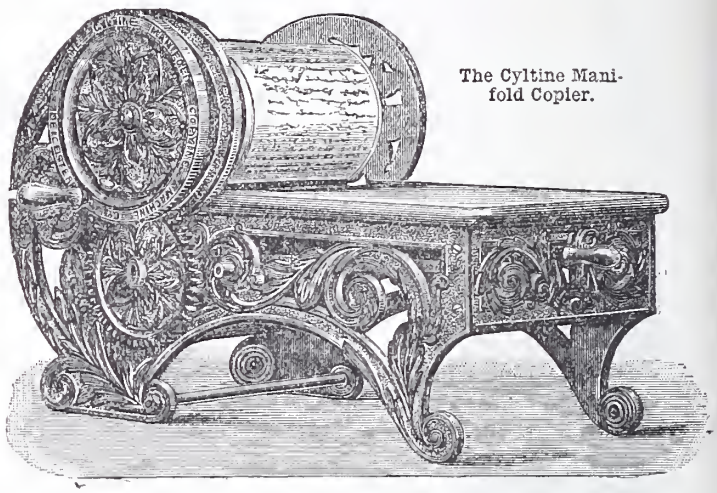
It may be pointed out that this picture suspender is merely an adaptation of the hook that is used for hanging pictures on a brass bar generally fixed a few inches below the cornice to the purpose of hanging a single picture. Its use is entirely a matter of taste and preference.

## OUR GUIDE TO GOOD THINGS.

*** Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

85.—THE CYLTINE MANIFOLD COPIER.

In the accompanying illustration will be found an excellent representation of a new lithographic copying machine for office use, well adapted for the reproduction of circulars, plans, notices, blank forms, shorthand, music, bills of fare, menus, quantities, instructions of special character, and, in short, for doing anything and everything in the shape of office manifold copying. It has been brought out by the Cyltine Manifold Copying Machine Company. As I have not seen a specimen machine, I can say nothing definite with respect to its working, but to judge from the specimens of work done by its aid which have been submitted to me, it appears to be a useful and effective appliance for office work, and one which all readers of WORK requiring such a machine would do well to inspect before making a final selection from the copying appliances already in the market.



The Cyltine Manifold Copier.

The Company claim for their copier the following advantages in addition to cheapness of reproduction after first cost: Originals are written with an ordinary pen with a free-flowing special ink, and can be copied without delay. Unlike the ordinary apparatus, made of wood principally, which may be moved from place to place, and, from its mobility, is liable to injury resulting from falls or other accidents, the Cyltine Manifold Copier is a permanent institution like the screw press for letter copying. It is the cleanest working copier, and the result, in jet black or any other colour, is equal to lithography. It will print to register on ruled paper. There is no hand rolling: turning the handle of the machine does the work. Sheets are fed into the machine from the mahogany board on the front, and are automatically printed and delivered straight as they go in, not curled or creased.

In order to use the machine to advantage, it is necessary that the operator should be "neat-handed"—that is to say, neither clumsy nor awkward in handling the machine and the paper on which the impression is received. All machines are sent out as they should be worked, with one exception—that is to say, the gelatine is dry, and it must, of necessity, be damped before the machine is in working order. To do this, the plated clips must be put on the gelatine before soaking, in the centre, and the dogs in the centre of the clips. Then water must be placed in the tray, and the gelatine scooped under the water, which has the effect of excluding all bubbles of air. The gelatine should be soaked in and under the water for twenty minutes, and when taken out should be wiped on both sides with a damp chamois leather. No other detergent will do. As soon as the surplus moisture has been removed, the gelatine has to be applied to the cylinder and secured by passing a screw through the dogs, the screw being tightened with a key supplied for this purpose. When the wrinkles in the gelatine have been smoothed out with the damp leather, and it is tight on the cylinder, the machine is ready for use.

The preparation of the copy is simple enough: as already explained, it must be written with the ink supplied by the Company for this purpose, and should be written on fairly thick paper with a smooth surface. When the ink is dry, the paper should be damped on the back and laid in a book for a minute to prevent it from creasing when it comes into contact with the damp gelatine. When applied to the gelatine, it must be fed up to the gripper stops, and when nipped, the paper must be folded over the gelatine and smoothed down with the right hand, so that the surfaces of both gelatine and paper may be brought into contact in every part. They should be kept in touch from half a minute to two minutes, according to the number of copies required. When the "copy" is taken off, the cylinder must be washed with wetted leather, which must then be squeezed out and again applied, to dry off.

The work of printing may now be started, but as when the gelatine was put on the machine and the copy placed on the gelatine, the ink rollers were disconnected by taking the springs off and drawing the brass roller back into the recesses, which had the effect of causing the compo roller to drop out of touch with the cylindor. Ink must now be applied from the tube that contains it here and there to the pad, and rolled up evenly with the loose brass roller. The pressure of the cylinder is regulated by the screw under the screw-board, but too much pressure should be avoided, and the nut locked after altering the screw. An easy, steady rotation does the best printing, and care should be taken to work the machine regularly and without exerting too much force, as this is likely to injure the stop against which the latch is brought. When the latch is at the stop is the time to feed the paper into the gripper. This done, press the latch to start, and make a clean circle back to the stop, then feed in another sheet, and so proceed until the requisite number of copies have been worked off.

The handle shown in front of the machine is used for throwing the cylinders out of touch when working up the ink on to the negative. In the ordinary way, the loose brass roller carries ink sufficient for from thirty to fifty copies; but when the work is large, more frequent inking will be required. When the machine is working, the brass roller at the back, carrying the ink supply, should stand in the recesses, and should only be lifted out and brought into contact with the compo roller when more ink is required. It must be borne in mind that when the cylinders are in touch a revolution should not be made without putting in paper to receive the impression, or the bottom cylinder will be printed. From the description of the manner of working which has been given, and the illustration of the machine, some idea may be gathered of its utility for the various purposes mentioned in detail above.

THE EDITOR.

## SHOP:

### A Corner for Those who Want to Talk It.

*** *In consequence of the great pressure upon the "Shop" columns of* Work, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### II.—Questions Answered by Editor and Staff.

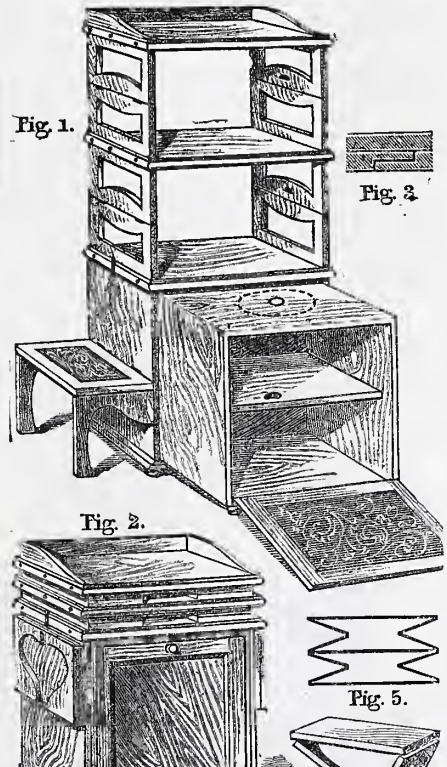
**Paint (for Art Ironwork).**—T. H. (*London, S.E.*), Amateur, and Others.—I believe the black known and sold in the trade as "Berlin black" would be the article you require for coating art metal work. Mander Bros., Wolverhampton, and most other manufacturers, make this: but only a few put it up in small quantities. Recipes for making flat blacks are given in Vol. I., and a little gloss could be given to them by adding a little more of the varnish or binding vehicle.—F. P.

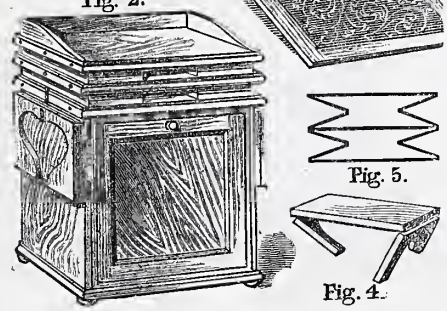
**Water Gold-size.**—S. H. (*Elmore*).—On p. 603, No. 38, Vol. I., you will find a useful *résumé* of the "water-gilding" process, and which, in justice to inquirers generally, I must refer you to. I should think, however, that you would more easily succeed in re-gilding the frame in question by stopping the cracks with either "white-lead putty" or distemper "filling-up," according to the nature and appearance of frame and cracks, then paint with sharp colour and size, and gild in *oil gold-size*. This, if done well, would have a good burnish, and last longer than water gilding, as the latter cannot be so easily washed or cleaned up. The oil-gilding method has been repeatedly explained briefly, but sufficiently for you, in Vol. I., which I hope, like all scnsible readers, you have bound up and ready at hand to refer to. J. Hill, of Pentonville, will supply gold-size, oil or water.—F. P.

**Blackthorn Varnish.**—M. C. (*Crossgar*).—Although unable to bring the experience of a specialist in "blackthorns" to bear upon your inquiry, I conclude it ought to be a good "*hard*-drying" varnish for coating them with. *Patent knotting*, or knotting composition—which is a quick-drying varnish—is used to a considerable extent for cheap umbrella handles and sticks, and it answers the purpose very well, drying hard in about half an hour. It can be made by taking the subjoined ingredients, placing them in a vessel, and dissolving with gentle heat:—1 quart vegetable naphtha, ¼ lb. oxide of lead (red lead), ½ pint japanner's gold-size, and about, but not more than, 1 lb. of orange shellac. Stir and well shake until quite dissolved, then strain through fine muslin. I think this should suit you, and would also do for the "barkless parts" if you spread it carefully with a camel-hair polisher's brush. Sorry I can't advise *re* the "burrs." I fancy if such are subjected to steam, they may become pliable, and can then be bent to shape desired, but have no personal experience to advise on this point. Our worthy Editor will doubtless appreciate the "model sword-thorn"—although I do not think he has so far found it necessary to keep a "fighting editor," and notwithstanding "Shop" contains an occasional "warm corner." Thanks for "good wishes," and, of course, *recommendation*.—F. P. [No, there is no fighting editor kept, as the Editor can do all that is needful in that line in any way for himself.—Ed.]

**Enamel, etc.**—Ibex.—I would have preferred to know the purpose and article the enamel is required for before advising you, but hope this will be useful. Firing glass is a risky method unless it is thoroughly understood and prepared especially with that object in view. For "backing" a piece of plate-glass which has been lettered upon and requires a white ground, I should advise coating it *very barely* once or twice with quick hard-drying paint, made with white lead (preferably, tube flake white), and either bath varnish and turps in parts one to two of the liquids respectively, or Japan gold-size and turps. When fairly solid, this could be finished with a little flake or zinc white (tube pigment) in the best light copal varnish you are able to get, made for interior work if your object is indoors, or using *bath varnish* if it is outdoor work. If you spread a white oil enamel directly on *smooth* glass it would probably, in time, peel off; but by using the "sharp" colour we get a "grip" or "cement" between glass and enamel, and likewise get a better body and solidity than enamel alone will give. Ready-made spirit enamels will not do; they will crack and peel off very quickly. Write Waterlow & Sons, Limited, Finsbury Works, E.C., respecting the "perforator."—F. P.

**Commode.**—C. B. (*Notting Hill*).—When your letter was handed to me, I had a paper in course of preparation dealing with a combined commode and clothes-holder, which I had designed as something fresh. Such an article is rather a delicate subject to appear in the body of Work, where it would, doubtless, possess a certain amount of repugnance; therefore, I will take advantage of your query and endeavour to explain it satisfactorily in "Shop." Space is limited, so I must speak briefly. In Fig. 1 the dotted line suggests a place for a necessary article which shall be nameless. At each side is a bed-step—carpeted. Hooks can be fitted to each of the top boards to hold apparel at night, in preference to its being thrown on to chairs, etc. When closing the article (seen by Fig. 2) the front flap is raised, the box then pushed into the main carcase, the supports of the bedstep folded inwards underneath the latter (Fig. 4), and the whole raised up against the side of the carcase, where they will be secured by means described later on; the two top sideboards are then folded inwards, as shown by skeleton diagram, Fig. 5. From this explanation it should be understood how and where the requisite hinges





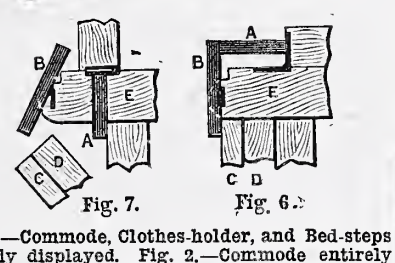


**Fig. 1.—Commode, Clothes-holder, and Bed-steps fully displayed. Fig. 2.—Commode entirely closed. Fig. 3.—Bed-step Supports overlapping each other when folded. Fig. 4.—Diagram showing how Bed-step Supports fold. Fig. 5.—Skeleton Diagram, showing how Top Parts fold. Figs. 6 and 7.—Movement to retain Bed-step in Vertical Position.**

must be fixed. When adjusting the top part the reverse movement will, of course, be necessary. Flush bolts in either one or both pairs of folding boards will keep them firm. When these boards are raised, if my description is carried out, each bed-step will fall into place independently of further handling—the supports tumbling down as in Fig. 4, provided the hinges work easily. If the height of each support exceeds a half-length of the bed-step, both supports must be made to close over each other as in Fig. 3. In Figs. 6 and 7 is shown the movement which will hold the bed-step in position when folded up. The outside long edge of the latter should just touch the underpart of the top board, and a small part of the top board's edge, exactly in the middle, will be cut flat to allow a short wooden bar (B) to be hinged to it. This bar must be wide enough to cover a portion of each support when folded (if their edges meet). Also in exactly the middle of the edge of the bottom folding sideboard will be inserted a short bar (A), sufficiently long enough to just touch the bar, B. In Figs. 6 and 7 C is a support, D a bed-step, and E the carease top board. When the top shelves are adjusted the edge of the bottom folding board naturally touches the top board (Fig. 7), and thus the bar, B, is released, and the bed-step and supports fall down by reason of their own weight. Now it is clear that the bar, A, will not pass through a solid board to assume the position in Fig. 7, therefore it is necessary to cut a small piece out of the top board to allow it to do so, remembering the while that care must be taken to leave enough to hold the hinge for the bar, B. It will be best to draw full-size sketches of this part at starting, for you will find it a "ticklish" job. Concerning the main carcase there will be a bottom board, top board, sides, and backboard. A strip of the bottom board will be united to the front of the bottom board of box. Four feet only will be necessary: two at the back and two in front, the latter cut in halves, so that one pair can remain on the main carcase while the other pair travel with the box. Read previous articles for joinery. Of course, you do not want to be told that you can dispense with the clothes-holder, and save a lot of labour thereby; and also have the top board as a lid, and no movable inner box; and you can also have the bed-steps fixed instead of to fold. For sizes, 16 in. square, 24 in. high (main carcase), and thicknesses ¾ in., ½ in., and some much thinner, will give you a foundation to work upon. You can have castors, but I do not advise their use.—J. S.

**Oil Varnish.**—C. A. (*Hackney, E.*).—The subject of making oil varnish, from some cause quite foreign and strange to those workers who use quantities of it, appears to possess some fascination for the general community, and for readers of Work particularly. I do not think any person, even were he professionally engaged in its manufacture, could give you a receipt for making "1 pint of the very best oil varnish." I would advise you to turn up Vol. I., and read on p. 659 all that bears upon the subject. Then turn to "Shop," p. 541 (same vol.), and read answer to a similar query. The receipt from Spon's "Workshop" vols. is about the most *unworkshop*—if I may so term it—direction that could be published on the subject, and fully bears out the observations of the great varnish firm, quoted on p. 659. Best oil varnishes are, almost without exception, made from *copal* gum—whether the house-painter's "*carriage*," so-called, at 16s., or the coach-painter's genuine carriage varnish, at 30s. to 40s. per gallon. You would therefore require some *copal*. The manufacturers buy gums in large quantities, and sort the light and dark according to their requirements. The light is the scarcest, and hence the dearest. "The *best* varnish" is only a comparative term, and all good varnishes are made for various conditions: some for outdoor work—elasticity; others for whiteness and "hand-polishing;" others, again, for quick and hard-drying qualities; and as all these conditions are effected and governed by the proportions and treatment of the ingredients, you have some notion of the difficultics in the way of making a pint of the best—for what purpose you don't say. Copal is a gum that is very difficult to properly dissolve in oil and turpentine, and to effect the dissolution it is very necessary to have special facilities of heating and special vessels for the purpose; so that even if you were given proportions for any varnish, the chances are still ten to one against your succeeding. "Bloom" is a fault that the best of varnish manufacturers have never thoroughly succeeded in mastering, and therefore how could a novice, with an odd pint, expect to succeed in this respect? whilst with small quantities the purchaser is always at a disadvantage. If any reader can oblige the working "British public" with such a receipt for a pint of best oil varnish that will stand proper tests, he will be their benefactor, without doubt; but as one who has the buying and using of hundreds of gallons a year, I should want to test it myself before accepting it. I will try to contribute a *useful* receipt later on.—Decorator.

**Furniture Firms.**—W. E. R. (*Penryn*). — So much depends on the class and kind of furniture that you want, that it is impossible to answer your question satisfactorily. Surely, if you are in the furniture trade you do not require to ask the names of wholesale firms. Of course, any wholesale firm will supply furniture "to the trade at trade prices." You had better refer to the advertisement pages of one or other of the periodicals devoted to the trade, and you might as well read the answer to Spot ("Furniture Frames") on p. 260 of Work, No. 68, Vol. II.—D. D.

**Chest of Drawers.**—F. W. (*London, W.*).—Your question is such a vague one that it is almost impossible to answer it satisfactorily. As you have only a limited quantity of wood, why not make the chest of drawers of dimensions to suit yourself, and not run beyond the wood you have? Assuming that a chest 3 ft. 6 in. wide is what you consider a middling size, make it 3 ft. 6 in. high, and 1 ft. 8 in. from back to front, or thereabouts, and you will not be far wrong.—D. D.

**Oak Chest Fittings.**—Joiner.—For suitable brass work for your bureau, apply to Grew and Bridge, Summer Row, Birmingham. As they are wholesale people, it is only as a matter of favour that they will supply you, as they probably will if you mention this Magazine. Of course, you can hardly expect them to charge you the lowest wholesale price for such a small quantity as you are likely to require. You might also try Melhuish, of Fetter Lane, E.C. It will be cheaper and better for

you to buy the brass work than to attempt to make it, as you are not accustomed to the work. Without knowing the design of your oak table, it is quite impossible to supply you with design of chair to match. A moment's consideration on your part would have shown you this. Send a drawing of table, and we will see what can be done to help you.—D. D.

**Xylonite or Ivorine.**—H. C. (*Birmingham*).—The maker's name and address of this substance have already been given several times in "Shop" as follows:—British Xylonite Company, High Street, Homerton, London, E.—D. D.

**Finishing Bookcase.**—POLYSMATTER.—There is no "best way" to finish within the limits you name. It is entirely a matter of personal taste whether you finish in natural colour, or ebonised, or walnut, or mahogany. I have never seen fluted glass used for the purpose you name. I do not think it would at all tend to improve the appearance of your bookcase. I decidedly prefer slides to support the writing-flap in a piece of furniture such as sketch shows yours to be. Flaps would be awkward. Their only recommendation is that you might find them rather more easy to make and fit. If you are a fairly skilful worker, though, this consideration ought to have no weight with you. You must please yourself about the use of gilt mouldings if you ebonise the job. You and many others may think them very handsome and nice, while I and many others are equally certain to consider them quite the reverse.—D. D.

**Polishing Counter.**—W. J. G. (*Caversham*).—If you used the beeswax and turpentine in a proper way, you ought to have got a fair amount of polish. I do not, however, consider polishing was at all suitable for such a counter as you name, because the polish is so easily destroyed by moisture. It is not necessary to fill in the grain when the work is to be wax polished, as the wax also acts as filler. If you had told us the kind of wood, and other particulars, we might have been able to tell the cause of failure. Inquiries cannot be answered privately through the post. Glad you find WORK of so much benefit to you in your trade.—D. D.

**Tool Chest.**—A NEW READER.—Tool chests are so varied in size and fittings, that it is quite impossible to devise one for you if you cannot do so yourself. You know your tools, I do not; so here, at once, you have an advantage over me. As you are a professional mechanic, surely you have ample opportunities of seeing other tool chests. Were you an amateur, I would give you hints, but to offer them to you would be superfluous, for you, no doubt, have your own ideas. As for the tools themselves, I hardly know what to say, but my opinion is that you had better ask your shopmates which is the best place in your neighbourhood to buy tools at. Of course, if all your mates are "puir feckless bodies" too, you can't depend on them; but if, as I take it, there is a canny Scot or two among them, you may as well put yourself under their guidance. Naturally, small ironmongers, as well as large, want a profit, and good tools are not to be bought at low prices. There is certainly a lot of rubbish in the market nowadays, and the way to increase its quantity is by grinding down the retailers' prices. Pay a good price to a respectable tradesman—I suppose there are some in Thirsk—and you will get good tools.—D. D.

**Ivory Carving Tools.**—T. J. B. (*Shrewsbury*).—You ought to be able to get these through any good tool dealer in your own neighbourhood. If not, Melhuish, in Fetter Lane, E.C., is able to supply them.—D. D.

**Covers—Insects in Wood.**—H. G. B. (*London, N.E.*).—Yes, covers for binding Vol. I. of WORK have been prepared, and are obtainable for 1s. 3d. each. Get them through your bookseller or newsagent. Your second question is more difficult to answer, for you don't say what sort of insects are in your desk. Are they in the wood, or do they simply make your desk and papers a dwelling-place? If they are in the wood, it is not easy to get rid of them—almost impossible, in fact. The only thing you can do is to wash benzoline into the holes. Other kinds of insects can generally be got rid of by cleanliness and care, as you are no doubt aware. Growl away, if it does you any good. You are not the only one who is given that way. I daresay you will have noticed this, as you are a subscriber from the first.—D. D.

**Varnish.**—E. L. H. (*Liverpool*).—I am afraid the varnish you used must have been of an inferior quality or wrongly used. If you go to Minton's, or any of the other large paint and varnish manufacturers in Liverpool, you will find there is no difficulty whatever in getting a good clear varnish which will dry hard.—D. D.

**Hand Camera.**—X. Y. Z.—We will bear your suggestion in mind. The preparation of working drawings to be of value to our readers is a matter of time and skill, which the gentleman alluded to might not find it convenient to supply. This class of instrument, to be really useful, is little more or less than an ordinary small camera in a cover, to attract little attention as possible during use, the plates being contained in ordinary dark slides, the addition of a finder and means of effecting the exposure being arranged on the outside of the case; the lens also being set to bring everything into focus beyond a certain distance. The variation of form and detail, but embodying the above conditions, is simply illimitable. Of course, high finish of a camera for such a purpose is much less needed than for one for ordinary use. If credence was to be placed on the advertisements, we see every maker has the best, provided with a sufficient number of double dark slides. Drawings and description for making have already been given in the first volume of WORK. A lens and instantaneous shuttle and very little knowledge in carpentry would suffice to make a workable instrument. The more unlike any other the better for detective purposes.—D.

**Spanner.**—E. W. S. (*Eastbourne*).—The spanner is correctly described and fairly drawn in your sketch. It is, I find, stamped "Bauer's Patent," with the No., which is so worn on the spanner I saw that it is unsafe to quote it. I am almost certain I have seen it for sale at a machinist's shop in Church Street, Shoreditch; but I have no doubt that it can be procured by order of any tool-dealer, preferably those serving gas and hot-water fitters. My inquiries have satisfied me that it is a good and useful article.—B. A. B.

**Cycles.**—PURCHASER OF CYCLE.—The machine from which the design Fig. 3 in June 21st issue was made was of Humber & Co.'s make.—P. B. H.

**Fret-working.**—ELGEE.—I do not think that you are infringing any copyright in making the things you describe; but even if the idea has been originated by you, I am afraid you would not find it pay you to register the design. There is nothing sufficiently meritorious about it—in fact, the design is in many respects decidedly weak and meaningless. Try and improve, and when you have produced anything really good, offer the design to one or other of the large fret-pattern publishing firms, such as the one you name.—D. D.

**Dry Walls.**—A. B. (*Renton*) asks if there is a composition to prevent damp from rising. There is not, so far as I know. I think that the house must have been erected without a damp course—that is, a course of pitch and tar well boiled and laid upon the first course of bricks, just above the

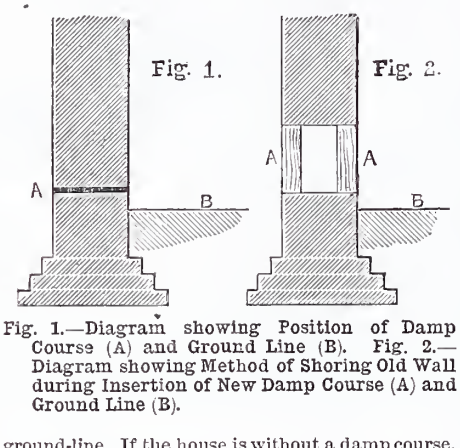

**Fig. 1.—Diagram showing Position of Damp Course (A) and Ground Line (B). Fig. 2.—Diagram showing Method of Shoring Old Wall during Insertion of New Damp Course (A) and Ground Line (B).**

ground-line. If the house is without a damp course, the best method I can recommend you is to knock the plaster off the wall inside, say for a height from 4 ft. to 5 ft., and face the same with the best Portland cement. If the house you mention has a gable end, the best way to make a good job of it will be to cement it from the apex to the ground with good cement; if this be too expensive, cover the gable end entirely with pitch and tar; and lastly, if this does not remedy, the only way will be to remove two or three courses of bricks and insert a damp course. Now the best material for you to use is roofing felt, laid on boiled tar, as per sketch.—W. B.—[After coating the wall with Portland cement, I should face with Keene's cement, especially if the wall is to be papered. I have treated a battened wall in my own house in this manner with the most satisfactory results.—ED.]

**Gum or Resin.**—G. R. R. (*West Calder*).—As you do not say for what purpose the varnish is required I am unable to help you so fully as I should like. It may, however, be said that the manufacture of varnish is not suitable work for amateurs. You will do better by putting yourself in communication with a varnish manufacturer, and telling him just what you want. If you get a colourless varnish, you can easily make it any colour you may want by using a suitable pigment or dye. I should say you will get the colour you wish for with picric acid.—D. D.

**Model Boat Building.**—POGLL.—A paper on the kind of craft you refer to has been ordered from a competent hand.

**Putty.**—Q. R. S. (*Grays*).—Mix a quantity of whiting into a stiff paste with linseed oil, rubbing and heating it well before using. For particular purposes, as for fanlights, iron-framed greenhouses, and other places where the lap or hold is very narrow, a little white lead may be added to advantage. Coloured putty has a mixture of red ochre, lamp-black, or other colour, with the whiting. Soft putty: 10 lbs. of whiting and 1 lb. of white lead, mixed with the necessary quantity of boiled linseed oil, adding to it ½ gill of the best salad oil; the last prevents the white lead from hardening.—Y.

**Writing-desk.**—SECOND HAND.—The initials o the plate of your writing-desk cannot be well erase without removing the plate, unless you are pr pared either to sacrifice appearance or to rub dow the surrounding woodwork to the same level. think you will probably be able to remove th plate without injuring the surrounding wood you heat it. The heat will probably melt, or, a any rate, soften the cement with which the plate i fastened down. If you injure the wood, you wi have no difficulty in concealing defects by the us of stopping. Probably, a new plate would cost s little that it might not be worth while preservin the old one.—D. D.

**Waterproofing Canvas.**—E. H. (*Hampstead*).—To render tents waterproof, they may be coate with boiled linseed oil and terebin, 1 gill of th latter to 2 quarts of oil, two coats being sufficien —Y.

**Saw Sharpening.**—Q. R. S. (*Grays*).—Use triangular file, and sharpen *every other* tooth on on side first, then proceed in the same way on the othe side; after that, use a saw *set*, with which ever other tooth on one side first, and then the othe side, are slightly bent, so as to make the teeth *clea* their way through the wood being cut. In som instances, if the teeth are uneven on the points th file is run along them before commencing to sharpe the teeth, so that they may all be of equal length —L. Y.

**Ship and Naval Craft.**—There are no books o periodicals published that would help you. Yo cannot do better than write for all information a to the classes at the School of Naval Architecture South Kensington Museum, London, S.W.—Y.

**Fire-grate.**—ONE IN A FIX.—A good dea must depend on circumstances, which I am, o course, unacquainted with, as you do not tell m anything about them. I think, however, as you object seems to be to increase draught, that th best way will be to bring in the fresh air below th fire.—D. D.

**Folding Screen.**—INVALID.—To make a screer draught-proof at the folds, use a rule-joint hinge As these are somewhat costly, you may prefer t effect your purpose by simply tacking a piece o cloth, or something similar, over the joint, leaving sufficient fulness to allow the screen to be folded.—D. D.

**Luminous Paint.**—R. E. D. (*Gateshead*).—In answering, to the best of my knowledge, your question—which is of more than individual interest —I may mention that a short notice of this article is given in No. 42 of WORK (Vol. I., page 662). I draw your attention to this, and the name of agent therein given, as I think you will probably find your best and cheapest course to be the direct purchase of the paint. The following particulars of Balmain's luminous paint may not have come to your notice. The basis of Balmain's paint is calcium sulphide, prepared by subjecting calcium sulphate (plaster of Paris), mixed with one-third its weight of charcoal, to a strong heat. Both substances should be previously finely powdered and well mixed together, and a conveniently sized fire-clay crucible is necessary for the heating. To make it into paint, take fifty parts of the prepared calcium sulphide (CaS) and four parts of bichromate of potash, and grind thoroughly together, and then convert into liquid paint form by adding good "outside copal" oil varnish. Another receipt I append: Take thick oyster-shells; clean, and burn them until red-hot. Break them up when cold, and sort out the black-looking and darkest portions. Pound up the remaining shells to a fine powder form, and then place alternate layers of this and flour of sulphur to within an inch or so of the top of crucible, the layers being some half-inch in thickness. Fill to the top of crucible with well-kneaded clay, and let it become hard by gentle heat. Then place the crucible on a fire, and endeavour to get the whole to a dull blood-red; and then try to keep it so, by careful attention, for not less than one hour, and longer, if the clay well seals it up. Set aside to cool gradually, and then reduce its contents to a fine powder. This should result in a bright blue luminous paint. Mix with gelatine and water solution, or gum Senegal solution, if required for indoors, and for outdoors the above *best* varnish; for boiled oil and turpentine will answer in good drying weather, used in about equal parts. If this is required for your gate or railings, have the iron-work well scraped and free from rust, and well coated with a common *oxide* paint before using the luminous compound. White-lead paint would not answer so well; the luminosity stands best on oxide. I hope this may be of some use to you, and point out in what respect your experiments have been wanting.—F. P.

**Whitewashing, etc.**—INQUIRER.—I am surprised that, having taken WORK monthly from the first, you have learned so little of the above subject. No. 50 (Vol. I.) contains a long article on distemper and its practical applications, whitewashing being the lowest or commonest phase of the subject. I will, however, try to assist you, in face of your long and carefully written inquiry. Now, the good, solid-looking jobs cannot be done with common lime; but you must get its *carbonate*, viz., common whiting, for the basis of your mixture. Although lime, freshly slaked, may answer for a time, it will peel off, as you know, after accumulated coats, no matter whether it be called lime, or sold, with a fanciful name, as a "patent distemper." To get a good job of distemper, *all* old lime must be thoroughly scraped off; and when you do this on a few jobs, you will

ish you had never put lime on. If you only take f the loose places—no matter how well you make spread the preper distemper—these patches will nrely be noticeable, being either a different colour, else showing the shade from a different plane or vel of surface. I give you instructions for both new id old jobs. *For new plaster*, if the price will and it, after stopping all cracks, etc., coat with a irly strong mixture of warm size, with a very little hiting in it, just to tint it; then soak the whiting water, putting the former into the latter; pour ff all surface water; well stir with the hand and m, and add the *warm* size: never use it hot unless ecially instructed. If you cannot get and keep atent jellied size, try Cannon's concentrated powder. he *best* glue will answer, however, if prepared us: put to soak in cold water overnight; then, ext day, break up with the hand, and treat it just fficiently to mix the glue and water thoroughly. dding "hotglue" will spoil any distemper; common lue or common "size powders," so-called, will also ake any mixture turn out "stainy." For tinted hitewash ("distemper"), add the stainer or pigent, whether lime blue, Venetian red, or ochre nd umber, to the slaked whiting, and well mix ith the same *before* adding the size. Mix the pigent with a little water first; don't put it into the hiting in a dry form. When made, let it cool efore using; it will then be set, and will want a ood brush, not a thin "rag of a thing," to spread it. *or old work*, if you can't scrape all the dirt and me off, take the loose off, and coat with the size oating, as above. You may then spread the jellied hitewash with comfort, and with less fear of stains. Before re-coating proper distemper work, the old istemper ought always to be washed off; this is nuch easier to do than scraping lime off. Ceilings nay be done once or twice without washing off; ut the results are only "cheap," and often "nasty." Soft soap is quite unnecessary. With pains and atience, combined with practice, you are bound to ucceed.—DECORATOR.

**Lantern Slide Painting.**—E. D. B. (*London, N.*).—Ordinary oil colours, such as are sold in tubes or the use of artists, do for lantern slide painting. Only those that are transparent, such as Antwerp blue, viridian, rose madder, raw sienna, carmine, and yellow lake, must be used, as all you require to do is to stain the surface of the glass. An excess of pigment, or the use of opaque colours, would prevent the light shining through the colours, and giving a reflection on the screen. Mix the colours with amber varnish, and apply with camel-hair brushes, putting the colours on evenly and thinly. The use of the finger to blend and soften the tints s to be recommended; and skilful lantern slide painters do a great deal by dabbing the tints with the broad part of their finger. A soft kid glove also is used on the finger. You had better practise on a piece of glass the laying of skies and flat tints, until you can do it fairly well. Clouds are taken out of a tint of blue with the finger. Photographs on glass, or positives, are largely used now, and colour admirably.—F. M.

**Marble Black.**—S. P. (*Middlesboro'*).—Although the size and shape of the articles would have been useful for me to know, I think you can easily obtain what you require. As, I conclude, you are not afraid of soiling your fingers, I would suggest mixing lamp-black with cold water, and using the black fluid instead of plain water for the plaster castings. Of course, this would only result in a *grey;* but it is a better ground than white to finish upon. You may then give the castings, being quite dry, a couple of coats of French polish or patent knotting. This will stop the suction of the plaster. Three coats may be necessary to do this, and it must be spread quickly and carefully, in order not to roughen the surface or damage the sharpness of the casting. When the suction is thus stopped, you will probably find the black enamel a ready and effective finish. The ordinary "tin enamels" of the quick-drying sort are rather prone to crack, however, so you may desire some other more reliable finish. French polishing with the rubber would be best, if the article was of a nature to be so rubbed; but a small, intricate casting would have to be done with a camel-hair brush. If it were desired, black could be added to the polish, or you could coat the casting with *ebony* water-stain before knotting and polishing. The most permanent finish on *broad* work would be coating with "ivory black" flat paint, next three or four coats of "polishing copal" varnish, and then polished to the real marble gloss with a piece of felt, sweet oil and rotten-stone, or putty-powder. I hope this will be useful.—T. P.

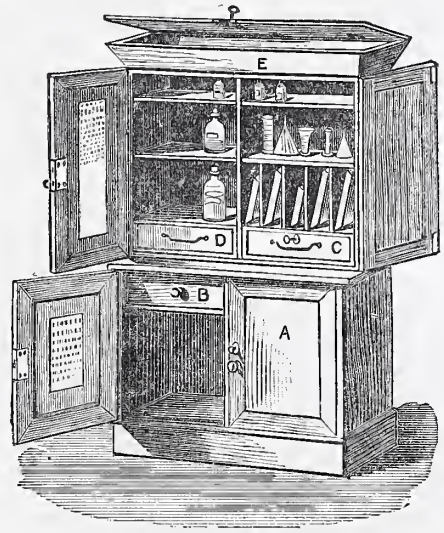
**Fret Machine.**—F. C. (*Belfast*).—I can see very plainly where you are wrong, and I will do my best to help you; but at the same time I do not like the tone of your letter. In the first place, you say you have made a machine according to my instructions exactly. I say you have not, and that is where you are wrong. For a spring I use indiarubber, that being my instructions given. I find it more suitable, because you can increase or decrease the strain upon the saw at pleasure by putting more on or taking some off. If you follow out the instructions given, the machine will work. The one I use is precisely the same as given, and answers my purpose. You must increase your spring power. Fret saws will stand a very great strain. You say that myself and friends extolled the above machine to the skies. Yes, and will still continue to do so, for we know its value.—J. D. W.

**Zither.**—H. L. (*Carlisle*).—You ought to be able to obtain what you require at almost any good musical instrument shop; but if you still wish for my assistance in the matter, I should be very happy to give it and help you to get what you want. The cost of an instrument suitable for your requirements would be about two guineas, and tutors may be had from 2s. 6d. upwards. The Editor has my address, which I have no doubt he will let you have if you send a stamped addressed envelope.—R. F.

**Dulcimer Wood.**—C. B. A. (*Streatham*).—A complete set of wood for an F dulcimer, as described in "The Dulcimer: How to Build One," Vol. I. of WORK, would be about 7s., or, including bridges, sound-hole rings, feet, and stand, about 10s. 6d. The thicknesses given are for rough stuff, except where otherwise stated. It would be a decided improvement if you used all yellow pine for back braces, etc., on account of its greater sonorosity, the only drawback being its greater cost. The joint in the back runs from side to side, but if you used pine you could get it wide enough to dispense with this joint, which would be a further advantage. Send to Chilvers & Co., St. Stephen's, Norwich, for their price list of fittings, etc.—R. F.

**Dulcimer.**—CAWD-HUD.—If you refer to WORK, Nos. 31, 38, and 41, you will find full information concerning dulcimers.

**Photographic Cabinet.**—E. W. N. (*Cheltenham*).—The following is a design for a useful cabinet or chest, the dimensions must of course be suited for the size of the bottles, dishes, etc., it is to contain: the advantage of the cabinet over the box form is that it is not necessary to remove one article to get at another. The top is made with a



**Photographer's Cabinet—A, Camera Cupboard; B, Cloths and Brush; C, Poisons; D, Scales; E, Paper.**

lid, and forms a useful receptacle for sensitised and other papers: the extreme height need not be more than 5½ ft. In a drawer labelled "poisons" may be kept the more dangerous or valuable chemicals, such as cyanide or gold chloride. One side of the lower part is devoted to cameras and dark slides; on each door is affixed a list of the contents of each special cupboard, which can be added to or altered according to circumstances. The whole forms a compact receptacle for everything required by an ordinary amateur, who takes a pride in his belongings; and as to the size, it may be made to suit the size of the apparatus used, and has the advantage of showing the contents at a glance. In fitting a cupboard of this kind, bottles of different capacities and uniform in shape should be obtained, with a few spare bottles.—D.

**Films from Negatives.**—TED.—The best method to remove the films from their present support is to place the broken negative in a dish, face upwards, containing weak hydrofluoric acid. In a short time the film will easily separate from the glass, and must be carefully removed to another dish, considerably larger than the film, of clean water: another piece of thoroughly clean glass being introduced beneath the film, which can then be adjusted on to the glass, and the two gradually lifted out of the water edgeways together. This must be done slowly and carefully: the water will then run out from between the surfaces, and all that remains to do is to place them on a rack to dry. See that the film is placed on the glass right side outwards, or the negative will print reversed, which would be unsuitable for anything besides carbon printing or transparency making. Blisters occur on papers with a highly glazed surface when they are newly albuminised. Too much difference in temperatures of the fixing and washing baths, and too strong solutions of hyposulphite of soda, will cause them. Prints on paper disposed to this fault should be taken out of the printing frames and immersed for a few minutes in good methylated spirit *before* being moistened with water, or any other solution it may be intended to use. After this spirit-bath the other processes may go on as usual.—D.

**Varnish.**—E. W. N. (*Cheltenham*).—A very good varnish may be made by diluting the best white hard spirit varnish obtainable at the oil and colour shops with good methylated spirit to a proper thinness, or 6 oz. of orange shellac and ½ oz. of sandarach (roughly powdered) mixed with as much silver sand placed in a half gallon bottle and filled up to the shoulder with best methylated spirit. Let this stand in a warm room for a week, shaking it well up daily; then let it stand to settle, and pour off the clear portion and filter through blotting-paper. This makes a very hard serviceable varnish, not tacky or liable to scratch.—D.

**Staining Fishing-rods.**—ANGLER.—A useful brown stain for these is given in the issue of Sept. 26th, No. 132, p. 439, under heading of "Means, Modes, and Methods." Another plan is to mix vandyke brown into a paste with liquid ammonia, and thin down with water till the required shade is obtained. As you appear to have no experience in French polishing, the next best thing to do is to apply the French polish with a camel-hair brush—a polish made by dissolving 3 oz. of best orange shellac in half a pint of methylated spirit will suit. If, however, a brighter finish is required, make and use a varnish as advised in "Shop"—"Varnish for Walking Sticks" (No. 131, p. 429, Sept. 19th issue).—LIFEBOAT.

**Boat Propeller.**—T. B. W. (*Bradford*).—Respecting the model of your pleasure-boat, there seems very little merit in the idea you have suggested for propelling the same. In the first place, the method you have adopted for fastening your apparatus to the boat's keel would obviously impede the boat's progress through the water, which would be a serious objection in the case of either a lifeboat or pleasure-boat, speed being more or less essential with both. Then again, one of the pleasures of boating consists in two or more "oars" being jointly engaged. Your arrangement admits of one person only, besides which, the length of your propellers is such that only one set could be fitted to any boat, as they would catch each other. Generally your idea is most impracticable, and you would be only wasting time to attempt to carry it out, to say nothing on the score of expense.—C.

**Printing Patterns for Crewel Work.**—J. H. (*Stockport*).—The patterns on paper for transferring to the material by use of a hot iron are printed in white wax with which a suitable pigment has been ground up. I am not aware that in printing patterns direct on the material, any particular process is resorted to.—S. W.

**Circular Frames.**—T. H. T. (*Blyth*).—Apply to any wholsale dealer in picture frames or mouldings. Perhaps you might meet with a turner in your own neighbourhood who could make them.—D. D.

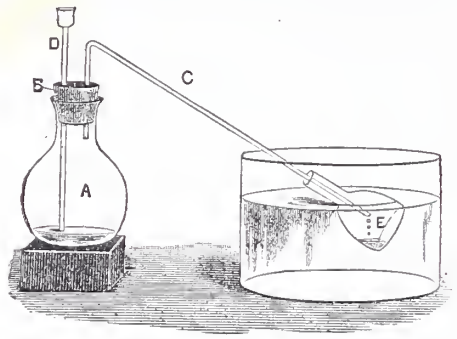
**Carpentering.**—J. T. G. (*Norwich*).—As you have only just begun taking WORK, your best plan will be to get all the previously published parts and read the numerous articles on cabinet making, joinery, and carpentering which have appeared. There is no one article nor series of articles which gives all the rudiments of woodwork, as a moment's consideration must show you; this would be impossible. A very large proportion of WORK is taken up with articles on working in wood, and there is scarcely a number from which you could not learn much. By the way, it is hardly so much information on what is generally regarded as carpentering or joinery as on cabinet making that you want.—D. D.

**Turning Designs.**—T. D. (*Liverpool*).—I do not know of any good turning designs being published. There were some mentioned in our "Guide to Good Things" (WORK, Vol. II., p. 90) which I should think would be much better than the wretched design you enclosed. The address for those I recommend is: F. G. Walker, 21, St. Helen's Street, Ipswich, and the price is 1s. 7d. Any effort to design your own patterns is of benefit, and to buy a turned article, and copy or modify it, is better than buying a drawing.—B. A. B.

**Specifications.**—DOUBTFUL.—A provisional specification is required by the law to contain the title of the invention, and to point out the nature of the invention, fairly, no doubt, but in its rough state, until the inventor can perfect its details, which has to be done in the complete specification, and everything made perfectly clear, so that at the expiration of the exclusive right the public may be able to use or practise it with the same facility the inventor has done. Under the new Act of 1883, the provisional specification is only published with the complete, and if the complete is never filed, the provisional is never published. From our correspondent's remark that he has recently *filed* a provisional, we should judge that he is doing the work himself, in which he has evidently had no experience, or he would know that a provisional specification is *lodged*, and that a complete one is *filed*. If our correspondent has a plan, machine, or system, that is *novel* and *useful*, he will scarcely, in our opinion, succeed in creating a legal property of it by his own unaided exertions, and if it is likely to prove of value, he will find it a very ill-judged course for him to pursue. If he will refer to No. 44 of WORK, Vol. I., p. 694, he will there find information on the subject of patents, of which most

inventors and the public in general are entirely ignorant, but which, if carefully studied, should be of great use to him. Without our seeing the provisional, and knowing what the sweeping alterations he mentions are, we are not in the position to give him any useful advice under the circumstances named. The particulars referred to as being found in No. 44, Vol. I., are too long to reproduce here, and if our correspondent has the first volume he can readily refer to it.—C. E.

**Bromine.**—PROBYN.—Free bromine can easily be obtained from ammonium bromide or cadmium bromide by mixing them with the black oxide of manganese, and distilling with sulphuric acid. 2½ parts by weight of ammonium, or cadmium bromide, are well mixed with 1 part of manganese dioxide and the mixture placed in a flask (A), which should be provided with a well-fitting cork, or caoutchouc stopper (B), through which the end of a bent tube (C) projects a little way, and through which there also passes a funnel-head tube (D), which reaches nearly to the bottom of the flask. 2½ parts of sulphuric acid are now poured down the



**Apparatus for making Bromine—A, Flask; B, Cork or Caoutchouc Stopper; C, Delivery Tube; D, Acid Safety Tube; E, Condensing Flask.**

funnel tube into the flask, which is then very gently warmed. Free bromine is liberated, passes down the delivery tube (C), and should be collected as a dark reddish-brown liquid in a flask or bottle (E), surrounded by the coldest water procurable. See that the cork in the flask fits well, for bromine has a very strong odour, and its vapour is suffocating and very irritating, and also see that the tube (D) dips below the acid in the flask.—F. B. C.

**Table Alteration.**—W. C. (*Hurst, Berks*).—Not knowing exactly what your round table is like, or what the pedestal is, I cannot advise you else than to leave it as it is, or make a dining-table with semi-circular ends, supplying a rectangular piece which I should fix to the pedestal, supporting the semi-circular ends on slides, and a leg, or two legs, to each. The extension possible would not be great, say about equal to a circumscribed square to the circle of present table, or perhaps a little more. Considerable ingenuity would be required to make a successful job, but I see no other use for an old loo table if altered.—B. A. B.

**Damaged Waterproof.**—W. G. C. (*Sierra Leone*).—Under the circumstances stated there is no remedy but cutting out the entire part that is damaged, and all that part to which the liquid has reached where at present no damage is apparent. Then get a piece of the same kind of waterproof, and let it be 1 in. larger all round than the space included in that of the removed portion. Having trimmed the opening neatly to a round, square, or other suitable form, stretch the sheet evenly on the floor with the proofed surface under, and with some rubber solution paint the edge of the opening all round with a width of 1 in. Over this lay the part to be inserted, and when it is placed in its proper position press it down over the joining with a heavy flat iron, and iron it down all round so as to get all the air out and bring the parts into close contact. If properly done, it will, when dry, be found a good job, and the sheet as good as ever, except that the double thickness at the edges of the patch will show what has been done. There is no means known by which the surface can be renewed or restored to its pristine state.—C. E.

**Hydraulic Propulsion.**—C. Y. H. (*Smethwick*).—When our correspondent has brought his "idea" into a *practical* form, either in a *model* or in a set of *drawings*, showing its practicability, he will *then* have something tangible to deal with; otherwise, the "idea" is of no benefit to anyone, and cannot in that state be treated or dealt with. The steering by means of the propelling power is not by any means new. We travelled on the Thames nearly forty years ago in a boat propelled by a jet of water, and by inclining the jet to the right or left the boat was made to answer the helm. Years before this a screw propeller was arranged so as to be turned right or left, and thus steer the boat or vessel, and we think it was patented, but the complication and wear and tear seem to have acted prejudicially to its introduction, and we believe it was never developed further than being fitted in a small launch. Our correspondent will only be wasting his time in trying to get anyone to join the "idea." When he has provided the means of demonstrating the correctness of his "idea," and brought what is at present imaginary into the condition of being an actuality, he will then have some basis to work on which he has not at present, and cannot have whilst he cannot show that the "idea" is practicable.—C. E.

**Iron Safety Bicycle Frame.**—W. W. (*Manchester*).—A safety frame built of iron pipes is generally much heavier than that with steel tubes. Iron pipe is only put into the cheapest machines, which are so roughly finished that the tubes show lines all along and a furrow where the tube has been joined in making. By moving the hand round the tube a lumpiness will be felt which is entirely absent in weldless steel tube.—A. S. P.

**Rocking Cradle.**—FATHER.—I cannot undertake to teach you how to rock a child's cradle in WORK, or devise any method "whereby a cradle would rock itself when started for from ten to fifteen minutes." You will find a reply in "Shop," in No. 50, relative to a wooden swing cradle; another in No. 161, on a child's cot that does not rock, and another on a child's rocking boat in No. 102. There is also a fourth in No. 122 on a swing bassinette.

**Incubator.**—G. R.—I am glad to say that the promised paper on the Atmospheric Incubator has reached my hands, and will appear as soon as possible—that is to say, in December, which is the earliest possible time that arrangements already made for the appearance of articles in hand will permit.

**Monogram.**—W. K. G.—I am sorry to disappoint you, but the demands on "Shop" space are far too great to allow me to give any more monograms for the present, at all events.

## III.—QUESTIONS SUBMITTED TO CORRESPONDENTS.

**Bending Metals.**—J. C. (*Scarboro'*) writes:—"Would any readers give me information as to the best method of bending steel or brass beading (⅛ in.) for fenders, ashpans, etc.?"

**French Medal Glue.**—ESOR writes:—"Can any of your readers inform me as to the best method of preparing French medal glue for use on wood, and for keeping a quantity always ready for use where about 28 lbs. are consumed per day? Does glue, by being kept boiling hour after hour, lose any of its intrinsic qualities?"

**Re-transfer Ink.**—LITHO writes:—"Would any reader of WORK tell me the way to make re-transfer ink from plate to stone?"

## IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Wicker Stains.**—F. H. (*London, S.W.*) writes, in reply to A. B. (*Westminster, S.W.*) (see page 462, No. 133):—"You should wash the wicker chair quickly with strong soda water, and then rinse it off with plenty of clean water, under a tap if possible, then stand it in the sun to dry. When quite dry stain the worn parts with burnt umber, or if red, with burnt sienna (ground in water) and a little stale porter. When this is dry, varnish the whole of the chair with brown hard varnish, and it will look as good as new. The varnishing must be done quickly; do not go over it twice, or attempt to smooth it, as it were, but when once on, let it remain until quite dry."

**Black Varnish.**—M. (*Bishop Auckland*) writes, in reply to CARADOC (see page 446, No. 132):—"One of the cheapest varnishes for iron is tar varnish. It is made by boiling gas tar and asphalte, and well stirring till melted; then take it from the fire, and mix with mineral naphtha. The boiling and mixing must be very carefully done, as it is very liable to take fire. A piece of wet sacking is generally kept in readiness for such an emergency, when it is put over the mouth of the pan. As the price is low, I should advise purchasing it ready made, rather than run any risk."

**Pumps.**—M. (*Bishop Auckland*) writes, in reply to J. H. (*No Address*) (see page 398, No. 129):—"You will find sections and descriptions of engines, pumps, etc., in 'The Model Engineer's Handybook,' by P. N. Hasluck."

**Bath Heat.**—M. (*Bishop Auckland*) writes, in reply to ROUND O (see page 414, No. 130):—"If you write to Mr. T. Fletcher, of Warrington, he will supply you with a gas-heater to heat the water as it runs into the bath."

**Indiarubber Mat.**—M. (*Bishop Auckland*) writes, in reply to ROUND O (see page 414, No. 130):—"You might try the cement used for fixing the tires on bicycle wheels."

## V.—LETTERS RECEIVED.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—H. E. P. (*Plaistow*); R. L. T. (*Plumstead*); D. G. C. (*Bradford*); A. W. B. (*Bristol*); J. G. (*Hull*); H. S. (*Ponder's End*); H. B. S. (*Liverpool*); J. M. M. (*Bristol*); J. E. B. (*Chesterton*); H. T. M. (*Acton*); G. P. (*Elgin*); J. P. A. (*Walthamstow*); WOODWORKER; WATER ASPIRATOR; J. R. (*New Brompton*); SEA GULL; E. R. D. (*Sherborne*); H. A. H. (*Ryde*); C. E. T. (*Liverpool*); AIR PUMP; E. E. S. (*Newton Abbot*); G. M. L. (*Selborne*); A. E. T. (*Bury*); R. W. C. (*Douglas*); CARVER; G. P. (*Elgin*); C. A. P. (*Finsbury*); R. G. H. (*Birmingham*); J. A. (*Gristhorpe*); J. P. (*Hastings*); T. B. B. ## STAGE CARPENTRY.

BY WILLIAM CORBOULD.

PROFILE — BOARDS FOR PROFILE — COVERING BOARDS WITH CANVAS — PREPARATION OF GLUE—GLUING AND PRESSING BOARDS—SET PIECES—MAKING WINGS AND SET PIECES—PUTTING PROFILE ON WING.

IN this series of papers I shall deal with the making of profiles, set pieces, practical doors and windows, vampires, etc., borders, rollers wings, etc.

*Profile.*—I shall commence first with the making of profile, and I may here say that to do this properly you will require no little attention to the instructions here laid down, because if badly done it will entail a deal of after trouble; on the other hand, if well done you can cut it and work it to anything.

Some of my readers, no doubt, will not know what profile is, and what it is used for. Profile is a thin board with canvas well glued down to it on both sides. When this is dry and hard you can cut it with a knife or profile saw into any form: such as the edges of wings in which you wish to represent foliage, rocks, etc., when a straight-edge would be out of place; but if a piece of profile is put on to the straight-edge of the wing, you can put it to the painting. This, however, will be carefully explained hereafter.

*Boards for Profile.*—The boards required for this purpose are usually about 10-cut — that is, a 1 in. deal would cut down boards about 1 in. thick, and either 9 in. or 11 in. wide. The canvas required for the purpose must be pretty open—that is, rather coarse in the web. Many use paper-hangers' canvas, but canvas not quite so coarse may be used, or even common unbleached calico will do. Let your glue be the best you can get—that is to say, get Scotch glue, and always use it. Now for the preparation.

*Covering Boards with Canvas.*—We will suppose that we have three boards to do—they may be 9 in. or 11 in. wide. You must cut your canvas a little less than the width of your boards, so as to allow of stretching when rubbing down; the canvas must not come beyond the edge of the board when finished, because it must be part and parcel of the board itself when cutting it up as may be required.

*Preparation of Glue.*—The best way to prepare the glue is to have a small pail and break up the glue into it; place this in a large pail, put water into both, place them on the fire, and let them boil until all the glue is dissolved. The glue should be of the same consistency as castor-oil.

*Gluing and Pressing Boards.*—Lay the board on a bench or table, and take a large brush and well cover the board with glue about 4 ft. at a time; lay the canvas on, well stretching it, rubbing from the centre towards the edges; go on gluing and placing the canvas on the same way until you have covered the board. Now take a piece of canvas or rag, soak it in the water, and squeeze it out, but do not leave the rag too dry; commence at the end, and rub until you bring the glue through the canvas—that is, until it assumes the appearance of soap. When you have finished, turn the board over, and go through the same process on this side as on the other. When you have finished, you must get a number of pieces of wood, about 1 ft. long and 1½ in. thick. Lay these pieces on the floor in a dry place, and where you will not want to disturb them for four or five days at least. Place the pieces about 18 in. apart, lay the board that you have just finished flat on these pieces, and having done this, go on with another board. When finished, place some more pieces of wood on the board you first laid down, placing the second board on the slips previously laid on the top of the first one. Go on doing this until all the boards are finished. On the top of

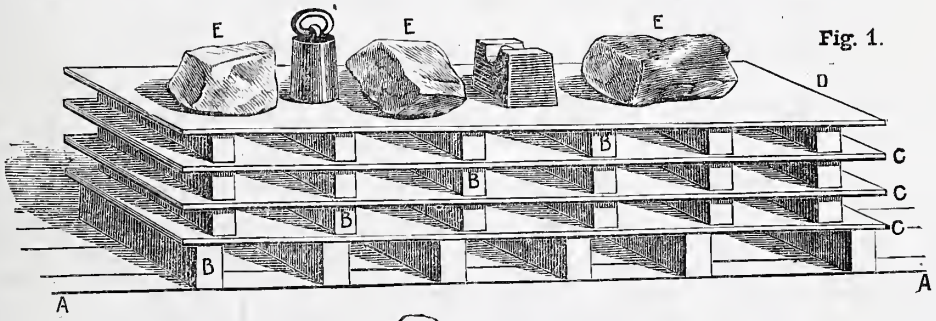

Fig. 1.

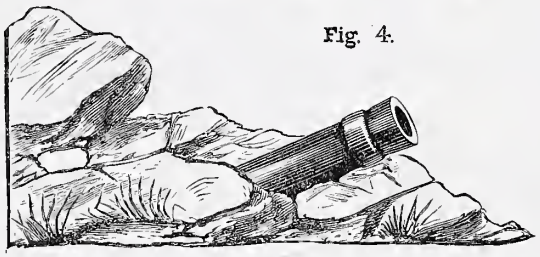

Fig. 4.

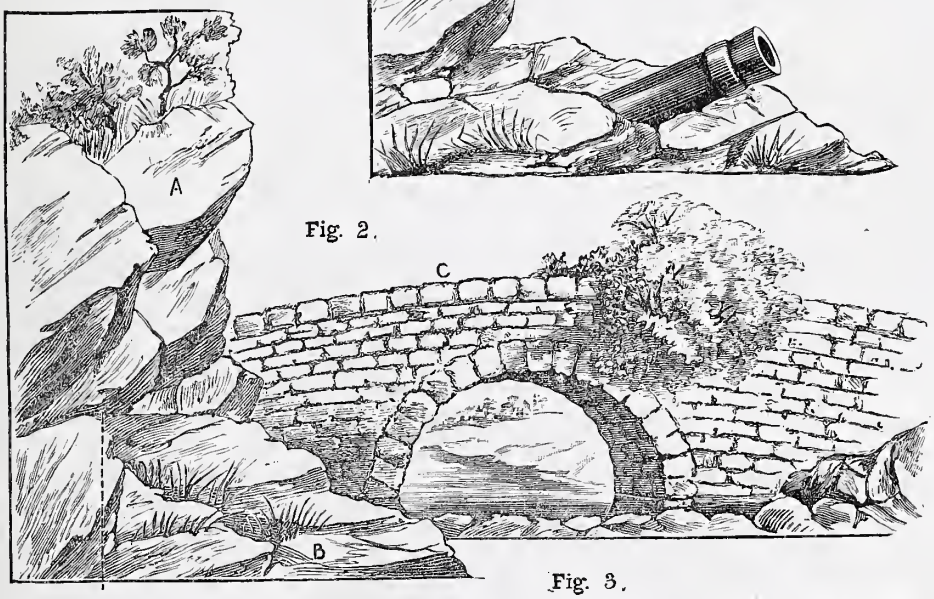

Fig. 2.

Fig. 3.

Fig. 1.—Boards glued and covered with Canvas, piled to allow them to dry. Fig. 2.—Wing (A) and Two Set Pieces (B, C) in Combination. Figs. 3, 4.—Set Pieces.

the last board place some slips of wood as before, and on the slips lay either one board or some pieces of board, as you may happen to have about the workshop. On these pieces of board place some heavy weights—anything will do, whether iron weights or stones. In four or five days the whole will be dry and fit for use. You will see by this method that the air can freely circulate through the whole pile, as shown in Fig. 1. In this, A A is the floor; B, B, the blocks of wood placed between the boards; C, C, C, the three profile boards; and D is the board placed on the top of the profile boards, whereon are the weights, E. As I said before, anything will do if heavy.

*Set Pieces.*—Set pieces, such as rocks, banks, or foliage pieces, are sometimes set partly on the stage from one of the wings, and at other times right across the stage, as shown in Figs. 2, 3, and 4. In Fig. 2 the wing is seen at A, the set piece at B, and the bridge, C, is also a set piece, placed a little back from the wing, leaving an opening between for entrance or exit. The bridge piece, being set also a little in front of the scene, gives the stage a very picturesque appearance; but more of this hereafter, when we come to borders.

*Making Wings and Set Pieces.*—We now come to the making of these wings and set pieces; 3 in. battens are generally used for the framework, or floor boards, which run about 6 in. wide when ripped down through the middle, answer the same purpose well enough. Let us take a wing first. Supposing it to be 12 ft. high and 3 ft. wide: you would cut two 12 ft. lengths and three 3 ft. lengths; the proper way to put them together would be by mortise and tenon, as in Fig. 5; on the other hand, if it should be that the "scenic artist" or stage carpenter is an amateur, and does not happen to have the proper tools, he may put the framework together by halving, as shown in Fig. 6. By using good glue and wire nails, say 1¼ in. long, so that they will turn and clench, the wings will be quite as strong as if they were mortised and tenoned.

*Putting Profile on Wing.*—The following is another way:—Butt the parts together, cut a piece of profile neatly, and glue and nail this on as shown in Fig. 7, in which A is the piece of profile with the edges bevelled off; B is the corner when finished. Fig 8 shows how the profile is put on. We will suppose O P to be the side of a wing; it will be seen that a rabbet is cut at A so that the edge of the profile board may be laid in it when ready. Well glue the rabbet before laying in the profile, and then fasten it all along with small flat-headed nails; of course, the wing or set piece is made first, and in covering them with canvas, never allow the canvas to come too close to the edge of the frame, and keep the tacks quite 1 in. from the edge of the canvas, because after tacking down you must hold up the canvas with one hand while you use the glue-brush with the other. Then take a damp rag and rub it well down; when dry, it will be ready for painting, as in Fig. 13. You must at all times allow sufficient canvas to cover over the edge of the profile after it is nailed on. Do not forget this.

Figs. 9, 10, 11, and 12 are the back views of wings and set pieces, Figs. 2, 3, and 4 showing the way they are put together. Fig. 12 would be hinged together in the centre by hinges known as back-flaps, so that the portions of the painted side shut up face to face. The centre partition must be covered with a strip of canvas to hide it, making the painting appear as one.

## HOW TO SECURE COPYRIGHT IN DESIGNS.

BY CHARLES KELSEY.

INTRODUCTION—DEFINITION OF A DESIGN—SCULPTURE NOT INCLUDED — HISTORY OF THE DESIGNS COPYRIGHT—WHERE DESIGNS ARE REGISTERED—ACT AND RULES, PRICE, AND WHERE OBTAINED—WHO CAN REGISTER—DEFINITION OF "PROPRIETOR"—DESIGNS MUST BE NEW OR ORIGINAL—DEFINITION OF "NEW OR ORIGINAL"—WHAT IS "PUBLICATION"—SUBDIVISION INTO CLASSES—LIST OF CLASSES AND REMARKS THEREON.

*Introduction.*—In past numbers of WORK, several papers dealing with Patent matters have appeared, which have been of great value in explaining the method of procedure necessary to obtain the grant of a Patent, and also in putting before the readers the general principles of the law relating to Patents. But hitherto the section of the law which deals with the protection by Registration of Designs, Patterns, Shapes, and Ornaments — that is, the Designs Section of the Patents, Designs, and Trade Marks Act of 1883—has not been prominently brought before its readers; and I propose, in the following pages, to deal with this subject in a similar manner to that in which Patents have been treated.

A slight reference to this Registration appeared at the latter end of C. C. C.'s paper on Patent matters in Vol. I., page 545; but the subject is of so much value that it deserves treatment in an independent paper.

The information will be found useful and valuable, more especially by those—manufacturers, designers, and artisans—who design or produce novel articles of manufacture, new shapes for articles of utility, or who ornament or decorate such articles in some new manner, or who design the patterns for such purposes. The law applies to all materials, and therefore the information will be useful to workers and designers engaged in all the varied manufacturing industries which are carried on at the present time.

Also, it will be useful to those amateurs who design or produce for pleasure some article, shape, pattern, or design, which, if manufactured and placed on the market through the ordinary channels of trade, would be likely to "hit the public taste," and secure a sale.

The inventor of simple articles may here also find welcome information as to this alternative method of securing protection to that involved in "taking out a Patent," which is open in some cases by proceeding under this section of the Act; for the protection acquired by Registration is fully as effectual—if the subjects are such as may be rightly included in its scope—while the cost is much less, the procedure in making the application much more simple, and the granting of protection much quicker; thus enabling the inventor to put his goods on the market without delay, which is frequently of great importance to catch some particular market. Frequently these points—the initial cost and the inability to make the application unassisted or to employ a Patent agent—form insurmountable obstacles to the worker who is desirous of obtaining a Patent; but if the subject be such a one that it can be registered as a design, these obstacles will be evaded, for, after perusing the present paper, any person with ordinary intelligence will find no difficulty in making an application unassisted, and the fees are so trifling as to be within the means of almost everyone.

It will be my aim at the same time to give much necessary information as to the rights so acquired, and the general principles of the law.

It is but natural that designers and inventors should be anxious to secure, as a reward for their ingenuity and industry, a fair share of any profits earned by the sale of their inventions and designs; but they frequently fail in doing so from ignorance of the steps to be taken to secure their rights, and my object in writing this paper is to do my best to supply this deficiency.

*Definition of a Design.*—In dealing with this subject, evidently the first step must be to ascertain what is or can be rightly included under this section of the Act; and the step is an important one, because it is worse than useless to attempt to gain protection by provisions which are not applicable to the subject in hand. The term "Design" is a very wide one, and different definitions of it will be found in different dictionaries; but as the term is defined in the Act itself, in Sec. 60, we must turn to that source for our information. The definition is rather a long one, but its importance must be my apology for quoting it *in extenso*. Sec. 60 runs as follows:—"'Design' means any design applicable to any article of manufacture, or to any substance, artificial or natural, or partly artificial and partly natural, whether the design is applicable for the pattern, or for the shape or configuration, or for the ornament thereof, or for any two or more of such purposes, and by whatever means it is applicable, whether by printing, painting, embroidering, weaving, sewing, modelling, casting, embossing, engraving, staining, or any other means whatever, manual, mechanical, or chemical, separate or combined, not being a design for a sculpture or other thing within the protection of the Sculpture Copyright Act of the year 1814 (54 George III., Cap. 56)."

First, it will be noted that the field covered is very wide. We may take it for granted that designs in any material will be included, no matter how executed.

It should be noted, also, that the words "for the pattern, or for the shape or configuration, or for the ornament thereof," are the essential words of the section, on which everything turns; and anything which is included under these terms may be rightly registered under this section.

Under the terms "for the pattern" and "for the ornament" are included all designs or patterns used for the decoration or ornamentation of surfaces or articles, and thus the works of pattern designers for all materials, such as calico printing, paper staining, house decorating, lace weaving, leather embossing, etc. etc., are included; as also are the works of the decorative artists and workers who are engaged in ornamenting articles of beauty or utility—such as china decorators, wood carvers, marquetry workers, metal chasers and engravers, jewellers, bookbinders, etc. etc.

Under the terms "for the shape or configuration" are included the external or internal shapes or forms of all the various articles of manufacture—such as the shapes of the potter, wood-worker, glass-blower, metal-worker, stone-carver, ornamental modeller, etc. etc.

It will be noted that "sculpture" is specially excluded from this section, as its protection is dealt with by the Act before referred to. As, doubtless, amongst the

readers of Work are sculptors, modellers, and plaster-cast makers, I propose dealing with it in a supplementary paper, for a brief *résumé* of this Act would be welcomed by them.

It is the terms "for the shape or configuration" which render this section useful for the protection of many minor inventions. If the essential novelty in an invention consists in making the article, or portion of the article, of some novel shape or configuration—perhaps to enable it to better perform its purpose, or, it may be, to ensure greater facility in its manufacture, or for some other such reason—it will be possible to secure protection for it by Registration as effectually as by patenting it. But if the invention does not conform to these terms, it is useless to register it under this section, for if a certificate was granted by the Office, a plea that it was not such a one as should have been registered would, if upheld by the Courts, invalidate the Registration.

The history of this part of the Act throws a good deal of light upon what may and what may not be protected under the Designs Copyright, and so I give a brief *résumé* of it.

*History of the Designs Copyright.*—The first attempt of the legislature to grant a Copyright in Designs was the Act 27 of George III., Cap. 38, which came into operation on June 1st, 1787. This was intended to protect the patterns printed upon linens, calicoes, cottons, and muslins. It gave a protection for two months only from the date of publication. The designs were not registered, but the proprietor's name had to be printed upon each piece. The Act was enacted for one year only. In the following year a continuing Act was passed. By subsequent Acts the period of copyright was extended, and designs printed upon other textile fabrics were included.

The next great step was in 1842, when a further Act was passed, 5-6 Vic. Cap. 100, known as the "Ornamental Designs Act," which instituted the present practice of registering a design to secure copyright, and the protection was extended to patterns and ornaments applied to the articles produced in other trades. The shapes or configurations of articles of manufacture were also covered, the object being to protect, in like manner, the shapes produced by the potter, metal-worker, and other manufacturers.

In 1843 was passed the "Useful Designs Act," 6-7 Vic. Cap. 65, the object of which was to protect articles of utility which were not designs for the ornamentation of articles, or ornamental shapes of articles, such as were included in the "Ornamental" Act previously alluded to. The protection granted, to quote from the Act, applied "to any new or original Design for any article of Manufacture having reference to some Purpose of Utility, so far as such Design shall be for the Shape or Configuration of such Article, and that whether it be for the whole of such Shape or Configuration, or only for a part thereof."

This Act was, in fact, used for the protection of the many minor articles which were being invented, which were not considered by their owners sufficiently important or sufficiently valuable to be made the subjects for application for the grant of a "Patent." At that time the Patent fees were much higher, and the procedure very complicated.

These laws remained in force up to 1883, when the present Act was passed, which extended the term of Copyright to a uniform period for all designs, lessened the fees, and brought both useful and ornamental designs under one head.

Under the old arrangement it was very difficult to draw the line between a useful shape and an ornamental shape, so the distinction was abolished. Now any article of manufacture in which the shape or configuration of the whole or of some part is the essential

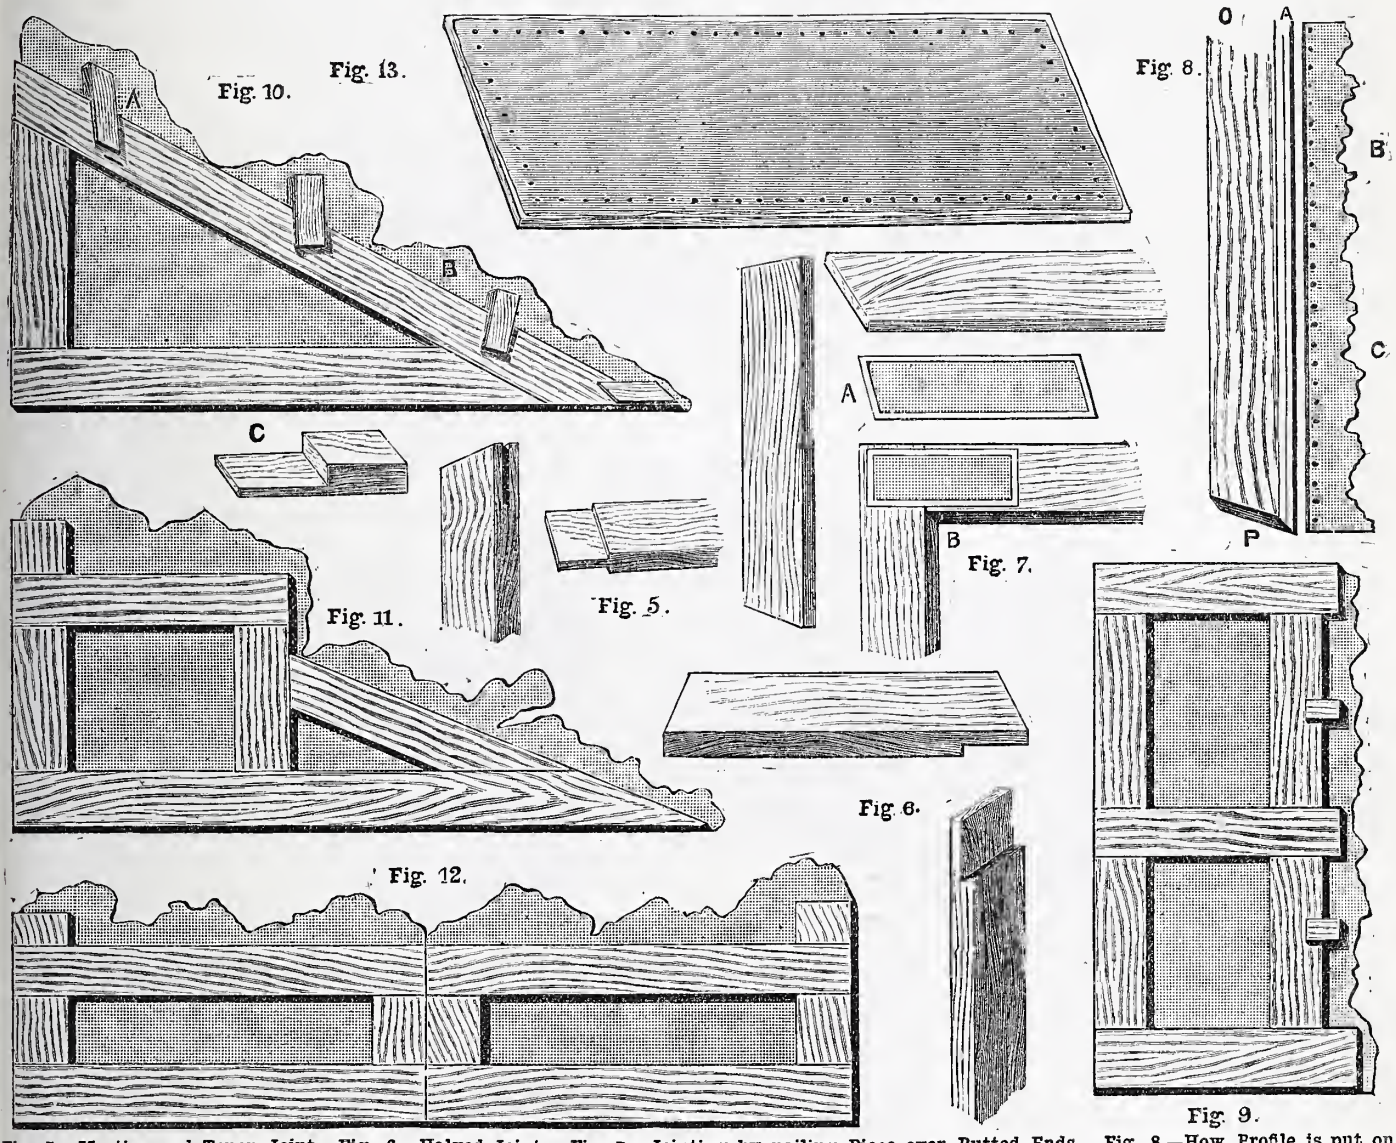

**Fig. 5.—Mortise and Tenon Joint. Fig. 6.—Halved Joint. Fig. 7.—Jointing by nailing Piece over Butted Ends. Fig. 8.—How Profile is put on. Figs. 9, 10, 11, 12.—Back Views of Wing and Set Pieces in Figs. 2, 3, 4. Fig. 13.—Covering Profiles with Canvas.**

novelty may be registered, whether it is for some purpose of utility or for ornament merely, in addition to designs, patterns, and ornaments formerly included under the "Ornamental Designs Act." It is this inclusion of the old "Useful Designs Act" in the present Act which renders it applicable for the protection of many minor inventions for articles of utility, and if they conform to the conditions stated, such articles may be thus fully protected.

*Where Designs are Registered.*—As will have been gathered from my foregoing remarks, this forms part of the business carried on at the Patent Office, situated at 25, Southampton Buildings, Chancery Lane, London, W.C., which is under the direction of the Comptroller-General and his staff, who act under the powers conferred upon them by the Act of 1883 and the rules made in connection therewith, the terms of which control and regulate all their actions.

*Acts and Rules, Price, and where Obtained.*—Copies of this Act, commonly called the "Patents, Designs, and Trade Marks Act, 1883" (price 1s. 7½d., by post 1s. 9d.), may be procured at the Sale branch of the Patent Office, 38, Cursitor Street, Chancery Lane, London, E.C., or will be forwarded to any address if Postal or Post-Office Orders are sent addressed to the Comptroller.

Copies of the Designs Rules, 1890, are 6d., by post 6½d. Copies of the amending Act of 1888 are 1½d., by post 2d.

Copies of "Instructions to Persons who wish to Register Designs," which contain much valuable information, are given gratis at the Office, or will be forwarded by post if applied for.

*Who can Register.*—The person entitled to copyright is the proprietor of the design, and the Act gives a definition of "proprietor" in Sec. 61. It runs: "The author of any new or original Design shall be considered the proprietor thereof, unless he executed the work on behalf of another person for a good or valuable consideration, in which case such person shall be considered the proprietor; and every person acquiring, for a good or valuable consideration, a new and original Design, or the right to apply the same to any such article or substance as aforesaid, either exclusively of any other person or otherwise, and also every person on whom the property in such Design or such right to the application thereof shall devolve, shall be considered the proprietor of the Design in the respect in which the same may have been so acquired, and to that extent, but not otherwise."

In this respect the Designs section differs from the Patent. The grant of a Patent to a person who has seen some invention abroad and first brings the knowledge to this country is valid, but the definition of proprietor seems to preclude such a proceeding in the case of a design. Here the applicant must be either the author, *i.e.*, the original inventor, or designer, or a person who has acquired the right from such original inventor for a "good or valuable consideration," such as works executed while the designer or inventor was in his service, or by purchasing the design from the original designer. In the case of purchasing a design, it will be well to have a formal document to that effect, to prevent difficulties arising on that point in the future. In one decided case it was held that the grant of a sole agency in this country was not such "good or valuable consideration" as the law meant; and so it would seem that the design must be acquired by cash or its equivalent. Persons who have stolen or copied a design without giving the original designer or inventor some consideration for it, will not be protected, even if a certificate be granted to them.

*Designs must be New or Original.*—All designs applied for should be "new or original," and such as have not been, prior to the date of application, "published" within the United Kingdom. These are important points to be borne in mind, for neglect of them will invalidate the registration. They are the most usual pleas raised as a defence to an action for infringement of copyright, and have given rise to many interesting decisions from the judges who have tried these actions. As these decisions govern the construction, or the meaning of the words used in the Act, they are useful in deciding what the Act deems "new or original," and what is meant by "publication." In one case it was held that the reproduction of an article which had been published in a different material—such as making a design in metal which was well known in china—did not constitute a "new or original" design; and in another case it was held that the copying of a photograph of a well-known person upon china was also not a new design; but it has been held that a new combination of old parts was perfectly valid. The law is, evidently, only for the protection of the design or invention which has been *bonâ-fide* invented or designed by the applicant or by some person working for him, and which they have registered before publishing.

It has also been held that designs must be "substantially new or original" to claim protection. Some slight variation is not sufficient: there must be, in each case, a substantial novelty.

*What is Publication.*—On the question of publication, it will invalidate the Registration if the design has been exhibited, before Registration, for the purpose of seeing if orders could be obtained for the article, although, in the same case, it was held that consulting an expert as to the workability of the design was not such "publication" as would be fatal to the after-acquired rights.

It should be understood that, even if a certificate of Registration has been acquired, if these points of publication and novelty have not been attended to, the Registration will be invalid.

*Subdivision into Classes.*—The Act and Rules subdivide designs, for the purposes of Registration, into fourteen classes, taking as the distinguishing feature the material in which the design is to be produced.

Registration only applies to the class or classes of goods for which application is made. Thus a design may be registered as a paper-hanging, and may be produced by another person as a cretonne or furniture print; so that it is necessary, if the applicant wishes to apply his design to more than one class of goods, that he should make separate applications for each class required. Only by taking this precaution can he prevent his design being used by other workers in different materials. In cases of doubt, where the applicant cannot decide for himself the proper class in which his application should be made, the Comptroller is empowered to decide for him by Sec. 47-5, and this is much the best course to adopt under such conditions, for this reason: placing in the wrong class by the applicant would most probably invalidate the Registration, but if placed in the class which the Comptroller directed, such a plea could not be raised, as he is specially empowered to decide such a point.

*List of the Classes, with Remarks thereon.*

The classes are:—

*Class I.*—"Articles composed wholly or chiefly of metal not included in Class II."

This includes, in addition to designs executed in all the ordinary metals, works in the precious metals, other than jewellery.

*Class II.*—"Jewellery."

This term, "jewellery," is treated by the Office as meaning personal ornaments. This class is not restricted to articles in metal, but includes designs produced in the other substances used in jewellery, such as precious stones, jet, coral, horn, etc.

*Class III.*—"Articles composed wholly or chiefly of wood, bone, ivory, papier-mâché, or other solid substances not included in other classes."

This is a general class for designs for works executed in solid substances other than those included in the special classes. It includes, in addition to the materials mentioned, designs for works in stone, and such substances as indiarubber, gutta-percha, vulcanite, etc.

*Class IV.*—"Articles composed wholly or chiefly of glass, earthenware, or porcelain, bricks, tiles, or cement."

Primarily for designs in fictile materials which are solidified by baking or burning, like pottery, bricks, and tiles, and also for glass. The term "cement" includes designs in artificial stone—possibly articles made in plaster of Paris—and such-like articles which are formed in a plastic state, and solidify afterwards without the aid of heat.

*Class V.*—"Articles composed wholly or chiefly of paper (except hangings)."

Includes, besides paper, designs on or articles made with cardboard and the like substances, and it becomes sometimes difficult to draw the line between these and the papier-mâché included in Class III. This class also includes designs for Christmas cards, greeting cards, etc., but such goods are much more frequently entered for Copyright at Stationers' Hall, and on this point it is difficult to say which is the more correct proceeding; but when they are of some novel shape in addition to the ornamentation of their surface, Registration as designs would appear to be the safest course. Frequently manufacturers register them at both Offices, and possibly they would be entitled to some protection under the law regulating Artistic Copyright.

*Class VI.*—"Articles composed wholly or chiefly of leather, including bookbinding of all materials."

This class includes designs for all leather-covered goods, such as writing and despatch and dressing-cases and the like, which are so covered. Also designs for bookbinding in all the materials which are used for this work.

*Class VII.*—"Paper-hangings."

The class includes designs for all the varieties of paper-hangings.

*Class VIII.*—"Carpets and rugs in all materials, floorcloths, and oilcloths."

This includes designs for practically all floor coverings with, perhaps, the exception of indiarubber matting, which is put with the other indiarubber goods in Class III. Also all varieties of oilcloths.

*Class IX.*—"Lace, hosiery."

Includes all kinds of lace goods, and such hosiery goods as stockings, socks, and the like, and knitted piece goods.

*Class X.*—"Millinery and wearing apparel, including boots and shoes."

May be said to be restricted to designs for complete articles of wearing apparel. Designs for portions of articles of wearing

apparel sold separately—not as complete, made-up articles—are placed in the class indicated by the material of which they are composed.

*Class XI.*—"Ornamental needlework on muslin or other textile fabrics."

Includes all designs for hand and machine-wrought embroidery or ornamental needlework.

*Class XII.*—"Goods not included in other classes."

This, as appears, is the class for designs for miscellaneous goods which are not included in any of the other classes. Designs for textile narrow goods—such as fringes, frillings, braids, gimps, ribbons, tapes, and the like—are included in this class.

*Class XIII.*—"Printed or woven designs on textile piece goods."

This is a very large class, including designs for all textile piece goods—that is, goods sold by the yard—including all the varieties of dress goods and furniture textiles. Includes, in addition to printed and woven designs, patterns executed by stamping or embossing and cutting, like varieties of velvets and velveteens.

*Class XIV.*—"Printed or woven designs on handkerchiefs and shawls."

In addition to the articles indicated, includes textile squares generally—such as bed-quilts, table-linens, towels, and such-like goods as are sold complete in themselves, singly or by the dozen.

It should be noted that in the wording of the first six classes—with the exception of Class II.—the words "wholly or chiefly" occur. This means that articles composed of more than one material should be applied for in the class of the predominating material. Previous to 1890 the words were "wholly or partly," and this necessitated registration in each of the classes over which the materials of the design ran, so that the amendment made is all in favour of the applicant.

It should also be borne in mind that it is the design or patterns applied to some material, or the forms or shapes executed in some material, that is protected—not the material itself.

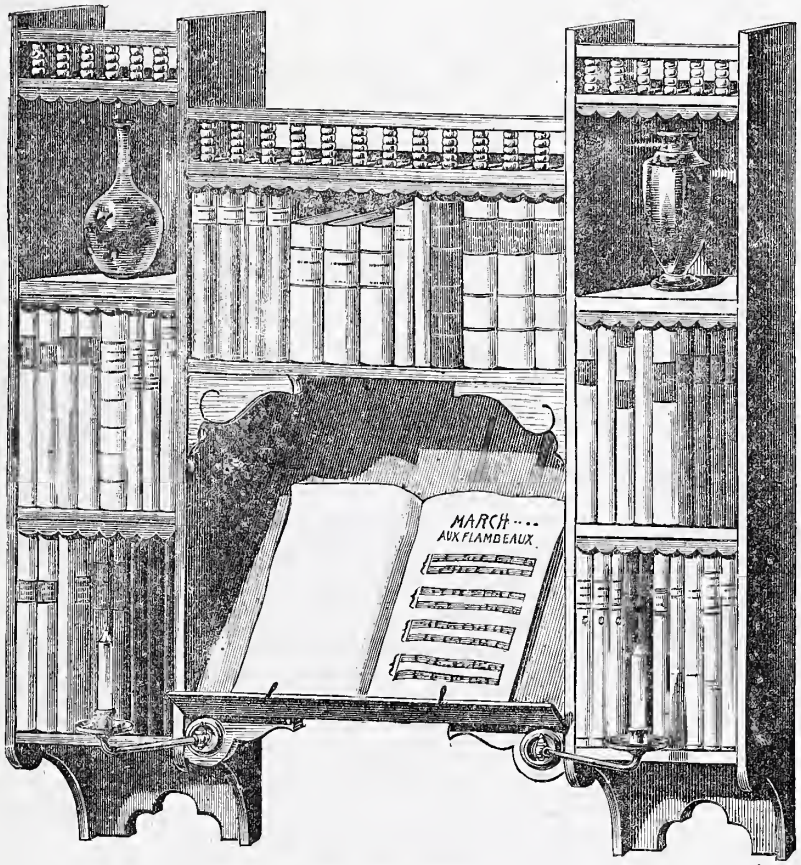
Having now fairly launched the reader into the subject, I shall, in the subsequent papers, deal with making the application, and the procedure the Office takes thereon; and then deal with what constitutes an infringement, and various other minor matters relating to the subject. I shall deal with every branch as completely and succinctly as space will allow, and I shall make no apology for doing so on account of the interest which is evinced in everything relating to patents and patent laws and usages as soon as the subject is broached in the pages of this Magazine. That it is one that is of the highest importance to every workman cannot be denied, and on this ground alone it deserves consideration in WORK.

## FITMENT TO HANG ABOVE A SMALL HARMONIUM.

BY PALGRAVE MORRISON.

"AND underneath her window He used to go and strum, In mode at which you would have wept, His dull harmonium." So sang Mr. Gilbert in an early "Bab Ballad," and the painful truth of his words will be echoed by all those who live next door to a plodding amateur who has begun to blow the reed-chest. Mr. Spurgeon was once asked if a man could play the trombone in a brass band and yet remain a Christian, to which he is reported to have replied: "That no doubt he might, yet, if he practised at home, his next door neighbour could not."

But in spite of well-deserved sarcasm freely launched at the people who make the most distressing noises with the aid of the harmonium, it is capable of excellent music; and if only I dared to give a column of advice—from one who knows—I fancy it might be more useful to the amateur than the music-desk and shelves it is my object to describe.



Fitment to hang above a Small Harmonium.

If one who has suffered the miserable incompetence of a so-called music-desk to carry out its professed intention could say here plainly what he really thought of that irritating imposture, either the Editor would cut it out, or the Magazine itself would be disgraced by profanity. For the arrangements made by the manufacturers of small harmoniums to keep the music at the proper angle and allow its pages to be turned over are, as a rule, merely absent—for the small harmonium never suggests that anyone might occasionally be tired of playing from memory, and wish to have his music in front of him.

Then, again, like a piano, the instrument, as a rule, has no convenient receptacle for printed music. To obviate these two omissions, and afford, beside conventional, artificial light, is the not very subtle problem attempted herein.

As a piece of joinery, it is enough to rouse the disdain of the ultra-professional workers who cannot tolerate simplicity; for it is but a set of shelves after all, and to seriously consider the readiest way to make such a thing is beyond hypothesis. The decorations are confined to a few small spindles—*à la* the anachronistic "Early English Queen Anne"—but these may be replaced by fretwork, or still better, by carving, if desired.

The practical point is that a good, useful music-desk is offered; that space for two candle brackets to be affixed is also given. The shelves will be useful for books if the amateur's musical library is limited. With regard to size, the desk should, I know, be 24 in. wide, and the whole structure not less than 3 ft. 4 in., the average width of the instrument. Supposing it to be built of 1 in. stuff, that would allow the side recesses to be only 6 in. each, whereas they are shown twice as wide. But I prefer the whole to overlap the instrument; if personal reasons decide otherwise, there is no reason why there should be any side shelves on the music-desk level. All the details are purposely left vague to suit the taste of any who wish to adapt an idea, for, after all, the idea is the main thing. If it be an idea, however badly treated, the clever worker soon discovers the way to better it; and so far as I know, obvious though such a thing be, no one has illustrated such a combination of desk and shelving as that suggested in this fitment. The article does not take long to make, and forms a useful present for a friend and a taking piece of furniture for bazaars, which will form a counter attraction to the too numerous cushions and antimacassars which usually form the staple article for sale at these entertainments.

## ASHPAN MAKING.

BY R. ALEXANDER.

THIS short paper is to be taken as a reply to a query on the subject by J. W. (*York*).

The first thing to learn in making these articles is to know how to go and measure for them. I speak from experience, and no doubt many brother workmen can confirm the statement that not one person in twenty bringing an order for an ashpan to an ironmonger has a sufficiently intelligible order or sketch to enable the workman to make it without going to the range or grate and taking his own particulars. To do this, make a sketch of the bottom of the pan like Fig. 1; next measure the width of the fire-hole that it is to fit in; and here it is that an error often creeps in. Bricklayers or

range-setters are only human after all, and frequently the back part of the fire-hole is narrower than the front, so that an ashpan made the right size, apparently, when tried in jams half-way, necessitating either an alteration of the pan or a cutting of the brickwork underneath. To avoid this, cut a small piece of stick to the size of the front, and with that test the back of the fire-hole both at the bottom and top. Whatever the size is, write that at the back of your sketch as shown in example—7½ in. The next dimension to take is the "depth." Do not confound this term with the height, of which I will speak presently; the depth, A A, is the distance from front to back. Always mark on the diagram ¼ in. less than your measure, as a little space at the back does not matter, but it looks very bad to see an ashpan stand out from the grate. We will say for an example of depth 6½ in., and mark it on the plan as shown. The shoulder of the ashpan is generally about an inch each side. Draw a line from shoulder to shoulder and then mark the distance the front has to be from that; it varies from 4 in. to 7 in.,

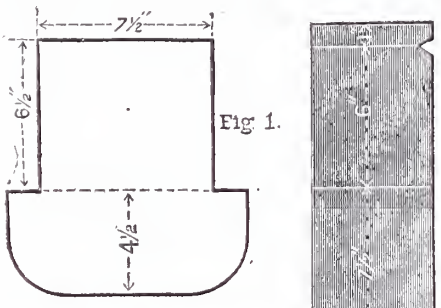


Fig. 1.

Fig. 3.

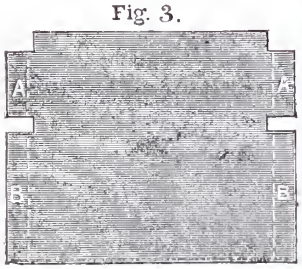

Fig. 2.

**Fig. 1.—Plan of Ashpan for Kitchen Range. Fig. 2.—Flat Pattern of Back Part. Fig. 3.—Flat Pattern of Front.**

according to the size of the ashpan. In our example I have marked it 4½ in. Two more dimensions now need to be marked down—that is, the height of the back part and the height of the front. These, of course, vary with circumstances. I have marked: back 7 in., front 10 in., which is about an ordinary average. Some people cut a paper pattern, but this is unnecessary if the directions I have given are followed, though in the case of a register grate ashpan it is generally necessary. I can only give very brief directions for working up, and must presume, as you are an improver, that you know something of the trade and names of tools and technical terms. Use 24 gauge charcoal iron or soft steel for small size, and 22 ditto for larger ones. First cut out the piece for the back, marking it out like Fig. 2, which is supposed to be for the size given above. Fold the top and wire, leaving the wire out 3 in. at each end; bend square on the hatchet stake down the lines, then bend on the lines; you will find that you must mark them on the other side. Next bend the wire that you leave out straight up. Having got this part of the ashpan true and square, bend a strip of tin or zinc to get the length to cut the front. Cut the piece, and cut a notch each end at the part that is to be the top; at the height of the wire of the back part cut a piece out of the front as shown in Fig. 3; wire the top, and bend round to shape. The parts marked A are bent round and closed over the wire left out of the back, and the parts B are riveted to the 1 in. parts thrown off the back (see A, B, Fig. 1). Next throw off the edge for the bottom, shape up again, and mark out the bottom with a slate pencil, allowing nearly ¼ in. all round; turn up, pane down, and knock up in the usual way. Punch a hole in the centre of front, and rivet in a bright range knob with two or three thick washers inside. If any further information is required, I shall be pleased to give it to any who may ask for it.

## SADDLES FOR RIDING ON HORSEBACK.

### WITH RECENT IMPROVEMENTS IN STIRRUP HANGING.

BY JOHN CHARLES KING.

Several patents are taken out in England in each ensuing year for saddle improvements: for cross and side saddles, some of them to obviate or nullify the very parts which had at some previous time been patented as improvements. And some without the patents are correct as far as they go.

The hunting season is here, and its sure fatalities and lamings of riders follow with increased intensity every year. Seven deaths and six hundred falls, with injuries, were last year's hunting season's record.

A Queen's huntsman boasted ten falls in one run. Thirty riders tilted out of the saddle in view at one fence. All this is discreditable for a nation of horsemen, and should be rectified.

The fault, in the judgment of some experienced riders, is that the stirrup is hung so forward that it does not serve to support the body of the rider at his centre of gravity, but about six inches in front of it, where the feet fail to support the body, unless the body is leant forward over the stirrup fixings. This action of the rider decentralises him, and causes him to tilt forward over the forelegs of the horse, and to use his reins and hands on the horse's withers to effect a balance at the landing from a leap. This weight thrown on to the forelegs of a horse causes him to knuckle-over, or pitch on his knees, unless he pitches the rider over his head and breaks his neck, and thereby saves his own. For it is noticed that if the horse unseats his rider he saves himself often, but if the rider hangs on to the horse, both come down together, sometimes the man undermost.

As all correct riding is by knee-grip, it is obvious that the supplementary aid of stirrups should not interfere with this grip, which in all riders would be the same—at the middle of the horse's body from hip to shoulder, and at the middle line from back to belly. This part of a horse moves but little up or down or radially in turning, hence the graceful pose of the barebacked rider.

The legs need support, and the slighter the better, but it must not interfere with knee-grip, and need not.

The horsemen of the pampas of South America have a hole in the skin strapped on their horses, or a strap pendant from the girth for the leg support, with a hole in it for the toe. If a stirrup is used by them, it is still in the same position, though the stirrup is a block of wood with a hole in it mostly. These men are rarely ever unseated from the wildest horses in flight over rough ground.

So far, all horsemen agree that the stirrup hanging should be more central on the saddle. Why is it not? requires a view of a tree to convey an answer.

Modern trees are made in a way to prevent a central hanging, as will be seen from Fig. 1, of a saddle-tree with its stirrup-bar, which is fixed partly to the pommel point and partly to the belly of the tree, or that part which joins the pommel in front to the cantle behind. This is just three inches too forward at the least, and is the main cause of the mischief that results to both horse and rider.

Why fix it here? begets the question—Why make trees which render any other fixing impossible? Tree-makers know nothing about horses or riders; they make by the gross, and that is all they know or care about. The saddler buys these trees, and assumes they are right, and covers them.

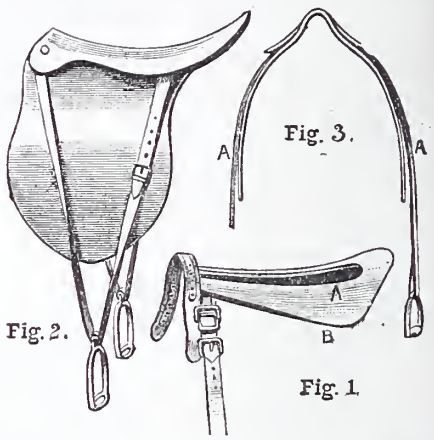

**Fig. 1.—Ordinary Saddle-tree with Forward Stirrup Leather. Fig. 2.—Double Suspension Stirrup Leather Fixing. Fig. 3.—Front View of Saddle, showing where Stirrup Leathers come under the Rider's Knee-grip at A, A.**

The rider buys the saddle, the groom mostly has an interest in approving of it, and the new thing starts on its break-neck career.

"Four men have been killed from that saddle," remarked an old helper in a stable. "Where's the fault?" was asked of him, and answered—"The bars are so forward, that the riders who lean on the stirrup get tipped out before they know it. The old style was to hang stirrup leathers on the bar of the tree three or four inches back, then a man was safer. Military saddles are made so."

However hung, the stirrup leather is right in the way of knee-grip, and forms a shifting wad of leather that prevents fair and easy gripping, as at A, Fig. 3.

The diagram given in Fig. 3 gives a sectional view of a saddle and stirrup from the front. A, A, are the three thicknesses of leather under the knee on each side, being one inch total thickness, to spread the legs wider and mar the perfect grip of the knees, often causing eczema inside the knees with old riders.

The purpose to be gained is of a twofold character in centralising the position of the stirrup and removing the leather from the knee. This has been accomplished in the simplest way possible by a rider who, as

soon as he thought of it, altered his hunting saddle, he being a workman as well as horseman.

The result was a saddle with the stirrup leathers parted so as to hang from two latches, one on the cantle point, the other on the pommel point, as is shown in Fig. 3, so that the grip of the knees comes between the two straps, and the knees are spread an inch less; an essential consideration for safe and comfortable riding, as has been satisfactorily proved by its use by one rider in 10,000 miles' riding in seven years, on young horses, without once having an accident to horses or rider.

## SHORT LESSONS IN WOOD-WORKING FOR AMATEURS.

BY B. A. BAXTER.

### The Plane.

In our first lesson we tried to understand the plane, how to take it apart, sharpen, and put it together. We will now proceed a step, and try to learn to use it.

The learner must not work on a bench that is too high. When the board to be planed is in position, and the worker takes the jack-plane in hand ready to begin, a line drawn through his elbow and wrist should be rather lower than higher at the wrist, though if the fore-arm is level it will do.

Be sure not to attempt to take off thick shavings at the outset, and do not be disappointed—as so many are—if you cannot at once take a shaving off from end to end. If the wood has any hollow in it, it will be impossible to do so, and even if perfectly straight, very improbable that a beginner can do so. Amateurs at the beginning always plane too much off the end near the bench stop, and are too apt to move the arm in the arc of a circle. These errors must be avoided by careful attention. There is no royal road to efficiency in anything.

Try to plane the centre of your material rather than the margin, for if you have a good plane in good order, it is impossible to make the wood much too hollow or concave; whereas, however good the plane, careless use of it can and will make the work convex in every direction.

I know of no better lesson than to try and "face up"—that is, level—two pieces of stuff so that they will, when brought together, be in mutual contact. You will fail several times, but unless you persevere until successful, you need not try to make a piece of furniture or attempt anything difficult.

Just a word on the wood. If you try to plane too small a piece of wood, you will not make such good progress; the little pieces are sure to be made convex in length by a beginner. If experience may give advice, I would say take a piece not less than 2 ft. long—it may be more, in fact. The best results have been obtained by a class of boys under my superintendence by using pieces of wood 4 ft. long, 4½ in. wide, and 3 in. thick. The wood was best spruce, and being too stiff to bend, and affording a good surface, it was cheap material for practice.

When some facility has been obtained, the blade of a 12 in. square or a straight-edge should be employed, to test the accuracy or want of it.

It must not be forgotten that the edge of the plane-iron is necessarily "rounding," or the corners would dig in. The result is that the work tried across presents the appearance of a series of shallow curved grooves. The plane, therefore, must be so sharpened and used as to make these as little noticeable as possible. This is another reason for advocating finely-set planes.

If the 4½ in. by 3 in. stuff has been adopted for a lesson, it will be possible to take another step—that is, to learn what "winding" means, and how to correct it. Procure two pieces of wood equal in size—say, 12 in long, 1½ in. wide, and 1 in. thick. See that they are parallel. These pieces are to be placed across the work, one at each end; then by viewing both, bringing the eye down to glance from one to the other, it will be seen whether the two are in one plane. If they do not appear to lie in one plane, the surface is "winding," and opposite corners must be reduced till satisfactory.

These two lessons must be worked, as, taking so short a time to read, they might be thought unimportant; but upon complete mastery of the plane depends the success of the worker.

## A USEFUL METAL LATHE.

BY SELF-HELPER.

Receipt of Castings—Lining Out—Scribing-block—Drilling the Headstocks—Simple Drilling Press—Reaming out Poppet Cylinder—Grinding out Ditto—Fixed Headstock—Milling Cutter—An Offer—Preparing Cylinder Mandrel—Centre for Ditto—Cylinder Screw—Hand-wheel—Locking Handle—Fixed Headstock—Cones for Mandrel—Lock Nuts—Pulley—Thrust Bracket—Re-lining of Castings—Fitting Bases of Headstocks.

On the arrival of the castings, the first thing to be done is to look them carefully over, and if there are any lumps or rough parts they should be touched up with a chisel and an old file.

It is scarcely within my province in this present paper to describe all the operations of turning, chipping, and filing; but I hope that either myself or another writer in these pages will, in a future number, fully describe these operations, for the benefit of any who do not understand them.

The castings of the headstocks will then require to be "lined out." This is a very important matter in all engineering work, and would require far more space for its full treatment than I am able to devote to it here.

We will take the poppet, as embodying most detail, and proceed to line it out. The centre of the cylinder at the top is found at each end by means of a compass, and centre-punched lightly. It is scarcely necessary for me to describe a centre-punch, but I may mention that it is a piece of steel, as at Fig. 2, having one end coned down to a point, the angle of the point being, when perfect, 55°, and hardened.

The middle point, B (Fig. 1), across the base of the headstock is also found, and marked very slightly at each end. The casting is now laid on its side on some flat surface, and blocked up until the points A and B (Fig. 3) are exactly the same height. It will be found that the corresponding points at the other end will be nearly the same height also, but if the casting is not straight they may not be. In such a case I would have the two points representing the centres of the cylinder—that is, A, and the corresponding one at the other end—brought to the same level; then I would bring the two points, B, and its fellow at the other end, to such a position that one would be higher and the other lower than A. Now I would draw a line right round the casting, on a level with A, as shown. In these operations an engineer would use a metal surface which had been planed and scraped perfectly true to lay the casting on, and to draw the lines and gauge the heights would employ a scribing-block, one form of which is shown in Fig. 4. The pointer can be moved up and down the pillar, and secured at any point by means of a thumb-screw. It can also be drawn in and out and fastened by another thumb-screw. A flat piece of wood, or the top of the dining-table, would do for us instead of the surface-plate, and the heights could be measured by a compass until regulated, and the line drawn round by means of a parallel strip of wood planed down until just wide enough to reach from the surface of the table to A. The lines on the casting will show up much more distinctly if it is rubbed over with chalk before marking, and they can be made permanent by dotting them over at short intervals with the centre-punch and a light hammer. Measuring from A 4 in. along the line, another deep dot may be placed at ×, and a line scribed and dotted at right angles to the line A ×, which we will denote by C D. By standing the square on the table top this can easily be done. The same should be repeated at the other end. A couple of lines, E F and G H, should also be drawn, seven-eighths of an inch at either side of the centre line, and these continued along the base.

Until now the casting should not have been moved when it was once set. It may now be taken up and stood so that the line A × is vertical, and the line C D at one end and its companion at the other will be horizontal. They should be blocked up to the same level, and lines drawn at each side of the casting connecting them, so that there is a line right round the casting near its base. This will be a guide afterwards for us to chip and file down to.

Taking A for centre, a circle ½ in. in radius may be described and dotted at each end, and the lining-out of the poppet is completed. That for the fixed headstock will be done in exactly the same way, except that the lines E F and G H may be omitted. The operation of lining out may appear unnecessary and tedious to the beginner, but it is of the greatest service in supplying lines to which we will work afterwards.

Drilling next demands our attention, and it is here the amateur will find the greatest difficulty, if he has not a lathe or some suitable drilling machine at hand. I will suppose he has only the pillar press and hand-brace, which are to be found in most country smithies. He will require, for the present, two drills, one to bore three-quarters and the other seven-eighths of an inch hole. The chief difficulty is to enter the drill truly. To do this I would describe a number of concentric holes having A (Fig. 1) for the common centre. I would then start the drill, and if it did not work concentrically with the circles, cut a chip out in the direction I wished it to go with a tool like Fig. 5. This can easily be made of a piece of round steel. It is a sort of gauge, and is used like a cold chisel—in fact, the corner of a cold chisel could be made to act as a substitute. When the drill is driven in a little further, it will be found to move towards the part cut out, and by withdrawing it often enough it can be made to become quite central before the shoulders have entered.

The $\frac{7}{8}$ in. drill is to be put through the poppet cylinder, and the tyro will be pretty tired of drilling before it is done. When it is half through, the poppet should be reversed, and the remainder bored from the other end. For the sake of those who have not even a pillar drill to fall back upon, I give in Fig. 6 a plan which I adopted one time to bore a hole about this size with. A pillar was bolted to the leg of the bench, and a long arm pivoted to it with a strong bolt. Another pillar at the other end prevented the arm from swaying about, and also supported a lever by means of which the drill could be released. A weight attached to the end of the arm supplied the necessary pressure. My drill was made of $\frac{5}{8}$ in. square steel, a foot long, and a flat bar of iron, two feet long, with a square hole in the centre and a handle at each end, served to convey motion to it. Of course, the top of the drill was coned to fit a centre in a piece of iron screwed to the lower surface of the arm. A brace could be used in this affair instead of the handles. I do not recommend this in preference to a better machine; I just mention it to show what can be done, and perhaps it will be a useful hint to some readers who might find the drilling an insurmountable difficulty. If the holes from both ends meet pretty fair in the centre of the cylinder, it will be a great matter; but if they are out to any considerable extent, a round file must be used until there is a through hole without any violent projections. This must now be cleared out to size with a reamer. A capital reamer for the purpose can be made of a worn-out flat file, one inch wide. The teeth must be ground off, and the edges backed off to give a cutting edge, as seen at Fig. 7. The point will enter the hole in the poppet for a considerable distance, and act as a guide, and a couple of semi-circular pieces of wood should be employed to steady the tool. It might be held in the vice vertically, and the poppet revolved, if necessary, with a short lever passed through the space between base and cylinder.

The reamer should be worked right through, and the hole will then be found to be very nearly, if not quite, parallel and smooth. If we want to make a really good job of it, we should grind it out. This is effected by casting a cylinder of lead on a bar of iron, and turning it parallel for six inches, and a tight fit for the hole; then it should get slightly bigger—just a shade—and be parallel for three or four more inches.

The front part of the lead *lap*, as it is called, acts as a guide, and the remainder grinds out the hole as it passes in. This will make a far truer and rounder hole than to have the lap fit through at first, and then to press the cylinder which is being ground as equally as possible all round. The grinding is effected by smearing the lead with emery and oil, which is frequently replenished, and revolving it in the lathe. It is a more rapid operation than would appear at first sight. Of course, I need scarcely say that the smallest amount should be taken off by this means—only enough to true and smooth the hole.

I have thus been careful in describing the drilling and clearing out of the hole in the poppet, because it will be found, I think, the hardest part of the work to the beginner; and if he succeeds in producing a perfectly smooth and parallel hole concentric with the casting, he may hope to construct a very good lathe. No pains should be spared in this or in any other part of the work to go as near as possible to absolute perfection.

I now turn to the fixed headstock, which is to have two $\frac{3}{4}$ in. holes bored, one at each end, concentric with the bosses. These holes must be coned out to take the mandrel. The best way to do this is, I think, with a milling tool, which I represent in Fig. 8. It is a tool made from a piece of cast-steel, turned down to a long, conical point, and having teeth cut in its surface similar to those found in the common rose-bit. A spindle passes through a hole in its centre, and a pin prevents the tool from turning on it. The spindle is fitted to a brace or chuck, and, the tool being revolved slowly and pressed against the work, produces a beautiful coned hole, the exact counterpart of itself.

A loose cone at the other end of the spindle keeps the two holes exactly in the same line, which is a matter of the utmost importance.

The dimensions of a suitable milling arrangement would be as follows: Spindle, five-eighths of an inch in diameter and a foot long; mill, largest diameter one inch, length two inches; a quarter of an inch to be parallel, and the remaining inch and three-quarters tapering from an inch to three-quarters of an inch. The loose cone should fit the spindle nicely, and be of the same taper as the cutting cone. Most beginners would find a great difficulty in making a satisfactory milling tool, and so I am tempted to make an offer which is likely to be useful to many of my readers. It is to lend a mill to anyone of the subscribers to Work who is following my instructions in lathe making, for the purpose of coning out a pair of holes, on condition that he pays postage both ways, and deposits with me the value of the tool, as a guarantee for its safe return and careful use. I am induced to make this offer solely through a desire to help beginners, and can in no way gain anything by it.

When the holes are milled out, it would be well to give them a rub of a lap coned down to the proper angle; but I would avoid emery here, as it is almost impossible to get it out of the metal. The grit that is found in the bottom of a grindstone trough, or pounded whetstone, would be just the thing. I ought to have mentioned that the hole, when coned, should taper from an inch at the biggest part, to thirteen-sixteenths at the smallest, thus decreasing three-sixteenths of an inch in an inch and a quarter full.

We have now the handstocks bored and must prepare the mandrels. These are frequently made of good wrought iron, but I prefer steel, either Bessemer or cast. The poppet mandrel is a plain cylinder six and a half inches long, and an inch and a sixteenth in diameter, the extra sixteenth being for turning up. If it comes from the forge rough it should have centres drilled at each end and a cut taken off the entire surface. The ends should be truly squared also. Then it is to be mounted in a chuck and the end supported with a boring collar. In Fig. 9 I show it in the dead centre lathe as being the simplest. A block of wood is screwed against the pulley, a hole having been made in it to clear the centre. Then the lathe is driven, and a hole turned out carefully with a chisel in the centre of the block of wood. The mandrel is driven into this hole, and if it fits tightly it will be amply sufficient to carry it. The free end is supported by the boring collar, which is a plate having a conical hole that the mandrel will enter, but not pass through. This plate is attached to an angle iron, which is bolted to the lathe bed.

While the mandrel is thus driven into the lathe, an $\frac{11}{16}$ in. drill can be pressed against its end with the back centre, and a hole bored to the depth of about three-quarters of an inch; a smaller drill, one nine-sixteenths of an inch in diameter, can then be substituted and the hole continued for about five inches. The mandrel may then be reversed, and a hole a quarter of an inch drilled at the other end for a distance of an inch and an eighth. This hole must then, with a tool, be coned until it is three-eighths of an inch large at the outer end. This tapering would be done best by means of a slide-rest, and some would declare such assistance necessary; but I have often coned out holes by hand.

Having completed the holes, the centre may be prepared to fit the coned hole. It is of the best cast steel, and turned to fit the hole, and afterwards ground into it. The point is then turned while the mandrel is supported as in Fig. 9. The point of the centre should be coned to an angle of 55°, which is something smaller than that made by a triangular file in a piece of thin iron. It is a good test for the coned hole if the centre will run true after having been turned half round from the position in which it was finished; but even if it is a shade out of truth it would be well to be satisfied, as I question whether the hole could be made quite true without very good tools.

Having proceeded so far, the mandrel may be placed between the lathe centres and the outside turned to fit the cylinder, which has been prepared for it. If the centres of the working lathe are too small for the holes which have been made in the mandrel, these latter may be plugged with pieces of iron turned to fit. The centres on which the plugs were themselves turned should be used when turning the mandrel.

It will not be easy to turn this mandrel perfectly round and parallel. Very light cuts should be taken, and then the last touches given with a fine file, and emery cloth stretched on a piece of board. When the point enters the hole in the poppet, on no account should any more be taken off it, for if it is found to fit the end of the hole and not go in further, the hole cannot be parallel. If, however, care has been taken in the lapping operation, this will not be likely to occur. In really well-made lathes, this mandrel fits most beautifully. I know some in which it will not shake when it is out almost to its furthest extent, and we should aim at this degree of perfection in our work.

In Fig. 10 will be seen the cylinder mandrel fitted with its centre pushing screw and nut. The pushing screw is half an inch in diameter and of the length shown, with a collar in the place indicated. It is very often made with a square thread, sometimes left-handed, but this is a matter of fancy more than anything else.

The ordinary Whitworth thread does very well, and it can be cut with a set of dies, and chased to finish and make it true. The nut is turned to fit the $\frac{3}{4}$ in. hole in the end of the mandrel and secured with a couple of little screws as shown. The disc at the back of the collar is drilled, put on a mandrel between the lathe centres, and turned all over; four holes are drilled and countersunk, by means of which to attach it to the poppet. The hand-wheel is also bored and turned, and a little key or feather put in to secure it to the screw, a nut at the back preventing it from coming off. A small slot must be cut in the mandrel, as is seen

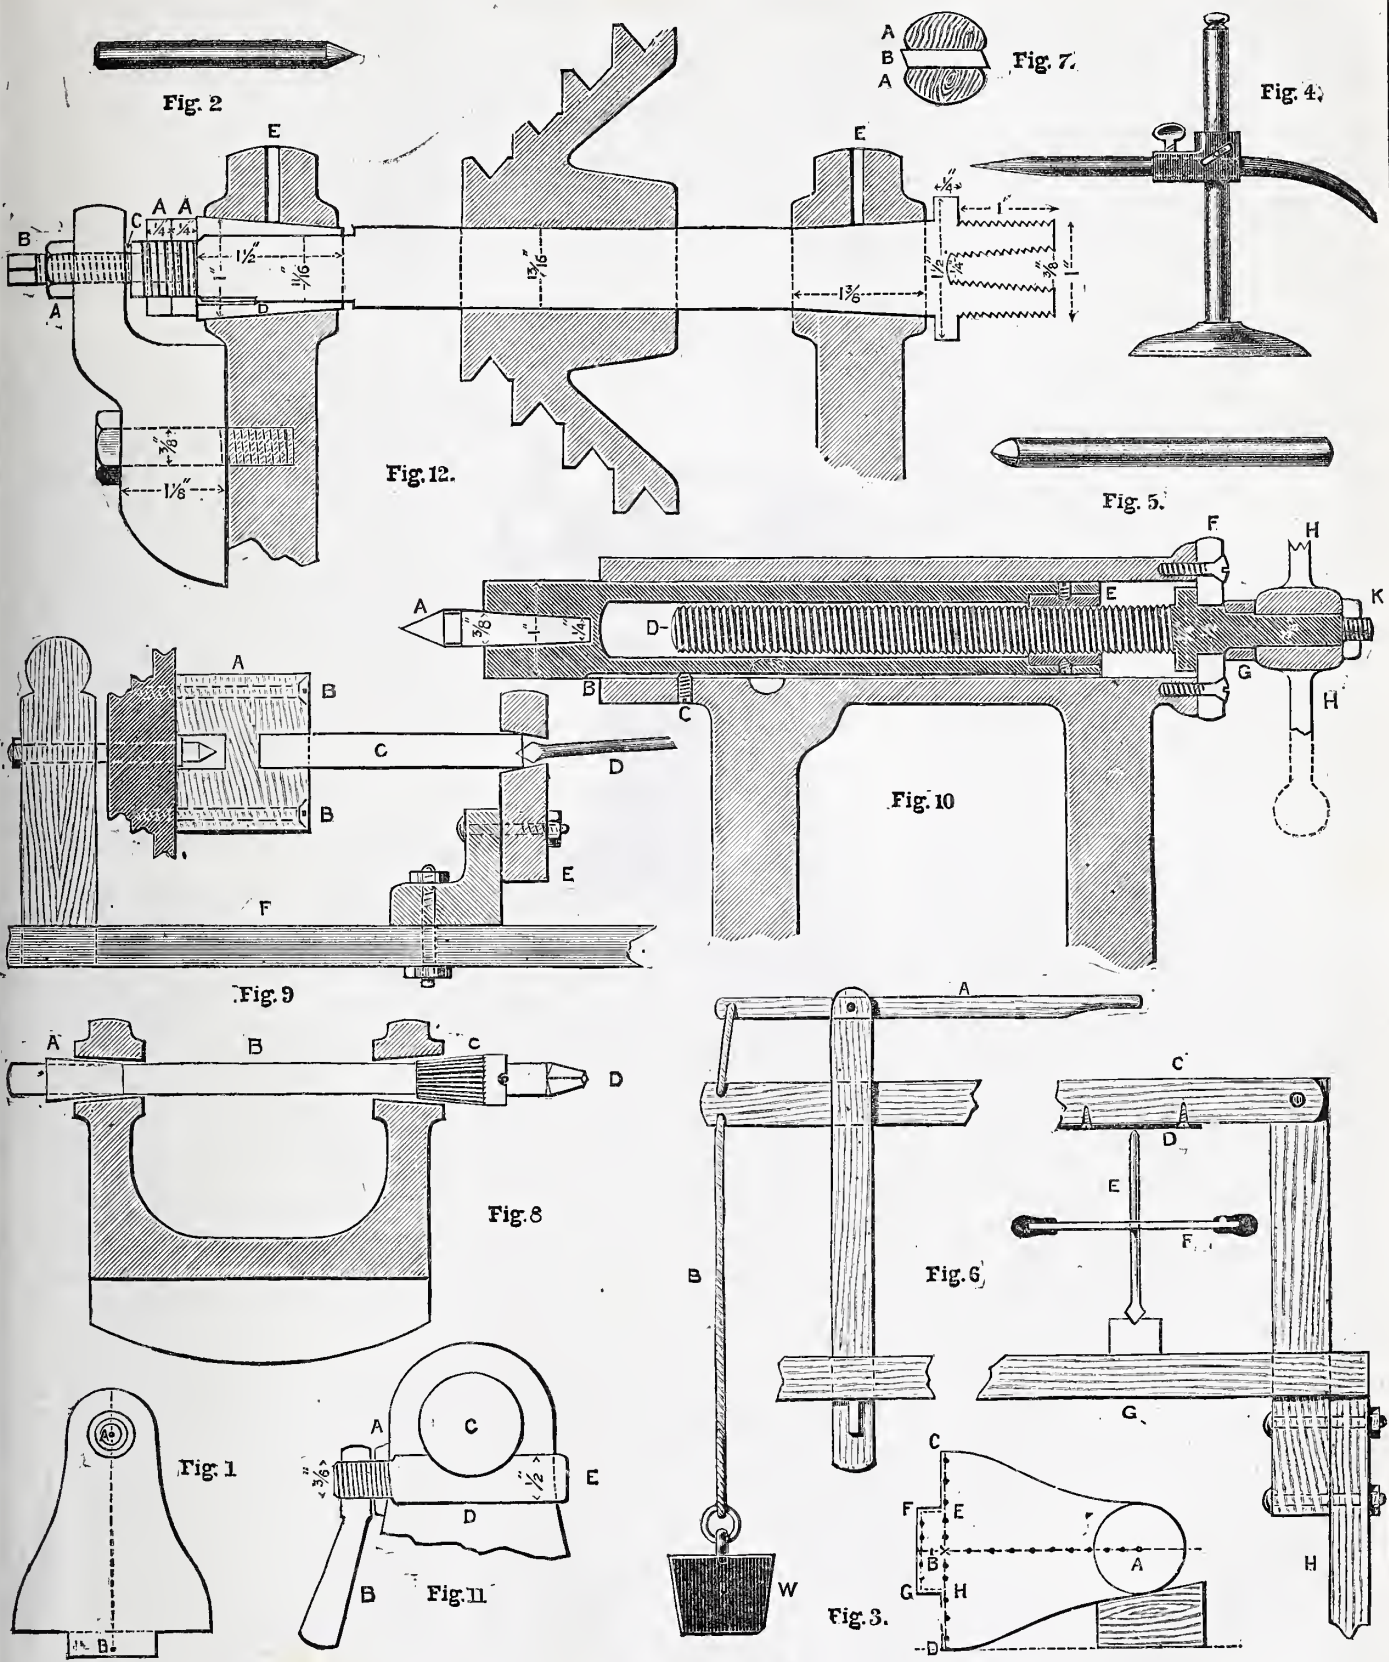

Fig. 1.—End of Poppet—A, Centre of Cylinder; B, Centre of Tenon. Fig. 2.—Centre-punch. Fig. 3.—Poppet laid for Lining out. Fig. 4.—Form of Scribing-block. Fig. 12.—Section through Mandrel (half size)—A, A, A, Lock Nuts; B, Steel Screw; C, Hard Steel Plug; D, Feather; E, Tube for Oiling.

underneath, to engage the point of a screw which is made to project into the cylinder. This slot can be cut out without much difficulty by means of a cold chisel, an eighth of an inch wide, finishing with a small file.

The entire headstock is seen in section in Fig. 10, and Fig. 11 explains the action of the locking handle. A ½ in. hole is bored in the position shown in such a way that it breaks into the cylinder. A piece of steel is then fitted to this hole, and a hollow filed out to the curve of the mandrel; a washer and a handle turned from a piece of half-inch square steel serve to do the locking. It is a very efficient arrangement, and not difficult to make.

Fig. 12 is a sectional view of the fixed headstock, as Fig. 10 is of the poppet. The mandrel should be turned very carefully to the dimensions indicated in the figure. The loose cone at the tail end will require to be very carefully fitted. The hole in it, which is eleven-sixteenths of an inch in diameter, must be very carefully bored and lapped out perfectly round and parallel. It is to fit the mandrel "hand-tight," as some call it—that is, tight enough to be moved by firm pressure of the hand, but neither to shake nor fall off.

Before it has been brought to this state of perfection it should have been roughed down until it was nearly to the finished size; then, when put on its own mandrel and the lock nuts screwed up, it should be carefully finished until it will fit exactly the hole in which it is to run. The fitting of both cones of the mandrel to their bearings will be a tedious piece of work. The holes should be covered thinly with red lead and oil mixed to a thin paint; the mandrel and cone should then be put in place and turned once round by hand. If the cones are marked all over with the red lead they fit perfectly, but if not, the marked parts must be filed or scraped down in the lathe until the desired object is attained. The lock nuts should have a fine thread; gas threads will do very well, but if the work has been done satisfactorily hitherto, it would be worth while to get the mandrel nose and the thread at the back cut in a screw cutting lathe. I have represented the nose as an inch in diameter with Whitworth thread, but it may be made smaller, even as small as three-quarters of an inch. The centre is the same as that for the poppet, and the hole should be coned to the same angle, using the poppet centre to get the correct angle. The pulley is to be bored to fit the mandrel hand-tight, and then turned all over and the V's made. It is secured to the mandrel with a little key, as is also the back loose cone.

The little bracket at the back to take the thrust of the mandrel may be of wrought or cast iron. It is secured with two screws, and another of hard steel, towards the top, bears the end pressure. It works against a little bit of hard steel let into the end of the mandrel.

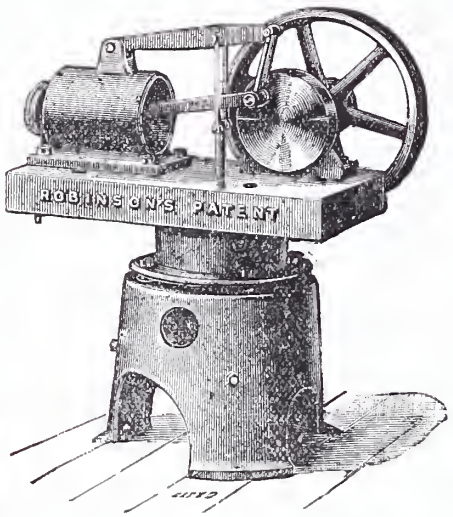
Having the mandrels fitted, the casting should be again lined out most accurately with their centres. If the mandrels occupy the place designed for them in the first lining out, of course the second will correspond with the first: but, if they are a little out, it can be rectified now. The bases of the headstocks are to be planed or chipped and filed to the lines, and the holes for holding down bolts drilled five-eighths of an inch in diameter, and the headstocks are finished. It would improve their appearance a good deal if the end surfaces could be turned smooth and true.

## OUR GUIDE TO GOOD THINGS.

*** Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

### 86.—The Robinson Patent Hot-air Engine.

The Robinson Patent Hot-air Engine, which was invented by Messrs. A. E. & H. Robinson, and is made and supplied by Messrs. Norris and Henty, appears to be one of the most efficient and useful of all engines of this kind that has yet been placed on the market. The inventors and makers claim for it that it is a most useful and



Robinson's Patent Hot-air Engine.

thoroughly good motor for driving small machinery, and is now thoroughly established as a success in the hands of practical users. It is well adapted for amateurs and for professional workmen whose workshops are not on an extensive scale, and do not require an engine of considerable power to drive large machinery. Thirdly, it is absolutely noiseless and without smell. Possessing these essentials, and being in every respect safe and reliable, as a motor it is suitable in any place where small power only is required. Neither eccentrics nor cams enter into its construction, and the only valve to be found in the engine is that which is used to stop it. As there is no boiler, as in a steam engine, the anxiety that will always be felt, more or less, by those who use small engines which, as steam engines, must be provided with boilers, is altogether avoided, as there can be no fear whatever of an explosion. There are many cases in which no other engine could well be used than that which is represented in the accompanying illustration, as it will work for long runs, and therefore for long periods of time, without any attention whatever. There is no exhaust from the cylinder, in which only pure air is used, and this at a moderate temperature, so that very little oil is required. There is no internal combustion or ignition in the cylinder, so that the parts are not subjected to severe shocks, but a steady outward and inward impulse is given to the piston at each revolution of the engine. A minimum of friction and regular working is thus obtained. The cost of working this engine is very low, being only about a farthing per hour where coal or coke is used as fuel. But slight attention to stoking is required, and this can be undertaken by, and entrusted to, a servant or anyone who may happen to be about the place, as no particular skill is required. Gas can be used as fuel, but at a greater cost per hour: and, if gas be adopted, beyond oiling at starting, absolutely no attention is required for hours together. The cost of putting in the engine is very small, there being no special foundation required—in fact, on a reasonably sound floor the simple bolting down to counteract the pull of the belt is all that is necessary. The engine, as above shown, is No. 4 size, and then there are three smaller and two larger. The diameter of the cylinder is 5½ in.; the height, length, and width, taken approximately over all, are 2 ft. 8 in., 2 ft. 3 in., and 2 ft. respectively; its weight is 2½ cwt., and its power is reckoned as being 2-man or ¼-horse. It is fitted with a patent governor, which thoroughly controls the speed. There are no water connections to make with the engine, and there are no complications of mechanism to be found in its construction.

### 87.—"Discovery."

The monthly magazine which is now appearing under this title, and is published by Mr. E. W. Allen, is "devoted to invention, scientific discovery, and the application of science to industrial purposes." There are few readers of WORK, I think, who would not pick up much useful information which could be turned to practical service in the pursuit of any hobby or prosecution of daily employment. Correspondents have frequently asked for a good recipe for luminous paint. The following from "Discovery" seems to be good and cheap: "Take a few oyster shells, and having washed them thoroughly in hot water, put them into a fire for about half an hour. When quite cool pound them fine, rejecting the grey parts. Then put the powder into a crucible in alternate layers with flowers of sulphur; seal up the lid with a paste of sand and beer. When dry, place the crucible on the fire and bake for an hour; when cold, open it, and if any grey powder is still found, remove it. Then mix the remainder into a thin paint with fine varnish. Previous to applying, the article to be painted should have two coats of white lead and turpentine to form a body-ground for the luminous mixture."

### 88.—The Double-pointed Nail.

The Durrans Patent Nail Syndicate, Limited, have drawn my attention to a speciality in the ferm of a secret nail for dowelling and other purposes in wood-working, of which I should have frequently been glad to avail myself when jointing pieces of wood together edge to edge, for which purpose I myself have been in the habit of using the ordinary wooden dowelling peg, or, more frequently, a French nail or wire nail with the head taken off and a rough point made with a file in its place; and it is surprising how a wire pin thus formed will hold pieces of wood together when used at intervals along a joint, for I have found considerable difficulty in forcing two pieces apart when thus connected, so great is the tonacity of the wire. Their utility will be at once perceived, both by the professional workman and the amateur—for the former will see how they may be made available in cabinet work and joinery, and for effecting close and firm joints in laying floor boards and other floors, as in parquetry, in which a close, firm, and invisible joint is desirable; and the amateur will recognise its services in putting together shelving, pieces of wood of narrow width to form the sides of boxes, and other jointing work in the simple wood-working that he is accustomed to indulge in. For small work the nails are cut in four useful sizes—namely, ¾ in., 1 in., 1¼ in., and 1¾ in. The shape will be seen, and the mode of using it understood, from the accompanying illustration. It is made with a projection at A, or hammer-head, by which it can be driven home into one of the pieces to be jointed, the chisel edge at B readily making its way into the material under the successive strokes of the hammer, and the piece to be attached is then placed against the point that projects from the wood into which the lower half has been driven and blocked down. When used in connecting hard wood, holes for the points should first be made with a bradawl. They are, or ought to be, obtainable of all ironmongers.

Double-pointed Nail.

The Editor.

## SHOP:

### CORNER FOR THOSE WHO WANT TO TALK IT.

*In consequence of the great pressure upon the "Shop" columns of* WORK, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* WORK *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—LETTER FROM A CORRESPONDENT.

**Incubator.**—H. E. (*South Norwood, S.E.*) writes: "In WORK, p. 461, B. A. B. describes an incubator regulator. I am afraid he is dabbling in matters he doesn't understand, as anyone who has had much to do with mercury will know that under the conditions as drawn, the expansion will be practically nil, and quite useless for the purpose indicated. Pearson's regulator consists of a metal capsule filled with (I believe) the same liquid as used in my regulator described in No. 109, and also in the article you have in hand. The inventors are very jealous of their patent rights, and will take proceedings against anyone making or using infringements. Neither will they supply the capsules except with machines."—[Unless H. E. has tried mercury under the conditions indicated, he is not entitled to say it will be useless. Doubtless some other arrangement would do better, and, it may be, some other material than mercury would be preferable. It is scarcely fair to criticise too closely a reply, unless the question is known. It may be that the querist suggested mercury; it is used in several instruments where temperature increases its bulk, and where this fact is the feature of the invention. If the receptacle were narrowed in the part occupied by the float, it would be better—that is a matter for those interested to experiment upon; if the receptacle were air-tight, no doubt it would be an improvement, but it would be too dangerously near, being a capsule, besides which, to charge a capsule some volatile oil or spirit must be found to boil at about 103°, all which would be getting very near Mr. Hearson's patent. Anyone could find a liquid boiling at the temperature required if they tried. The sketch is only a suggestion, and if it had been a perfect invention it would have been very remarkable indeed. I may as well confess that my reply was written a long time ago, and that I think the arrangement in No. 109 is better, but it is much nearer the infringement. E. is kind enough to warm me about. He criticised MR. WALKER in the same way; I hope to see his incubator soon, and that it will be beyond all criticism.—B. A. B.]

### II.—QUESTIONS ANSWERED BY EDITOR AND STAFF.

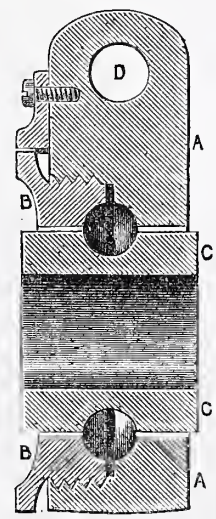
**Silver-plating Opera Glass Fittings.**—J. E. G. (*Carmarthen*).—As you have no practical knowledge of the art of electro-plating, I should advise you to send the opera glasses to a practical electro-plater or to an optician, and get the metal fittings silver-plated. As the body of the instrument is made of ivory, you would entirely spoil the colour of it by immersing it in a plating solution, and you could not silver the fittings without touching the ivory part with the solution. The fittings must be taken off, and this should be done by an optician. You will find instructions on electro-silvering in No. 112, p. 118, Vol. III. of WORK.—G. E. B.

**Electric Lighting.**—E. D. R. (*Camberwell*).—A small installation of two or three lamps in one room of a private house generally proves unsatisfactory to the owner. It is not large enough to warrant the use of a dynamo-electric machine and gas-engine or water motor to generate electricity for the lamps, and it is too large to be fed with current from a battery. A large battery will be necessary to work two or three lamps of sufficient power to light up a large room, and this battery will have to be cleaned and re-charged every day. I have yet to meet with a battery that will prove anything but an intolerable and filthy nuisance to a gentleman using it for supplying current to an installation of electric lamps. If you wish for the luxury of a few electric lamps on one or two evenings, on the occasion of a party, ball, or similar festive gathering, and can afford the luxury, I would advise you to hire the whole apparatus, with a set of accumulators, from such a house as that of Messrs. Cathcart, Peto & Radford. You will find all instructions on electric lighting in Nos. 76, 82, 89, 92, 94, 97, 99, 101, and 104 of WORK; the whole contained in Vol. II. I should advise you to read these articles before deciding on having the lamps.—G. E. B.

**Dynamo for Charging Accumulators.**—T. W. (*Bath*).—A set of *large* accumulators may be charged with current from a *small* dynamo, just as you *may* fill a large pond with water through a small pipe. Time will be required in both cases, and one will win if you have enough of it at command. But as a rule, those small machines supplied for the purpose of lighting one or two incandescent lamps may be said to be unsuitable to the work of charging accumulators. The volume of current from them is much too small, and the tension of the current too low to charge anything but a small accumulator, one or two cells at a time. Machines of the Siemens pattern, with only a two-part commutator, are specially unsuitable, because the cells are liable to discharge themselves across the brusher as soon as they get a full charge, even whilst the machine is running. This tendency to discharge may be partially obviated by making the slits on the commutator wider than usual, and altering the lead and bearing of the brushes so as to have them touching one half of the ring only when at rest. The castings advertised include those for the field magnets, armature, and bearings. These are all the castings required. All other parts are wrought iron, brass, and steel.—G. E. B.

**Series Dynamo.**—J. D. (*Halifax*).—As you get current from the machine when the fields are excited by current from a separate battery or machine, but none when the machine is set to excite its own fields, it shows that your arrangements are defective. As it is a series dynamo, you cannot expect any current from it unless you connect the terminals together, or place work of low resistance between them. If the wire connecting the terminals has a high resistance, or tho work has a high resistance, you will not get enough current through it to excite the fields; you may have reversed the polarity of the field magnets by sending current through their coils in the wrong direction. Try running the armature in the wrong direction also, and note the result. You may not, possibly (for I cannot say with certainty without knowing more about the machine than supplied in your letter)—you may not have the wire on the fields and on the armature in right proportion to each other. I do not think that the iron bed-plate would be at fault, or you would not get any results when the machine is separately excited.—G. E. B.

**Bicycle Bearings.**—H. H. (*Finsbury*).—It would be impossible for your correspondent to make ball bearings without the machinery specially made for the purpose, as the making of a ball bearing requires great accuracy. I submit a sketch showing Bown's knucklo-joint ball bearing in section. A is the body, B the screwing-in cap, C the sleeve for fixing to axle, D the knuckle joint for bolting to fork. This bearing is a patent, but the sketch will serve to show "how the side works."—A. S. P.



Sectional View of Bown's Knuckle-joint Ball Bearing.

**Hydraulic Cement.**—E. P. (*East Finchley*).—This material would be of no use as a cement for an aquarium, except for a bottom, after glazing. A recipe for aquarium cement has been repeatedly given in the "Shop" columns of WORK. Here is another:—Take ½ lb. of pitch, ½ lb. of gutta-percha, put them in an iron vessel over the fire (an old saucepan will answer very well), and melt together, adding sufficient turpentine to thin the mixture to a convenient consistency. In glazing with this cement, see that the glass is perfectly clean; the part where the cement will touch should be warmed by holding over a lamp, and when hot, smeared with the hot cement. The job requires doing quickly to ensure success.—C. M. W.

**Boot and Shoe Repairing.**—SNOB.—You want to know, and also think that many others are in the same situation, how to take off the soles when you start repairing. To deal first with riveted soles: I said, in my first article, wet the boots; if you did this they ought not to have, as you say, "literally fell to pieces;" but as that is the case, and after a second trial, too, I must own you really want setting right. I omitted telling you in my first article (as I have so seldom found it necessary, even where work was nearly to pieces, before starting upon it) that for taking the sole off a last can be put in to make a solid foundation to work on; then, after it is wet, the old sole can be prized off with a chisel, commencing at the toe, or the thinnest part: this will enable you to catch hold of it with nippers, and by this means pull off the sole with the nippers in one hand, and at the same time holding the under leather (welt, or runner, as they are often termed) down with the other. Then, should the under part still have a tendency to give way from the uppers, knock the sole back, so that it leaves the rivets sticking out, pull the rivets out with the pincers or nippers, and repeat the process till you have got the sole off without disturbing the boot, and then, before putting the sole on, the under part can be nailed down with a few short rivets to make it solid. Of course, if very long rivets have been used in the making or previous repairing, taking off the sole will, if you are not very, very careful, cause it to fall to pieces; therefore I want you to be careful, so that you will not be disparaged over so small a matter. Perhaps those you worked on had been worn rather bad, and thus made weak. This is one thing I have told you: that as your own repairer, never let them wear low—"a stitch in time," etc.—and the cheaper the boots, the more applicable this adage to boot repairing. For machine-sewn, you can follow the advice given in my next article—"Welting and Soling Hand-sewn Work"—which will also give you what you want to know about hand-sewn. I don't know how you got into such a muddle, but, any way, I will give you another system (for sewn work) which you will, perhaps, more readily grasp. When the lasts are in, and the boots wet, skive off the edge of the sole, not right through, or you may spoil the welt, but still deep enough to cut through the stitches, and cut their heads off. Then, as before, the toe can be raised or prized up from the welt; then the taking off the sole is an easy matter. I am glad you like the articles. I would advise you to look back to some of the questions answered in "Shop."—W. G.

**Book on Brazing.**—W. C. (*Paddington*).—I am not acquainted with a book treating of the different kinds of brazing, or that will give you some idea of how to do some jobs of brazing and soldering. You will find some good "Remarks on Brazing," by Mr. R. Alexander, on pages 664 and 797, Vol. I., of WORK. If you wish to know any more about the art, consult "Shop."—G. E. B.

**Sheet Metal Work.**—TINKER.—TINKER points out a slight error in size in reply to a query by BLACKSMITH (Vol. III., p. 120). It is a printer's error, due, no doubt, to bad caligraphy. Instead of "19¾ × 6¾," it should be 17 × 6¾. The size given would be for a 3 qt.—R. A.

**Garden Workshop.**—CHIPS.—I am rather afraid your ideas are too extensive for a garden workshop. You do not state whether the dead wall against which you propose to place it is as high, or higher, than the back of your shop, or if it in any way interferes with your neighbour's light. Should it interfere at all with the light or view that they may have enjoyed for any length of time, they have every right to stop its erection; and this can be done in a very friendly manner by writing a polite note to the powers that be. As to asking the permission of the district surveyor, as far as my reading and experience of the Act goes, he has no power to give you permission to build such a huge structure (for a back garden) of wood, and would at once condemn it. If you would reduce the size of the proposed shop, make it thoroughly independent, and put it on wheels, and shift it from time to time, to show that it was not a fixture, taking care at the same time not to offend your neighbour, you might get over the difficulty; but this is one of those things which depend so very much on circumstances. Many thanks for your suggestions *re* the Building Acts; but as they principally relate to matters outside the scope of an amateur or individual worker, saying nothing of the different ways in which each surveyor interprets them to suit the different contingencies to which they refer, I always find that it is better to let the surveyor read the Act, which is his business, and the tradesman to conform to his reading, which he generally has to do, no matter how well he may think he knows the extent of the Act.—E. D.

**Fairy Bells.**—F. R. H. (*Rochdale*).—I can assure F. R. H. that it is a real pleasure to help persons of his temper. He asks if I can procure him the material necessary for the construction of the instrument. As any country carpenter can supply the wood, I presume he refers to the strings and pegs. It occurs to me that there will be multitudes of readers of WORK situated practically the same as F. R. H., who lives on a moor, a long way from a town, which is visited but rarely. I cannot help remarking, in passing, that WORK must be indeed a boon to persons so isolated; and, for their benefit, I would say that Mr. Beach, Lime Street, Preston, has informed me that he will be pleased to supply small pegs at 1s. per dozen, and wire (Nos. 10 or 8) at 6d. per ring. Lest a mistake should be made, I would say that the numbers given are those known amongst pianoforte makers, and are not the same as B.W.G. I would further say, if it would help anyone, that, though I am not in business, being a minister, I shall be glad to supply anyone with such material at the price named, and postage, as well as F. R. H. A ring of wire contains sufficient to string several fairy bells.—O. B.—[F. R. H.'s suggestion that all contributors should imitate O. B., and give the probable cost of the articles they describe, is a good one, and might, with advantage to our readers, be adopted by all who answer questions.]

**Telescope Lenses.**—W. R. (*Oswestry*).—Your letter did not reach me. None of the lenses in a 36 in. telescope can in any way be utilised for a photographic camera. You will have to buy a proper lens.—E. A. F.

**Advice to a Draughtsman (Furniture, Education in).**—TAPESTRY.—You are promised a berth in a short time as draughtsman and salesman in the same firm for which you are at present shorthand writer, and you want a little bit of advice and information. Your letter has been handed to me, and if, after you had read this reply, you were to see me, I feel convinced you would be inclined to doubt my sincerity; for I gather from your letter that you are a *young* man, and I am but the same myself. However, if I am not experienced enough in the wicked ways of the world, and enabled to give you *fatherly* advice, I can, at least, give you a few

*brotherly* tips; and when we recollect that Scripture tells us our Saviour "sticketh closer than a brother," it would almost appear that the brother is the ideal of friendship in preference to the father. You must not place too much confidence in book-learning. By this I do not mean that it is advisable to depreciate *alt* such study; but you will find, if you are continually craving for more books which will stock you with information, that you will never be satisfied with your own abilities, and thus, probably, defer personal endeavours until you have perused *alt* the books that come within your reach. As you have purchased, and, no doubt, continue to buy, "Cassell's Technical Educator," and now take in WORK, you should be in a position to do something yourself in the course of a few months, with the addition of a few more publications; granting, of course, that you are a proficient draughtsman, and give your heart to your work. I am afraid you will find that the position of salesman, added to that of draughtsman, will detract somewhat from the latter profession, by reason of the chances always remaining of your being continually interrupted in your drawing; which fact may or may not disturb you, by always lying in the background of anticipation. But, there—I do not know you personally, so must not give way to anticipation myself. To be a good designer, you must strike out a path for yourself, in being original to the greatest extent that you can. There is no need to work always in one groove, and design articles only of one class, such as ordinary mechanical, folding, or combined. The readers of WORK are familiar with the three last classes of designs from my pencil, or pencils; but I am frequently designing something quite new in cabinets, sideboards, bedroom suites, chairs, tables, etc., and number among my patrons many a large firm in London. In the few years I have been in the furniture trade, I have been made aware of the fact that a mere draughtsman will be of no value in a few years' time; the demand will be for designers; but there is not much to fear by contemplating a strong competition among the latter, as, although a man may be a good draughtsman, it does not follow that he will ever be a good designer; for—although, perhaps, I really ought not to say it, and would not, were it not for the fact that I am asked by you for advice—good designers must "have it in them." Another particular thing you must be careful to study well, and that is—colour. I am looking forward to the day when every book, such as WORK, shall be embellished with diagrams and drawings in colours, tinted and shaded artistically—not the mere uniform tint over an engraved sketch, such as is common now. You will find the study of colour in application to furniture almost as difficult to overcome as the study of drawing; but aim at an end, and you will surely reach it. As regards books of designs of first-class furniture, the best "tip" I can give you is to obtain, in addition to the publications mentioned below, catalogues from as many firms as you possibly can; which task, I can assure you, you will find a most difficult and troublesome one; for a firm usually, after posting the catalogue, posts a traveller, and the catalogue has to be returned, unless the traveller's good humour is courted. An occasional peep into old bookstalls will reward you, as it has me; for you will often pick up books of work from the pencils of old designers, which will give you a true foundation on which to build your ideas. Observe all around you. If you see anything at all striking, retain it in your memory. We can be original, but our ideas cannot be entirely new; it is the form in which we apply them which gives the originality. For instance, one part of an article the Editor has in hand (which you will recognise when published) was really suggested to me by the well-known boat-swings, so arranged in groups of four, that they work round, up and down, and yet each always retains its horizontal position. Sometimes an idea occurs to me out of my own head; but I feel sure that, were search made, the same idea would be found, applied differently, in a different form of construction. By all means subscribe to *The Cabinet Maker* (Mr. Benn, City Road, London) and *Furniture and Decoration* (Messrs. Smith & Botwright, 6, Eldon Street, Finsbury, London, E.C.), each 6d. monthly, and both first-class books, exclusively, as their titles indicate, devoted to furniture and furnishing. *The Furniture Gazette* (Messrs. Wyman and Son, Queen Street, Holborn, W.C.) will also help you. And you may get some architectural ideas from *The Builder* and *The Building News*. Get an index of Vol. I. of WORK, and select from it those numbers in which my fellow-contributors have given instructions in joinery. I daresay you possess Messrs. Cassell & Co.'s catalogue; in addition, get Messrs. Blackie & Son's catalogue, from Old Bailey, London, for drawing and colouring. Always satisfy yourself in your work, and you will be sure to satisfy your employers. Become on friendly terms with the masters and men in as many cabinet-making shops as you can: you will find the British workman an obliging and friendly fellow. Art schools are all very well; but my opinion is that the learners must, naturally, always work in the same groove, and become so used to it as to be too dilatory to strike out a path of originality for themselves. I have replied to you at some length, because I feel interested in you, and would endeavour to make your personal acquaintance, were you resident in London instead of in Bristol. I feel convinced that the Editor will not condemn me for so long a reply to a struggling young fellow, nor for asking you to write and tell of your progress in a few months' time. I wisb you well.—J. S.

**Valve.**—A YOUNG ENGINEER.—I suspect the reason why your valve face does not stick to cylinder is because the opposed faces are not scraped perfectly clean. Clean surfaces, covered with a thin layer of solder, raised to the proper temperature, but not overheated, and then pinched together and allowed to cool, cannot fail to adhere. —J.

**Use of Cardboard.**—A. E. R. (*Kingston*).—The variety of fancy articles which may be made from scraps of cardboard is almost endless. Among light occupations, few, perhaps, are prettier or more interesting than making architectural models in this material. The appliances needed are few, beyond scissors, a penknife, and gum. The block form of the building is usually glued together in thin wood, which is pierced with openings for windows, doors, etc.; this is coated with cardboard, bits being gummed upon it to form buttresses, pinnacles, mullions, traceries, etc. Wherever right angles occur, they are formed by scoring the card half through and bending it. Glass is fixed in the window-openings, and on this the tracery, cut out in cardboard, is gummed. Any moulding, however complicated, may be imitated by cutting out in card, and gumming one member of it over another. The effect of carving is best got by a little lining in Indian ink. With merely careful and patient work, admirable representations of buildings may be thus produced. Cardboard models may either be left white, or coloured to resemble the actual buildings. Ruins may be prettily imitated by vencering with sand-paper, marking out the stones, etc., with black or brown transparent varnish colour, and gumming on dried moss to represent ivy.—M. M.

**Labyrinth Puzzle.**—P. C. N. (*Shrewsbury*).—As merely application for patent has been made, there will as yet be no means of ascertaining the nature of the rival invention. P. C. N.'s idea is certainly ingenious, and, I should think, worth some little risk. In so simple a case, he might well apply for provisional protection without employing a patent agent. He would, of course, specify for "Improvements in Labyrinth Puzzles." Perhaps he might find some tougher composition in which the lines could be impressed better than the fragile one named, or some other kind of ball desirable; and would do well so to frame his specification as to include such variations. The *design* of the labyrinth should be protected by registration, fee 10s. If P. C. N. will cast his eye over the recent columns of "Shop," he will find there the address of an agent who communicates between inventors and manufacturers. Perhaps, when protected, P. C. N. might do well to put himself in communication with the rival above alluded to.—C. C. C.

**Drills.**—W. J. B. (*Sidbury*).—I am sorry that I cannot say certainly where the diamond drills are to be procured, not having had occasion to use them. But try Holtzapffel, Charing Cross; Pfiel, John Street, Clerkenwell; and Morris Cohen, Kirkgate, Leeds. To make and harden small drills, proceed thus: Procure the best possible steel wire; sometimes large sewing needles are used for the smallest. Draw the temper by making red-hot and cooling slowly; flatten the cutting end with a blow or two of a heavy hammer. The fewer the blows the better, because they tend to render the steel brittle. The cutting facets are then shaped with a file or on a hone. These small drills are usually hardened and tempered at once by heating them to a red colour, and plunging them into the body of a wax or a tallow candle. They may be heated on a piece of charcoal with the blowpipe, or on a red-hot iron bar. The cutting-point only should be hardened. Drills that are not very small require to be first hardened, and then tempered by the methods usual with engineers' cutting tools.—J.

**Model Horizontal Engine.**—F. C. (*Cardiff*).—It does not appear, definitely, of what parts you require the sizes. You say you have the "cylinder, etc." The "etc." may mean anything, or include everything. However, the following proportions may be of service to you, and any others you may require I shall be glad to give if you write again:—

| | |
|---|---|
| Piston | $\frac{1}{8}$ in. thick |
| Piston-rod | $\frac{1}{4}$ „ diameter |

(The length must be sufficient to clear the gland by about $\frac{1}{8}$ in. at least.)

| | |
|---|---|
| Connecting-rod, at ends | $\frac{1}{8}$ in. diameter |
| „ at centre | $\frac{3}{16}$ „ „ |
| „ | 4 „ long |
| Piston-rod crosshead | $\frac{1}{4}$ „ wide |
| „ | „ long and high |

(Groove out $\frac{1}{8}$ in. wide and $\frac{1}{16}$ in. deep top and bottom for guide-bars.)

| | |
|---|---|
| Guide-bars | $\frac{1}{4}$ in. wide |
| „ | $2\frac{1}{2}$ „ long |
| „ for $\frac{1}{8}$ in. of central width | $\frac{3}{16}$ „ thick |
| „ for each $\frac{1}{16}$ in. of side do. | $\frac{1}{8}$ „ „ |

(With $\frac{1}{8}$ in. diameter distance bolts at ends.)

| | |
|---|---|
| Valve-rod | $\frac{1}{16}$ in. (full) diameter |

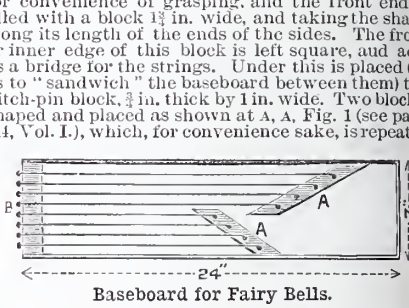
You will, of course, lay the lines down on paper before making the model. The travel of slide-valve and throw of eccentric will depend partly on width of port. I cannot give you the length of piston-rod, because I do not know length of gland or how much clearance (over the 2 in. stroke) you have in your cylinder; but you should find no difficulty in setting this out.—F. C.

**Chiffonier.**—A. W. M. (*Liverpool*).—The design you submit for chiffonier is not of sufficient merit to publish in WORK. If you send your full address, and a stamp, the MS. will be returned to you.

**WORK Numbers.**—INDEX.—The pages you require cover so many numbers, that it would be better for you to buy Vol. I. of WORK, containing a year's numbers.

**Wood Screwing Tool.**—W. H. N. (*Oldham*).—This is one of Peugeot Brothers' tools. Any tool-maker will procure it for you.

**Fairy Bells.**—CORKONIAN.—If CORKONIAN will turn to page 814, Vol. I., of WORK, he will find drawings of "fairy bells" which will help him very considerably in his construction of this instrument, which was originally known as "Oxford Chimes," and the essential character of the tone of which is the floating, waving quality imparted to it by the method of playing, viz., grasping it firmly with both hands, and swinging it about from side to side or in circles, while the notes are being plucked *with the thumbs*. This character is entirely lost by the instrument being placed on a table or fixed rest while being played, it being then, although still very sweet, very little, if any, better than the tone of a Prince of Wales's harp or toy zither. In the drawings above referred to, one of the original or eight-stringed instruments is shown; but there is nothing to prevent CORKONIAN making one of ten, twelve, fifteen, or, in fact, as many strings as his hand is large enough to cover, or his muscles strong enough to swing; bearing in mind that the more strings there are, the wider and longer must the instrument be, and the heavier and more unwieldy must it become, if the character of its tone is to be retained. The one shown in the drawing consists of a baseboard of pine, 24 in. long by 7 in. wide, and $\frac{5}{8}$ in. thick, and having sides and back end of the same material, about 2 in. deep, which thus forms a shallow box or tray. The sides are shaped as shown for convenience of grasping, and the front end is filled with a block $1\frac{3}{4}$ in. wide, and taking the shape along its length of the ends of the sides. The front or inner edge of this block is left square, and acts as a bridge for the strings. Under this is placed (so as to "sandwich" the baseboard between them) the hitch-pin block, $\frac{3}{4}$ in. thick by 1 in. wide. Two blocks, shaped and placed as shown at A, A, Fig. 1 (see page 814, Vol. I.), which, for convenience sake, is repeated



Baseboard for Fairy Bells.

here, occupy the interior, and are each $1\frac{1}{2}$ in. wide and $\frac{3}{4}$ in. deep. Observe, these two latter are placed in *opposite* diagonal directions, so that the shortest string may come in the centre. If they were placed in the same line, the shortest string would come on the outside, and the first part of the scale would have to be played backwards. No bridge is necessary on the front of these blocks, as the strings are wound round the wrest-pins so as to remain quite clear. All these blocks should be made of clean beech, and each should be planed perfectly true on the under side, so as to form a thoroughly good joint with the baseboard. If this is done, no screws will be necessary; although it would be safer, perhaps, to use a few in the event of the instrument being exposed to damp. Having fitted your wrest-pin blocks, mark off the length of each into four, five, or six equal parts, according to the number of strings you intend having (allowing $\frac{3}{8}$ in. in width on the baseboard for each additional string), and leaving 1 in. clear of the block at each end; and then, on these marks, bore the holes for the wrest-pins, which are ordinary piano pins, and must fit tightly. The hitch-pins are ordinary round-headed screws, $\frac{3}{8}$ in. long, and their position is determined in the block, into which they are to be inserted by dividing it into an equal number of spaces corresponding with those in the wrest-pin blocks. A cover, 18 in. long (which should be made to slide in and out *from the front*, or may be screwed on), must be provided, and should be of $\frac{1}{4}$ in. mahogany or cedar, with a brace, $\frac{3}{4}$ in. wide and $\frac{1}{4}$ in. thick, screwed and glued across its top front edge, to prevent warping or splitting. In this cover should be cut two *f* holes, which should come directly over the wrest-pins, and permit of tuning the instrument without withdrawing the cover; this latter operation being only necessary when a new string has to be put on. Previous to stringing up, size and varnish the inside with good spirit or copal varnish, and, if you wish it to look well, French polish the outside. This, of course, is optional. In stringing up, the eyes should not be twisted, but should be made thus: Fix a wire nail or peg, slightly larger than the hitch-pin, in a vice, and, taking the string in the left hand, grasp the end with the right, and take a turn round the peg, and then two turns round the string itself, close up to the peg; then cut off the free end of the wire, so as to leave a "tail" $\frac{1}{4}$ in. long. This tail comes flat on the block, and is quite sufficient to prevent slipping, and at the same time it presents no rough or jagged end to injure the hands or dress. When tuning, roughly pull up to within a note or two of the pitch required, and afterwards gradually raise to about half a note above; then, with a piece of wash-leather, rub briskly up and down each string with a moderate amount of pressure. This will stretch the wire, which should then be pulled up again to pitch and left for an hour, after which it may be put into proper tune, remembering that

the highest note is the right-hand centre one, and that the first half of the scale goes to the right hand, and the second half to the left, from the left-hand centre note. Everything necessary for the construction of these instruments can be obtained of Messrs. Chilvers & Co., 10, St. Stephen's, Norwich. —R. F.

**To Mount Maps or Plans on Linen or Calico.** —ONYX.—Tack, very tightly strained, on a piece of board, or, if very large, on a frame, a piece of calico or linen, of the requisite size, allowing an inch and a half margin beyond size of map. Give this a good coat of strongish size. When nearly dry, take your map; sponge the *back* with clean water. When well damped through, paste with well-strained paste, made with a pinch of alum, as before described in our columns; then lay down on canvas, pressing all over with roller or clean linen cloth. When dry, it can either be cut out and framed, or sized and varnished and mounted on rollers.—F. B.

**Painting on Glass.**—S. E. R. (*Rye*).—The glass used by glass painters will stand the test as recommended for silver, if you take the precaution to warm the glass gently, at first, instead of plunging direct into the fire. The very thin glass is that used for microscopic slides, but its very thinness is against its use in large pieces. Any good firm of glass merchants, such as Hetley, Soho Square, would supply you with what you require, and would also undertake to bend glass for you. The silvering can also be done by such firms; and probably the process you mention as a German one is the one used by London firms. Great improvements have been made this last few years in amalgams for silvering glass, quicksilver being more sparingly used than heretofore. Quicksilver itself will not stand a great heat, as it becomes a vapour if subjected to severe heat.—F. M.

**Wood Carving Manual.**—P. 2. (*Nottingham*).—P. 2. is recommended to write to the School of Wood Carving, South Kensington, enclosing 1s. 1d., and ask for the book to be sent him entitled "Hints on Wood Carving for Beginners," by E. Rowe.—W. E. R.

**Wood Carving Book—Covers for WORK.**—EDGAR L. R. (*Oxford*).—E. Rowe's "Hints on Wood Carving for Beginners" will be found most useful, and can be had post free for 1s. 1d. from the School of Wood Carving. If you want designs, write to B. T. Batsford, Publishers, 52, High Holborn, and ask them to send you their list of books on wood carving. They sell very good photographs in a folio of Signor Prullini's work. And from the School of Wood Carving you can get a folio containing 18 plates of photographs from carvings in the South Kensington Museum for 13s., post free, or single plates 9d., post free. F. Miller's "Wood Carving," published by Wyman & Sons, Great Queen Street, W.C., is a good, useful book on the subject. Covers for binding volumes of WORK can be had of any bookseller, or of the publishers, Cassell & Co., Limited, London, E.C.—W. E. R.

**Electric Bell Failures.**—A. W. S. (*Enfield*).—As your bells ring in dry weather, but fail to ring in wet weather, it shows that you have fixed some metal parts on direct to wood, instead of fixing them to a metal base. As the wood absorbs moisture from the damp air in wet weather, it swells, and alters the adjustment of the two metal parts fixed to the wood base. The defect may be on the bells, but is more likely to be in a push or a switch of bad design or construction. Such hard woods as teak or box should be employed in switches and pushes, and the contact pieces of metal must be furnished with a spring, to take up slight alterations in adjustment caused by the wood swelling or shrinking. —G. E. B.

**Netting Needles, Twine, Cotton, etc.**—G. T. (*Old Shildon*).—Ironmongers, dealers in fancy goods, and drapers, will generally supply or get for customers all the requisites for netting. Oiled twine, as used in making herring nets, may be got through any dealer in fishing tackle, of which there are generally one or two in each town.—G. E. B.

**Electrical Matters in Back Numbers of WORK.**—J. S. (*Kirkcaldy*).—As a mere list of the back numbers wherein papers on electrical matters have appeared would fill one column of "Shop," I hope you will be so kind as to excuse me the task of writing it. An index to Vol. I. will show you that there have been very few numbers in which there has not appeared some paper on electrical matters, or some useful reply in "Shop" on the same subject.—G. E. B.

**Galvanic Battery.**—J. S. (*Kirkcaldy*).—After all this time, I learn from your last letter that the thing you desire is not a galvanic battery but a medical coil. It is true that a coil must be worked by a galvanic battery, just as a steam boiler will be needed to work a steam-engine; but the battery will be useless without the instrument named a coil, as you could not get a shock from the battery alone. Instructions and illustrations showing how to make such an instrument as you require will take up too much space in "Shop."—G. E. B.

**Patent Agent.**—A. W. G. (*Jersey*) will probably, since the date of his letter, have read in "Shop" the address of a firm of London patent agents whose professional reputation is, we believe, beyond question. If not, we must ask him to refer to our answer to W. G. S. (*Bristol*) in a recent issue.—C. C. C.

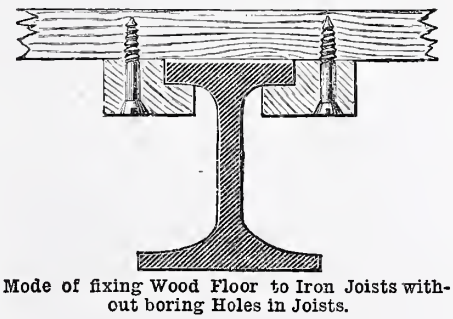
**Sample of Red Wood.**—E. L. H. (*Liverpool*).—The sample sent is a piece of padouk wood, and comes from India, most of it being brought from Calcutta. It is much used in the place of mahogany, being richer in colour, and, if grown on a favourable soil, of splendid figure. It is imported in planks of about 4 in. thick, and up to about 24 in. wide. It is very hard working, but gives great satisfaction when finished. The price is about the same as mahogany, and can be bought at many of the London yards.—A. J. H.

**Book on Locks.**—C. H. C. (*Pimlico*).—I do not know of any book published relating to locks and keys. The steel wire used for picks is usually about 11 or 12 W. G., tapering towards the end. It would be better to purchase them than attempt to make them. The cost is about 6d. each.—T. W.

**Stationery Holder.**—M. A. (*Suffolk*) asks for a full-size design for the Stationery Holder given in "Shop" supplement of No. 66. It is impossible for contributors to accede to such requests as these, involving, as they would, an expenditure of much time and trouble.

**"Shop" Insertions.**—L. B. (*West Bromwich*).—No charge whatever is made for any communication appearing in "Shop." You and others may make any remarks which are likely to be of service to readers of WORK, and, if of value, your communication will be printed, as a gratuitous contribution, in Sections 1 or 4.

**Laying Warehouse Floor.**—A. F. R. (*Birmingham*).—The question put has attached to it very difficult conditions, which, for the benefit of other readers, ought to be stated: Boards, 11 in. × 3 in., not to be reduced; no nails on surface; provision made for repairs; and to be ploughed and tongued; joists of iron, 3 ft. between centres, and 5 in. wide on top flange; and no bolt-holes are to be made in the joists. I fear that A. F. R. will have to modify one of these conditions, for there is to be provision for easy repair, which is impossible with ploughed and tongued work, especially as the tongue generally used is iron hooping. If A. F. R. will *rebate* the



**Mode of fixing Wood Floor to Iron Joists without boring Holes in Joists.**

under edges of the flooring, he may have a strip to exclude dust and draught; but it is, I admit, inferior to an inserted strip in a groove, as in the usual manner. Seeing, however, that the floor is 11 in. × 3 in., I should not insist on easy repairing. Few warehouses survive fire-risks long enough to require repairs to so stout a flooring. If the load on the floor is fairly uniform, fixing might be dispensed with; but fixing adds to the strength of a floor very much, and the simplest plan, without making holes in the joists, would be to make some rebated strips (3½ in. × 2 in. would do), and screw them underneath. Of course, I am assuming room enough to admit of this, which is probably the case. The strips sketched might be put on every or on alternate joists.—B. A. B.

**Thermometer and Barometer.**—IN DOUBT.—Your difficulty arises from the circumstance that the imprisoned air varies in volume, not only in proportion to its temperature, but also in proportion to the pressure to which it is subjected from time to time, one of these factors—the temperature—being under your control, the other not so. Your letter shows that you are unacquainted with the laws which govern the volume of gases, one of which is that the volume is directly proportional to the pressure acting upon the gas under observation. For instance, a volume of air—which is a mixture of gases—measuring exactly 1 cubic ft. at the normal pressure of about 15 lbs. per sq. in., would only occupy one-half that space under a pressure of 30 lbs. per sq. in.; whereas it would occupy double the space were the pressure decreased to 7½ lbs. per sq. in. The pressure of the atmosphere is constantly varying, and, consequently, the bulk of imprisoned air contained in your apparatus varies also, independently of the temperature; hence the corrugated disc—the most yielding part of the chamber—rises to different heights on different days. You might overcome your difficulty by filling the chamber with some liquid, such as water or alcohol, or a mixture of these if the boiling-point of the liquid chosen be in excess of the greatest temperature required; but you must not lose sight of the inflammable nature of alcohol. Would a metallic thermometer suit you? If so, such an article may be readily made and adjusted to act at any desired temperature, it being only necessary to take two long thin strips of brass (or zinc) and steel —one of each—say, 1 ft. long, ⅛ in. wide, and 1/32 in. thick, and carefully rivet them together at intervals of half an inch. Such a compound bar will *bend* under the influence of heat, and, if it be fixed by one end in a vertical position, the fixed end uppermost, the free end will move to and fro as the temperature varies; and you could readily arrange matters so that contact would be made at any desired temperature. If the heat required be not sufficient to melt the solder used, the two strips may be soldered together throughout their entire length; but in this case you will have a curved instead of a straight combination, on account of the unequal expansion caused by the heat applied whilst soldering. The curvature may, however, be corrected by placing the strip, hollow side uppermost, on a block of hard wood, and applying the "pene" of a light hammer in a succession of light blows across the strip, the entire length being submitted to this hammering, until the strip has been sufficiently straightened, when the hammer-marks should be erased by the application of a fine-cut flat file. You will, of course, understand that the entire length of the compound metallic strip must be submitted to the temperature to be measured.—QUI VIVE.

**Perfect Safety Bicycle.**—E. G. F. (*London, W.*). —A machine similar to Fig. 3 (see WORK, No. 66, Vol. II.) is manufactured by Humber & Co., Limited, of Holborn Viaduct. There must be other makers, but I cannot call to mind any others.—H. B. P.

**Micro. Mounting.**—J. P. (*Brighouse*).—The thin metal caps referred to for securing cells for mounting semi-opaque objects, as used by Mr. Enoch, may be obtained from most of the leading opticians who deal in micro. specialities, or from Messrs. Thompson & Capper, 4, Lord Street, Liverpool.—A. T. S.

**Incubator.**—L. G. W. (*Barnsbury*).—I should strongly advise you to send for Hearson's little manual, entitled "The Problem Solved," price 1s. As you have one of their incubators, the manual would be of special service to you. As to making a regulator to suit Hearson's Incubator, I have no doubt that it is beyond the abilities of an amateur. If I could be certain of the exact ingredients of the capsule, I would not advise anyone to make one, unless certain as to the ability of the worker to do the necessary soldering. Probably, the liquid used is some volatile spirit, or ether; in any case, its use is the special subject of Mr. Hearson's patent, and the company sell all the fittings at very moderate prices.—B. A. B.

**Piano Making.**—J. M. (*Midhurst*).—You seem to be in a little difficulty, but I think I shall be able to set you right. The lines made on p. 452 are not intended to show the setting-out of the strings, but are merely the bracings. The measurements are for a 7-octave piano. The back is quite wide enough if you have made it 4 ft. 2 in. Take the measurements on p. 502, second column, 41st line. Your first note will be 2½ in. from the treble end, and your last note 47½ in. This will leave you 2½ in. from the last bass note to the outside edge of your back. I expect your compasses have gained a little with moving them. Contract your compasses a shade, until you get the 85 notes within the limit of 2½ in. from each side of the back. Be careful to put your scale to the bottom edge of wrest-plank (see p. 565, third column). I think you will surmount your difficulty with a little patience. If you have got on so far, I am sure you will be equal to this. You will see on p. 502, second column. Glue all edges, except the bottom. This will answer your other question.—T. E.

**Cassell's "Popular Educator."**—W. B.—Vol. III. is now complete, and can be had of any bookseller, or of the publishers, Cassell & Company, Limited, London, E.C.

**Camera.**—I. T. W. (*Tamworth*).—The camera you name is very good, considering the price. The material and workmanship in the higher-priced instruments by the leading makers are, of course, superior, and will stand very much more wear and tear. *Any* plates may be used in *any* ordinary camera, provided they are the right dimensions. The make of plate has nothing to do with it. The detective camera mentioned is little better than a toy, and the work obtained by it must be judged accordingly. Occasional articles appear in WORK on this subject.—D.

**Camera.**—I. H. (*London, E.*).—Make a pattern in paper as a guide. If the measurements of the two ends are correct, lines drawn from the extreme corners of the larger to those of the smaller end will be quite right to fold by. The zigzagging of the bellows is, of course, horizontal. The principal difficulty, which is soon mastered, is pinching the corners into form, to make the bellows work smoothly. It must not be forgotten to allow a little for overlap in joining up.—D.

**Tempering Axes.**—J. S. (*Longsight*).—You must heat the axe to a low red, and quench in salt water. Then let down to a brown or a blue, according to the steel, and quench for tempering. If you find the temper is soft, gradually experiment with lighter tints, ranging between dark straw and brown.—J.

**Pipe over Plinth.**—J. G. (*Glasgow*).—I have looked at your model, and there is no way of getting at the angles except by drawing out the pipe in elevation and in front view, and bisecting the angles. You need not seek for any other way, for there cannot possibly be one better or more accurate. It is one of the commonest and simplest jobs in practice. —J.

**Ready Reckoner.**—J. G. (*Bradford*).—Try "Quantities and Measurements," by A. C. Beaton; price 1s. 6d. Published by Crosby Lockwood & Co. 7, Stationers' Hall Court.

**Connecting Rod Brasses.**—BRASS.—Such brasses are not usually lined out, but are centred tentatively in the lathe, so that all parts shall hold up to size. If lined out, you will simply clip the two halves with packing pieces between, insert a temporary centre, and from it strike the required circle.—J.

**Slide Rule.**—F. W. (*Worcester*).—The best book is "The Theory and Practice of the Slide Rule," by Campbell. Published by Spon, 125, Strand, London, W.C.—J.

**Small Iron Castings.**—S. & B. (*Bristol*).—The only way is to use very soft pig—No. 1 Scotch, with no admixture, or very little, of scrap.—J.

**Designs of Working Cardboard Models.**—C. W. S. (*Northallerton*).—Inquiries made by me fail to elicit any information as to where these are to be obtained. Probably some reader may know whether they are supplied, and if so, by whom. I should advise you to ask at the shops where working models are exposed for sale.—J. S.

**Triple Expansion.**—KIDDERMINSTER.—To give our correspondent the particulars he requires, and explain them clearly so as to be of any use to him, would take up far too much of our already limited space; as the subject is not of sufficiently general interest to our readers or the public, we cannot feel ourselves justified in so doing. The best thing our correspondent can do is to refer to "Seaton on the Marine Engine," where he will find the subject fully gone into, and all the necessary information fully set forth.—C. E.

**Gold Paint.**—W. H. F. (*Kingston*).—You say you have tried several ways of using bronze powder as a gold paint, but you do not state how you used it. Have you tried mixing it with gold size? This is what the majority of gold paints consist of. Gold bronze should be protected by a coat of varnish, or it will turn black.—R. A.

**Embossing Dies.**—C. S. (*Manchester*).—I do not think you need trouble about allowing for the thickness of the metal. The metal used with these dies for stamping name-plates, trade-marks, etc., is usually very thin, and if you get your two dies to fit nicely together, the result (for thin metal) will be satisfactory.—R. A.

**Sheet Metal Working.**—J. H. B. (*Norton*).—For instructions in sheet metal working, get the numbers of WORK that articles on the above subject have appeared in, and look out for others that have yet to appear. Cassell's "Drawing for Metal-plate Workers" is a useful book at a low price (3s.). "Millis' Sheet Metal Work" (Spon) is also a first-class work, but high in price (9s.).—R. A.

**Enginc.**—J. E. (*Cardiff*).—¾ in. bore by 1½ in. stroke would be about correct for such a boiler.—J.

**Sanitation.**—A. Y. (*Deptford*).—The following are good books:—"Sanitary Engineering," by Baldwin Latham, price £1 10s.: published by Spon, 125, Strand; and the "Municipal and Sanitary Engineers' Handbook," price 12s. 6d., same publisher.—J.

**Cover and Advertisements.**—W. N. H. (*Bradford*).—Thanks for your suggestions, which shall have consideration.

**Waterproof Glue.**—F. B. (*Aldershot*).—If you are thoroughly assured that no remissness exists on your part by way of address or postal delivery, why not take the advice of a solicitor?

**Saws.**—F. C. (*Belfast*).—Please state your trouble more definitely, and say whether it is a circular, frame, or band saw. If also you couch your question in a becoming way, you may rely upon a civil answer.—A. R.

**Refrigerator.**—DOUBLE GLOSTER.—From the sketch you send of an American refrigerator which you are using, but "find in practice an utter failure," it appears to be constructed upon sound principles, the only thing omitted is that of a small ventilator in the top—which you have probably left out of the sketch: you further say "that the heat to be kept is that of frozen New Zealand mutton." Does it not strike you that this is expecting too much? The temperature of your refrigerator, and, indeed, any refrigerator short of an *ice making* machine, will be *below* freezing point, since the cooling depends upon the *melting* of the ice, so that the work power you put in is 32° Fahr. at its best; the work done must be something less, useful enough for ordinary purposes, but insufficient to arrest the thawing of frozen meat; clearly, it would be of no use to introduce any mechanical means of moving the air.—C. M. W.

## III.—QUESTIONS SUBMITTED TO CORRESPONDENTS.

**Ready Reckoner for Timber Trade and Glass Trade.**—J. G. (*Bradford*) writes:—"Could some kind reader oblige me with title of book and publisher for joiners' and builders' tables, showing number of superficial feet in any given measurement of wood or glass?"

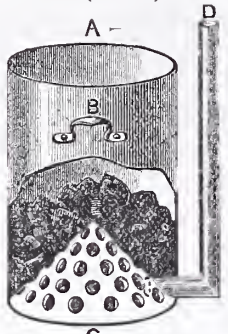
**Water-Colours.**—J. P. (*Belfast*) writes:—"Will any kind reader of WORK inform me how to make moist water-colour paints? I have made some, but find they get as hard as stone in a day."

**Ivory Tablets.**—SEA GULL writes:—"I should be glad to be informed where I can get ivory or xylonite name tablets as used by makers of cameras and dark slides. I want some wholesale maker."

## IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Tuck Pointing.**—M. (*Bishop Auckland*) writes, in reply to SLATER (see page 462, No. 133):—"If you refer to No. 72, Vol. II., of WORK, you will find instructions for tuck pointing brickwork; and to No. 121, Vol. III., instructions for tuck pointing stonework. If you require any more information than is there given, if you will write again I shall be glad to assist you."

**Heating Water for Bath.**—C. H. (*Stroud*) writes in answer to ROUND O (see page 414, No. 130):—"The only way of heating cold water in a bath is by using a charcoal heater, similar to sketch, in which A is round sheet-iron cylinder; B, handle on either side for lifting; C, perforated cone grating; D, pipe reaching under perforated cone, the air rushing down pipe and up through the perforated cone, acting as a blower, and keeping the charcoal in a lively state. Place apparatus in bath of cold water and let it remain until water is sufficiently heated, then remove from bath room."



Charcoal Heater for Bath.

**Wicker Stains.**—L. S. L. (*Kirkcaldy*) writes to A. B. (*Westminster, S.W.*) (see page 462, No. 133):—"Wash the wicker, after being thoroughly cleaned, with a solution of eutch (catechu). The solution may be about 1 eutch to 20 boiling water. Allow to dry, and coat with solution of bichromate of potash of about same strength. Expose to the light until dry, and repeat the bichromate coating until the desired shade is produced. The colour is permanent, and can be left unvarnished if you like. I think you will like this method. Your chair was very likely coated with common brown varnish—not stain."

**Heating Room.**—RUSSELL writes to C. J. P. (*Derby*) (see page 462, No. 133):—"If you have domestic hot-water apparatus, I should carry pipes from them, you would find it cheaper than any other method. I shall be pleased to send you drawing for same if you can show existing pipes."

**Dry Battery.**—H. E. (*South Norwood, S.E.*) further writes in reply to J. A. M. (*London, N.W.*) (see pages 14, 110, and 203, Vol. III.):—"I must apologise for not noticing your letter before, but have been very busy for some time, and have not looked at some numbers. Going through this evening I came across yours, and hasten to reply. I am sorry to hear you could obtain no result after following my instructions, which I have re-read. I had not tried the first receipe, but gave you what I believe to be Gassner's mixture. I culled it from a reliable source, and have no doubt as to its correctness. This being so, I cannot account for your failure. The second recipe (with agglomerate Leclanché) I have tried, and found to work well. Here are some more which you might try. (1) Permanganate of Potash Dry Cell.—Get a pint jar, line inside with sheet zinc, allowing lug for connection, and well amalgamate all except the lug. About three parts fill the jar with a saturated solution of sal-ammoniac, add an ounce of permanganate, and well mix, then stir in sufficient plaster of Paris to make a thick cream. Insert a good-sized carbon plate in centre, and as soon as set, seal over the top with melted paraffin wax. (2) Mescrolo Dry Battery.—The mixture for filling the dry cells, prepared by M. A. V. Meserole, is said to consist of the following solid ingredients in the form of powder: charcoal, 3 parts; mineral carbon or graphite, 1 part; peroxide of manganese, 3 parts: lime hydrate, 1 part; white arsenic (oxide), 1 part; and a mixture of glucose and dextrine or starch, 1 part; all by weight. These are intimately mixed dry, and then worked into a paste of proper consistency with a solution composed of equal parts of a saturated solution of chloride of ammonium (sal-ammoniac) and chloride of sodium (salt) in water, to which is added one-tenth volume of a solution of bichloride of mercury (corrosive sublimate), and an equal volume of hydrochloric acid (spirits of salts). The fluid is added gradually and the mass well worked up. Elements and sealing as before. No. 1 should give a capital cell; of No. 2 I know nothing, but if fond of experimenting you might try it. I shall be pleased to know how you get on. A letter addressed to me through the Editor will reach me. I will also experiment a little if I can find time."

## V.—LETTERS RECEIVED.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—B. B. (*Deptford*); F. H. J. (*Angelica*); E. P. S. **The Talmer does the Best.**—Illustrated pamphlet of this perfect Hand Camera 2 stamps.—TALBOT AND EAMER, Blackburn.

**Photographic Apparatus,** list 2 stamps. Dark Slides, best quality, fitted to any camera: ¼ plate, 5s.; ½ plate, 9s. 3d. All sizes made.—TALBOT AND EAMER, Blackburn. [18 R

**Fretwork Designs.**—Books of 12, 7d. and 1s. 1d.; 40 smaller designs, 7d.; sample sheet of 6, 2½d. Fretwood from 4d per foot.—TAYLOR'S Fretworkeries, Blackpool. [19 R

**Fretwork Tools and Materials** at CLARKE'S Tool Stores, Fore Street, Exeter. New Illustrated Catalogue post free. [20 R

**Joiners' Tool List,** post free.—BOOTH BROTHERS, Dublin. [21 R

**Picture Moulds.**—15 to 25 per cent. saved. Send for wholesale list, one stamp.—DENT'S, Importers, Tamworth. [3 R

**Catalogue of New Tools, 6d.**—Monthly Register, containing details of upwards of 3,000 (three thousand) new and second-hand Gas and Steam Engines. Boilers and every description of Tools and Plant wanted and for sale; cash or hire purchase.—Call at 100, Houndsditch, London; or send 4d. for Register to Britannia Co., Colchester. [7 R

**Violinists.**—Italian perfection gut strings, E, 7d.; set, 2s. 11d., post free.—E. BAKER, Clarence Street, Dartmouth, Devon. [1 S

**Valuable Bargain.**—Fine mellow-toned violin in perfect preservation; complete with bow and baize-lined case. Take 14s. 6d. for the lot; violin alone worth double. Money willingly returned if not approved. About 20s. worth of music (unsoiled) given in free.—GRAHAM, College Buildings, Ipswich. [2 S

**The Buyers' Guide** to the best Books on Mechanical Subjects, with table of contents, price 6d. In cloth, 1s. 6d.—Published by BRITANNIA Co., Engineers, Colchester.

**Lettering and Sign-Writing made Easy.**—Also full-size diagrams for marking out eight alphabets, only 1s.—F. COULTHARD, Darlington Street, Bath. 100 Decorators' Stencils (60 large sheets), 2s. 6d.

**Fret, Carving, and Repousse Patterns.**—100 of either, full-size, 1s.; 35 Fret Photo Frames, 1s.; 30 Fret Brackets, 1s.; 100 Sign-writer's Stencils, 1s.; 300 Turning Designs, 1s.; 400 small Stencils, 1s.; 500 Shields, Monograms, &c., 1s., postage free.—F. COULTHARD, Darlington Street, Bath (late Bournemouth). [3 S

**Anti-vibrator Castings, Brass.**—Offers.—Apply, SMALL, Wenlock Buildings, Ironmonger Row, E.C. [4 S

**Wood Carvers** should send for HATTEN & BEDDALL'S price list of Wood-carving tools, 69, Malvern Hill Road, Birmingham. [23 R

# FRETWORK AND CARVING.

*Highest Award—GOLD MEDAL.*

MACHINES, DESIGNS, TOOLS, WOOD, MIRRORS, HINGES, AND VARNISH, &c.

Fretwork Outfits, 1s. 4d., 2s. 6d., 3s. 6d., and 5s. 6d. each.

*Sets of Twelve Best Carving Tools, with Boxwood Handles, 10s. free.*

All Materials and Tools supplied for Fretwork, Carving, Picture Framing, Brass, Leather, and Burnt Wood Work.

Our Catalogue, acknowledged the most complete, with 1,000 Illustrations, and all Instructions, free for six stamps.

**HARGER BROS., Settle, Yorks.**

# Poker Work.

"VULCAN" Machines and Patent Points for this beautiful and decorative work to be obtained of all Fancy Goods Dealers and all Art Depôts, or direct from ABBOTT BROS., White Horse Buildings, 100, HIGH HOLBORN; or Southall.

(See Notice in "WORK," November 7.)

LEE'S ILLUSTRATED CATALOGUE OF SELECTED

## AMERICAN TOOLS and MACHINERY.

Screw Cutting and other Lathes, Chucks, Slide-rests, Lathe Dogs, Polishing Lathes, Drilling Machines, Drills, Parallel and Instantaneous Grip Vices, Screw Stocks, Taps and Dies, Saws, Wrenches, &c., &c., specially selected from the best American Manufacturers, therefore of the very highest quality, and at low prices. *Send for Illustrated Catalogue, 150 Illustrations, price 6d., post free.*

MODEL STEAM ENGINES, and Complete Sets of Castings of same, of every description, from the smallest to powerful Engines.

**LEE'S ILLUSTRATED CATALOGUE.**

New and Revised, Prices greatly Reduced. To Amateurs the most useful book extant, and largest and best Catalogue in the Trade. 64 pages, 110 Illustrations, price 6d., post free. Please state whether American Tool or Model Steam Engine Catalogue is required when ordering. ONLY ADDRESS— *76, 77, and 78a, HIGH HOLBORN, LONDON, W.C.*

Gateway entrance directly opposite the Inns of Court Hotel. Awarded Prize Medal International Inventions Exhibition, 1885. Please name this Paper when writing.

## PAINTERS!! GRAINERS!! DECORATORS!!

**The Art of Graining** is now complete, and contains 20 splendid plates. The finest example of graining ever published. Each plate is 18 x 13.

*Price in Parts, 36s. Bound, 42s.*

30 pages of Technical Instruction.

**Painted Wall Decoration.**

2/6 The Christmas Number of the Journal of Decorative Art. 2/6

A Perfect Manual of Design and Technical Instruction on

SURFACE DECORATION,

containing

10 LARGE SHEETS OF WORKING DESIGNS, BORDERS, DIAPERS, POWDERINGS, ETC. ETC.

(*Price 2s. 6d.; post free, 2s. 9d.*)

*For full particulars, see the November Number of* **The Journal of Decorative Art.** (7d.)

**W. G. SUTHERLAND,**

15, ST. ANN STREET, MANCHESTER.

**SIMPKIN, MARSHALL & CO., LTD.,**

317, STRAND, LONDON.

## THE NEW PATENT TRANSFER GRAINING PAPER,

As its name implies, transfers natural wood and marble veins to any painted surface, completely surpassing all hand work, on account of its *perfect* resemblance to the natural wood, and its highly artistic finish.

GRAINING!

To grain and varnish one yard takes five minutes; cost of material only 1d. Send **1s. 6d.** for sample yards of different Oak Grains, or **2s. 6d.** for sample roll and samples. See Article in this Paper of July 4th. Over 100 designs in wood and marble. Various shades and grains to select from.

**GEORGE ENGEL,**

**18, CASTLE STREET, FALCON SQUARE, LONDON, E.C.**

Use only the **PATENT Transfer Graining Paper.**

*BEWARE of useless, spurious imitations.*

COMFORT WARMTH & HEALTH IN WINTER

FOR **3/11**

We will supply you a very good Unshrinkable Flannel Shirt in pretty Greys and Fawns that will wear twice the length of time of any other shirt. Send size of neckband to **West Riding Flannel Co., Leeds.** Carriage Paid on two or more shirts. Write for patterns.

POST FREE ON APPLICATION.

# MECHANICS' OWN BOOK.

**A MANUAL FOR HANDICRAFTSMEN AND AMATEURS.**

SUMMARY OF CONTENTS:—Casting and Founding in Iron, Brass, and Bronze—Forging and Finishing—Sheet Metal Working—Soldering and Brazing—Carpentry and Joinery: embracing descriptions of 400 Woods; over 200 Illustrations of Tools and their Uses; Explanations, with Diagrams, of 116 Joints and Hinges; and examples of Construction of Workshop Appliances, Rough Furniture, Garden Erections, and House Building—Cabinet Making and Veneering—Carving and Fretwork—Picture Frame Making—Upholstery—Painting, Graining, and Marbling—Varnishing, Polishing, and Gilding—Mechanical Movements, illustrating Contrivances for transmitting Motion—Turning in Wood and Metals—Masonry, Brickwork, and Concrete—Plastering, Whitewashing, and Paperhanging—Bells and Gas-fitting—Lighting, Warming, and Ventilating—Roads and Bridges—Ditches and Drains—Water Supply and Sanitation—House Construction in New Countries.

**LONDON: E. & F. N. SPON, 125, STRAND.**

# A WONDERFUL MEDICINE.

# BEECHAM'S PILLS.

*Beecham's Pills* *Beecham's Pills* *Beecham's Pills* *Beecham's Pills* *Beecham's Pills* *Beecham's Pills* *Beecham's Pills* *Beecham's Pills* *Beecham's Pills* *Beecham's Pills* *Beecham's Pills* *Beecham's Pills* *Beecham's Pills* *Beecham's Pills*

ARE universally admitted to be worth a Guinea a Box for Bilious and Nervous Disorders, such as Wind and Pain in the Stomach, Sick Headache, Giddiness, Fulness and Swelling after Meals, Dizziness and Drowsiness, Cold Chills, Flushings of Heat, Loss of Appetite, Shortness of Breath, Costiveness, Scurvy and Blotches on the Skin, Disturbed Sleep, Frightful Dreams, and all Nervous and Trembling Sensations, &c. The first dose will give relief in twenty minutes. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

## WORTH A GUINEA A BOX.

For Females of all ages these Pills are invaluable, as a few doses of them carry off all humours, and bring about all that is required. No female should be without them. There is no medicine to be found equal to Beecham's Pills for removing any obstruction or irregularity of the system. If taken according to the directions given with each box, they will soon restore females of all ages to sound and robust health. This has been proved by thousands who have tried them, and found the benefits which are ensured by their use.

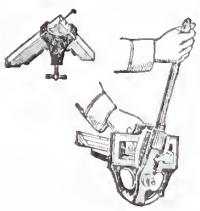
For a Weak Stomach, Impaired Digestion, and all Disorders of the Liver, they act like magic, and a few doses will be found to work wonders on the most important organs in the human machine. They strengthen the whole muscular system, restore the long-lost complexion, bring back the keen edge of appetite, and arouse into action with the rosebud of health the whole physical energy of the human frame. These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the Nervous and Debilitated is, BEECHAM'S PILLS *have the largest Sale of any Patent Medicine in the World.*

## Beecham's Magic Cough Pills.

As a Remedy for Coughs in general, Asthma, Bronchial Affections, Hoarseness, Shortness of Breath, Tightness and Oppression of the Chest, Wheezing, &c., these Pills stand unrivalled. They are the best ever offered to the public, and will speedily remove that sense of oppression and difficulty of breathing which nightly deprive the patient of rest. Let any person give BEECHAM'S COUGH PILLS a trial, and the most violent Cough will in a short time be removed.

Prepared only, and sold Wholesale and Retail, by the Proprietor, THOMAS BEECHAM, ST. HELEN'S, LANCASHIRE, in Boxes, 9½d., 1s. 1½d., and 2s. 9d. each.

Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*



## PROFITABLE HOME WORK.

With BOOTH BROTHERS' **Registered Mitre-Cutting Machine**, any person, without previous instruction or practice, can make a Picture Frame. This Machine is now largely used in the Trade, nearly 6,000 having been sold. Write for Illustrated Circular to the Sole Makers—

BOOTH BROTHERS,

Fig. 2.—End or Side Elevation, on same Scale.

A

DRAWING-ROOM

CABINET.

## A DRAWING-ROOM CABINET.

BY A. T. HARTINGTON.

INTRODUCTORY — SIMPLICITY OF CONSTRUCTION— MATERIALS — DIMENSIONS — ANALYSIS OF ARRANGEMENT OF LOWER PART—OF UPPER PART — GLASS — LINING CUPBOARDS— FULL-SIZED DETAILS.

THE cabinet is to the drawing-room what the sideboard is to the dining-room—the principal piece of furniture, or at any rate the most imposing in appearance. Originally, no doubt, the cabinet was a small portable cupboard, which, as it developed, was divided into separate compartments, more, perhaps, for utility than for ornament. Now the arrangement of the cupboards forms an important part, even so far as appearance only is concerned, and a cabinet may not inaptly be regarded as an assemblage of small cupboards.

The one which forms the present subject, as will be seen from the illustrations, Figs. 1 and 2, the former showing the front and the latter the end elevation, is admirably adapted for the display of those knick-knacks for the reception of which a cabinet is primarily intended. It also forms in itself a useful and handsome piece of furniture, which, if properly carried out, represents considerable monetary value. Possibly many readers may be inclined to think it too elaborate for them to construct, and very likely they are right, for it is just the kind of job which requires a fairly expert maker, as unless made well the result would not be so satisfactory as if something simpler had been attempted. At the same time, I may as well point out to those to whom the apparent complexity may possibly cause a degree of hesitation, or a doubt that they could manage to make the cabinet, that there is really no difficulty about it. If they can make any single part, say one of the cupboards, separately, they can do the lot. The construction is really very simple and not beyond the ability of any fairly competent cabinet-maker. He will require more time, but little, if any, more skill than if he were making a small two-door cabinet. Neatness and accuracy must be studied, and if he does so he may depend on turning out a presentable piece of furniture.

Now, without going into details which would be needless to those who can make this job, a few hints may be acceptable.

Originally designed for, and made up in, American walnut, with carved panels, as suggested, the cabinet is eminently suited for the fashionable rosewood, with marquetry substituted for the carvings, and inlaid stringings instead of the beads shown on the squares.

Figs. 1 and 2 are drawn to the scale of 1 in. = 1 ft., so that it will be seen that the principal measurements are as follows :— Width, 5 ft. ; height to top of lower part, 3 ft. 4 in., and overall, 8 ft.; depth from back to front, on top, 1 ft. 6 in., and 9 in. on the upper part, exclusive of the projection of the top moulding.

Analysing the design, the lower part is seen to consist of two end cupboards, with open space between them and the top ; in the centre a two-door cupboard, immediately under the top, and separated by an open space, with spindle-rail and turned column from the bottom cupboard, which is enclosed by a door hinged at the bottom and forming a convenient place for music or large books. The other cupboards have glass panels, either plain or silvered, as it may be desired to let the contents be visible or not.

The upper part, of course, is separate from the lower, and immediately above the top, in the back, are three silvered plates with bevelled edges—in fact, in a good job of this sort all the plates, whether transparent or silvered, ought to be bevelled. Above these plates are cupboards at each end, with a shelf on a line with their bottoms. Above this shelf, in the back, is a silvered plate, and immediately above it two small cupboards, with an open space between them, and with a glass at the back. Above the end cupboards the back, instead of being flat, is curved forwards to the top, or coved, the space between the coves being occupied by a glass at the back.

Other details will be seen more distinctly from the design, and few remarks about them will be necessary.

The end cupboards of the upper part are shown with transparent glass panels in the outer ends, and their backs should either be lined with velvet (plush) or with looking-glass. If a shelf is desirable inside, let it be of plate-glass with polished edges. The end cupboards of the lower part may be treated in the same way, but it is generally better to have the lower parts of cabinets, etc., more solid looking than the uppers. The principal details are given in the next page as follows :—

Fig. 3 shows one of the turned columns, all of which are the same in pattern, but vary in length according to their position. Above the turned part a sectional drawing gives the beading which is used on all the fronts of the squares, and by reference to Fig. 1 it will be noticed that they should be stopped.

Fig. 4 shows the moulding of the top, which the veriest tyro need hardly be told will be lined up, and not solid in the full thickness of the edge.

Fig. 5 gives a half-size representation of the moulding on top, together with its accompanying frieze. With regard to this a few remarks may be necessary. Above the coves it will be seen to be rounded and fluted as indicated in Fig. 5. As is, no doubt, well known to the majority of those who will make this cabinet, the rounded portion is simply planted on after having been turned in the lathe, and as four pieces will be required, two of them being in the lower portion above the end cupboards, they will be turned at the same time by being temporarily fastened on to a central block or core.

I do not think any practical cabinet-maker or joiner will experience any difficulty in carrying out the design, and, though I am not writing for novices or unskilled amateurs, if any of these intend to make the cabinet, and find there is some part of the construction which they do not understand, if they will state exactly where their difficulty lies I will endeavour to help them through "Shop." Vague requests, however, that they may be told how to make the cabinet, or any portion of it, will, however, hardly be worth noticing, so perhaps inquirers will please state just the points they want to know about.

It may be said that when it is completed the cabinet presents a splendid appearance, and will be found to be a handsome and comprehensive receptacle—if I may be permitted to use such a qualifying term in reference to the article of furniture now under consideration—for a fair percentage of the thousand and one things which collectors of bric-à-brac and curiosities generally delight to gather together, and with this I must quit my subject.

## SHORT LESSONS IN WOOD-WORKING FOR AMATEURS.

BY B. A. BAXTER.

### THE PLANE.

IN our second lesson we were introduced to the "winding strips" and their use ; we ought now to make the acquaintance of the trying plane. The jack plane, which we have hitherto used, does not give such accurate surfaces as the trying plane, because it is smaller, and also because it is not usually sharpened so carefully or its surface so well kept. The trying plane in general use is 22 in. long, the jack plane being usually 17 in. ; this shows that the trying plane is much superior in producing flat surfaces.

Having, by means of trying plane, winding sticks, and careful work, produced a flat surface, mark it ; for it is much less trouble to obtain true surfaces from the first than to employ winding sticks for each fresh surface ; therefore, whatever angle it is desired that the second surface shall have in relation to the first, it can be obtained by the use of a square or bevel, for if a surface is everywhere in the same relation to a flat surface, the second is also flat. When two adjacent surfaces are thus planed, and the angle correct, the other two surfaces are generally required to be parallel to the first planed. This is generally accomplished by using a marking gauge, and when the pupil can plane a piece of wood, the section of which, cut at right angles to two adjacent sides, gives four equal and therefore right angles, he will have achieved much in the way of mechanical manipulation.

There are other varieties of planes in constant use for special purposes, but enough has been said to suggest the fact that a plane is a copying tool : the iron cuts, and leaves the wood the counterpart of itself.

The next attempt in the use of the plane may be to try and plane the edges of two boards until they agree. This is difficult for a beginner, so I have said "attempt," but the effort cannot be anything but beneficial even if not quite a success. The material for this exercise may be two pine boards, 11 in. wide and 1 in. thick. They should be well supported in the bench screw and upon a bench pin in the sideboard, supporting the board at a convenient height ; from 3 ft. to 4 ft. will be a suitable length.

Another useful exercise in planing is to make a straight-edge or a plumb-rule. In doing this the use of the gauge is involved, but it has also this advantage : that it is a test for the performance of the trying plane. If the plane is slightly untrue, as sometimes will be the case, through violent changes of temperature or from continual use, the planing of an edge and the use of a gauge, followed by the use of the *same* plane in the *same condition*, will be a test of the state of the plane. Should it have been used for small work for some time the plane will probably have worn hollow, and will therefore make the edge of the board rounding, and all the efforts of the worker cannot make a straight edge ; on the other hand, if the plane has worn, as planes generally do, chiefly in front of the cutter, then the plane will be more prone to work "hollow," for the plane produces the counterpart of itself.

The beginner must not, however, attempt to correct his trying plane, but must obtain skilled help from a joiner or take his plane to a plane-maker, telling him what he considers to be the fault, and when it is returned, do not drive the wedge in so tightly as to strain the plane.

## HOW TO MAKE A QUARTER HORSE-POWER STEAM ENGINE.

BY F. A. M.

THE CROSSHEAD JOINT—CRANK-SHAFT—THE ECCENTRIC AND STRAP—THE ECCENTRIC AND VALVE-RODS.

FITTING CROSSHEAD JOINT—CENTRING AND TURNING THE CRANK-SHAFT—TURNING THE ECCENTRIC STRAP—CHUCKING AND TURNING THE ECCENTRIC—HOW TO TAKE UP WEAR IN THE BEARINGS—TURNING THE VALVE-ROD AND FITTING THE JOINT—PUTTING THE ENGINE TOGETHER AND ADJUSTING THE SLIDE-VALVE.

LET us now return to the crosshead and complete it. The first thing to do will be to file up the sides, or cheeks, of the upper part true with the hole, and bring it to 1 in. wide (see Fig. 8, page 328), so that it may fit between the sides of the fork of the connecting-rod. The little mandrel, *m*, of Fig. 53 (page 501), has been turned to the taper of the reamer used for cleaning out the hole for the crosshead pin; it will therefore fit into that hole projecting at both sides. Now, if on that mandrel we fit a little thick ferrule or annular disc of about 1 in. diameter, so that, while fitting on the mandrel, it can be brought up to touch one of the sides, it will form a guide for the filing just as the head of the crosshead pin did when we were working upon the fork of the connecting-rod. Take a bit of round iron or brass of about 1 in. diameter, and say 1 in. long, bore a $\frac{1}{4}$ in. hole through it, and try it on the small end of the mandrel, *m*, where it projects through the hole in the crosshead; if it will not go on, enlarge the hole in it with the reamer till it will go up into touch with the face of the crosshead; now take it off, drive out the little mandrel, and drive the little piece of iron on to it; put it thus in the lathe and square up both ends, or sides, of it; knock it off mandrel *m*, put mandrel into crosshead, and put the little piece on the projecting end, when it should fit the mandrel and come up into touch with the crosshead, so that you can use it to test the side of the crosshead and bring it true with the hole. The other side may be made parallel by means of the callipers, or the little ferrule may be bored a little larger with the reamer, so that it can be pushed further up mandrel *m*, and so be used upon the other side of the hole in the crosshead. The remainder of the crosshead may be filed up to look well, and the oil-hole at the top enlarged and tapped for the lubricator, when the crosshead may be oiled and laid aside.

Fig. 3.—Pattern for Turned Pilaster (half size).

We may now undertake the crank-shaft. A sketch of the forging supplied for this appears at Fig. 55. A round bar, 1 in. in diameter, is bent for the crank, and the flattened ends are turned up at A, A, to assist in the turning, which ends are afterwards cut off. The outer surfaces (*a b* and *c d*) may be roughly squared up first, and then the centres (*b* and *d*) found by placing the crank on the V's, marked with the centre-punch, square-centred in the lathe, and drilled up as usual for turning the crank-shaft, the arms, A, A, acting as carrier for the driver chuck. Next, a point-tool may be used to strike a circle on the ends of A, A, at *a* and *c*, just $2\frac{1}{8}$ in. from the centre of the shaft. When the arc is struck at *c* the tool would be withdrawn and the crank turned end for end, when it would be moved forward to strike an arc at *a* without otherwise disturbing it, so as to ensure the radius being exactly the same at each end. Do not on any account exceed the measurement of $2\frac{1}{8}$ in., or you will have to reduce the thickness of the piston or take other measures to prevent its knocking against one or both ends of the cylinder. The centres at *a* and *c* must be absolutely in the same plane as the centres *b* and *d*. To ensure this, try the forging on the surface-plate, and file the underside till it ceases to rock, and till the centres, *b* and *d*, both come opposite the point of the scribing-block. Now, with the point so set, scribe across the arcs previously marked at *a* and *c*; the points, *a*, *b*, *c*, *d*, will then be, all of them, equidistant from the surface-plate, and therefore they all lie in one plane. Countersink and drill the centres at *a* and *c*, and put the crank in the lathe to turn the main part of the shaft. Though the surfaces, *a b*, *c d*, are supposed to have been filed fairly square and true, yet it will be well, first, to turn them true in the lathe. The dimensions written on Fig. 55 are the forged dimensions, and give the size of the work before it is turned. In turning up the ends of the shaft and the arms, A, A, bring the extreme length to that written upon the drawing Fig. 5 (page 260), namely, $1\frac{3}{4}$ in. by 1 in. by $1\frac{1}{5}$ in. by $\frac{3}{4}$ in. by $1\frac{1}{8}$ in. by 1 in. by $1\frac{3}{4}$ in. = $8\frac{1}{2}$ in. When this is done, the end surfaces, *a b* and *c d*, will be used to measure from, and this will help us to get the necks for the two bearings, and that on the crank-pin, correctly placed. We may now proceed to turn the shaft on the centres, *b*, *d*. If the crank were weaker we should have to fit a bit of hard wood between the throws, or arms, of the crank; but this will hardly be required in the present case, except in square centring. Turn the main part at each end to $\frac{7}{8}$ in. full, leaving a little to come off at the final finishing, when the arms, A, A, shall have been cut off, and when the eccentric and fly-wheel are being fitted; turn the necks for the bearings, taking out the brasses and trying one of each pair upon the neck which is to turn in it, as it is quite essential the fit should be good, both as to diameter and as to the rounding of the corners. It is comparatively easy to make a fit when you can use one of the brasses as a gauge for your work as you turn the neck; whilst, if the shaft had been made first, it would have been very difficult. Take care to get the necks as smooth and round as possible, and well polished, then rub them over with marking, and rub the brasses round on them, to see whether they bear evenly; you may very likely find a little scraping necessary inside the brasses to make them fit perfectly. Having finished the main bearing necks, place the lathe centres at *a* and *c*, and turn the neck of the crank-pin in a similar way, trying the brasses of the connecting-rod upon it as before described. The crank-pin being thus finished, the arms, A, A, may be cut off with the hack-saw, the ends of the shaft turned, and, if desired, the arms or throws of the crank can be filed up and polished; or that part may be painted. The fly-wheel is supposed to be already finished, and to have a keyway cut in it $\frac{3}{8}$ in. wide and $\frac{3}{16}$ in. deep. The key should be of steel, as also that for the eccentric, which, however, need not be more than $\frac{5}{16}$ in. wide and $\frac{1}{8}$ in. thick. It would, of course, be more orthodox to sink a groove in the shaft instead of simply filing a flat as shown at Fig. 16 (p. 328); but this would require a slot-drill, and, by making the key for the fly-wheel rather wider than usual, it will hold the fly-wheel firmly if well fitted; the profile of the key for the eccentric is shown at Fig. 19 (p. 328). It and the larger one for the fly-wheel are about $\frac{1}{64}$ in. thinner at the point, so as to cause them to tighten up like a wedge, the bottom of the keyways being carefully filed to the same slope so that the key may bear equally hard all along its length. The fly-wheel

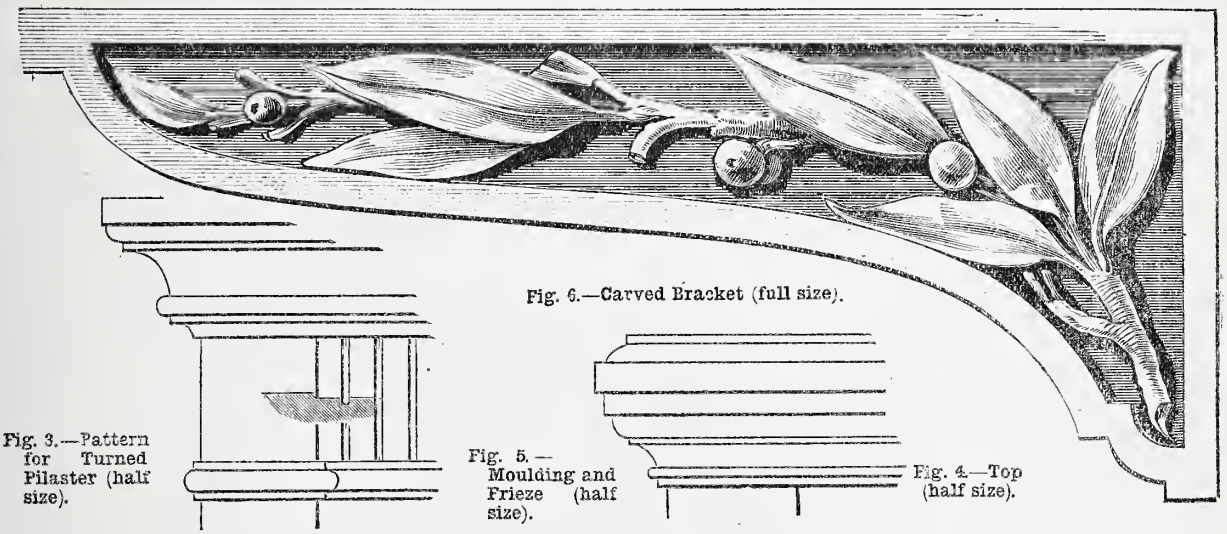

Fig. 6.—Carved Bracket (full size).

Fig. 5.—Moulding and Frieze (half size).

Fig. 4.—Top (half size).

being bored, we may at once finish one end of the crank-shaft, and make it fit accurately into the wheel; it may then be laid aside till the eccentric is finished, since it is easier to fit a shaft to a hole than *vice versâ*.

*Eccentric and Strap.*—The eccentric and its strap may next be undertaken; they are shown in Figs. 16, 18, and 19, as well as in the complete views. The eccentric for the feed-pump is so arranged that it may be added or left out, according as it is required to have a feed-pump or not; it is shown, with its method of attachment, in Figs. 19, 20, and 21: it is simply bored out to fit upon the boss of the slide-valve eccentric, and fixed to it with two screws. Taking in hand the eccentric strap first, file up the ears, where the screws pass through, to fasten the two halves of the strap together. These four surfaces should be got up with the help of the face-plate, using a square to try whether the half strap stands up straight on the plate; the ears are $\frac{3}{8}$ in. thick. When, therefore, the four little surfaces have been filed true, set the point of the scribing-block to $\frac{3}{8}$ in. high, and, holding the half straps in one hand, scribe across the ears of both, on each side, a line $\frac{3}{8}$ in. above each of the four finished surfaces so as to mark the thickness of the ears, then file to these marks so as to get a flat surface for the heads of the screws. Next set the scriber point to $1\frac{5}{8}$ in., and mark off the large flat surface on the one half strap and the small one on the other. Tin the ears and solder the two halves of the strap together, then fit the screws and screw them firmly in. Now file one side of the strap, thus united, perfectly flat; screw a piece of hard wood on to the face-plate, chuck, and turn it true and flat; lay the flat side of the strap upon this and fix it by means of two dogs, in a similar way to that shown at Fig. 36, the dogs clasping only about $\frac{1}{8}$ in. of the ears, so that almost the whole of the front surface of the strap can be turned true; face up this front surface, bringing the strap to $\frac{1}{2}$ in. thick, and turn out the interior, observing carefully the dimensions in Fig. 18; scratch a fine line round, to which you can file the outside, and take the strap from the lathe to finish with the file. You can then chuck it again the reverse way to smooth and polish the first side, then melt the solder and separate the two halves. Now take the eccentric itself, grasp it in a universal chuck by the boss, bore the hole $\frac{7}{8}$ in., and cut or mark the key-way; fit it on to a mandrel (the crank-shaft would do, but mind it does not get bent when you hammer it on and off)—it must fit rather tight—put it between the centres, and finish the outside of the boss and the sides of the eccentric, bringing it to $\frac{1}{2}$ in. wide. To turn the outside of the eccentric we need a die chuck, but, failing that, can manage another way. Put on the face-plate chuck, with a flat piece of hard wood upon it, truly faced up; prepare another piece of hard wood $1\frac{1}{8}$ in. thick, or more, and about 5 in. by 4 in., with edges nicely squared up; put two long screws through the corners of this and screw it upon the middle of the first piece, sinking the heads of the screws below the surface, so that you can face it up in the lathe; now bore in the lathe a $1\frac{1}{2}$ in. hole in the centre of this piece, 1 in. or more deep, into which you can press the boss of the eccentric; the radius of the eccentric which joins its two centres must be placed parallel with two sides of the squared-up piece. Fig. 56 will make this plain: A is the face-plate; B, the first piece of wood; C, the second, in which the boss of the eccentric is fitted, the eccentric standing up on a line, *a b*, parallel with lines *c d*, *e f*, drawn on B. Now it is evident the two screws holding C to B may be taken out, and the piece C moved down $\frac{1}{2}$ in. along the lines *c d*, *e f*, and refixed there; thus the piece C acts like the slide of an eccentric chuck, and enables us to bring the sheaf of the eccentric true with the centre of revolution of the lathe, so that the outside of the eccentric can be turned. Lest the eccentric should move while being turned, owing to the boss turning round in the hole in C, an iron clamp, *g*, may be placed across the hole and secured by a screw passing through that hole into the wood. The half of the eccentric strap will, of course, be used to test the work, and the eccentric should be made to fit, both on the $\frac{1}{4}$ in. middle band, and on the smaller $\frac{1}{8}$ in. bands on each side of it, so that the eccentric may bear upon the whole $\frac{1}{2}$ in. width of the strap, an advantage this form of construction has over the older arrangement, where the strap works in a groove in the eccentric, which latter must then be the widest and, therefore, must take up more room on the shaft. When the straps wear, as they must do in time, as also the brasses of the connecting-rod, etc., they must be taken apart, and a little filed or scraped off the ears where the straps are screwed together, or off the brasses where they touch, until all looseness is gone and the fit is again perfect. If this is not done the engine will "knock" on each "dead centre"—that is, there will be a thump heard every time the piston changes its direction of motion. Whenever such a thing happens the cause should be sought for, and the noise stopped. An engine in proper order makes no knock or thump; the slightest noise of that kind suggests bad workmanship. Our engine should be quite inaudible in the next room; no one need object to have it in a room in the house if the workshop be so situated; its presence will not be suspected if it be kept in proper order.

The eccentric-rod and the valve-rod would seem to come next in order. A casting is provided for both. The valve-rod will require to be turned up, and draw-filed like the piston-rod, to avoid wearing out the stuffing; but, as it is only $\frac{3}{16}$ in. in diameter, it will require some kind of a back-stay to support it whilst being turned. When the shaft is finished to size the thread may be cut with stock and dies, taking care not to cut it too high up, so that the threaded part will be drawn into the stuffing-box. Then the nuts may be threaded in a three-jawed universal chuck, and trued up in position on the rod.

The joint is the only remaining point which need delay us. File up first that part which belongs to the valve-rod. It requires to be $\frac{1}{4}$ in. thick; and the flat surfaces on each side to be parallel with the centre line of the rod, and equally distant from it. These conditions can be simply ensured by pressing one of the surfaces down upon the surface-plate, so that the length of the rod is supported in the air, when it will be easy to see whether it is parallel with the plate or not.

When this part is satisfactory file up one side of the joint on the eccentric-rod, taking care that it is parallel with the length of the rod, and "out of wind" with the flange at the large end; then file the other three surfaces of the joint to this first one, as before described for the fork of the connecting-rod. Bore both parts of the joint with a $\frac{1}{4}$ in. drill, put them together, clean out the hole with a $\frac{1}{4}$ in. reamer, and turn the pin of cast steel to fit. Then harden both parts of the joint with prussiate of potash, harden the pin, and grind it in with emery powder. Clean off the emery, and the joint is finished.

No directions appear to be needed for fitting the flange at the larger end to the eccentric-sheaf; and the eccentric-rod itself may be got up bright, draw-filed, and finished with emery-cloth, or it may be simply left rough and painted.

*Putting together the Engine.*—It will be well at this stage to fit the parts, thus far finished, together.

The cylinder being bolted to the bed-plate, the piston and rod in place, the crosshead and guide plates fixed, put the crank-shaft into the two bearings, and put the connecting-rod on to the crank-pin, and, after laying these parts on the bed-plate, bring together the fork end of the connecting-rod and the crosshead, passing the pin through, and securing the joint. Push the piston to the bottom of its stroke, as it appears in Fig. 5; place the crank horizontal, and mark on the bed the position occupied by the soles of the two crank-shaft bearings. Now turn the crank half-round, pulling out the piston to the end of its stroke. Set the crank again horizontal, and mark again the position of the soles of the bearings on the bed-plate. This position should be the same as before, but if the bearings have moved a little in the direction of the length of the bed, you have only to place them in an intermediate position, so as to split the difference; scribe through the bolt-holes in the feet of the bearings on to the bed, drill and tap these holes, fix the four studs, and bolt the bearings down on the bed.

The brasses of the large end of the connecting-rod having been clasped on, the crank-pin should suffice to place the crank-shaft fairly at right angles with the centre line of the engine. Any error that might arise would be eliminated by splitting the difference between two positions. The studs which secure the bearings should fit fairly well in the holes, so as to act partly as steady pins.

Now you may as well file a flat on the crank-shaft, and make the key to secure the fly-wheel. Fit this carefully, and drive it in pretty firmly, and you can then turn the engine round by the wheel. Try it round to see whether it moves evenly, or whether it sticks or moves stiffly at any point. If it does, seek what is wrong by taking off one thing after another, till you find what is tight.

For instance, you might disconnect the crosshead joint, and try the three brasses on the crank-shaft alone. Suppose there is still a tightness, then you could loosen them one by one, then tighten one at a time, turning the wheel every now and then.

Your aim should be to have the bearings all equally tight, so that the shaft can freely revolve without much friction, and yet without being loose enough to knock. However, there is sure to be a slight stiffness in a new engine, which will wear off by-and-by.

We could prevent this by grinding in the joints, but if we did so there would probably remain in the bearings a little of the sand, which would cause them to wear away continually, so that it is a dangerous thing to advise. A shaft may be ground in with emery if, like the mandrel of a lathe, both it and the collar, or bearing, are left "dead" hard—because emery powder cannot get embedded in hard steel. A joint or bearing of iron or brass would be ruined if ground together with emery, because the emery could never be got out again. A

joint of brass or iron can be ground together with the grit from the grindstone trough, if, like the plug of a tap, it is only moved occasionally; but if, like the bearings of our engine, the shaft is to turn continuously, it is better to trust to scraping out the brasses where they seem to bind, and to keep all abrasive powders far away.

Having now, thus far, put together or erected the main parts of our engine, we will proceed to adjust the slide-valve. Pass the valve-box over the studs, and, leaving off the cover for the present, put in the slide-valve, and pass the valve-rod in through its stuffing-box; two nuts, slide-valve, and two more nuts, locking these in pairs on each side of the valve. Now connect the eccentric-rod with the valve-rod and with the eccentric, this latter being in its place on the shaft, but not keyed—the keyway being cut in it, and fitted with a temporary key bearing upon the round shaft, on which the flat has not yet been filed. Place the piston in the position shown in Fig. 5, the crank being horizontal, and the piston at the end of its stroke. Now turn the eccentric round upon the shaft till it points upwards, and away from the cylinder, in the position shown at Fig. 16, making an angle of about 120° with the crank. The valve should now be just beginning to uncover the port leading to the bottom of the cylinder, as it is seen in Fig. 5.

If this is not the position of the valve, that will be owing to one of two causes: either the angle of the eccentric is not correct, or the length of the connection between the eccentric and the edge of the valve is not exact. Turn the eccentric on the shaft till the valve uncovers the edge of the port, so that you can get in the corner of a visiting card. That distance is called the lead of the valve, as explained in the introduction. Fix the eccentric by the temporary wedge, and turn the crank just half-way round, till it stands level, whilst the piston is at the opposite end of the stroke. Now, the valve, to occupy the proper position, should be uncovering the other port by the same distance, and then we should say the lead was equalised; this, however, is not likely to be the case till the length of the eccentric-rod, etc., has been adjusted.

Let us suppose the valve, instead of having only just opened the port, has opened it by half its width—*i.e.*, it has moved too far by ⅛ in. This would prove the eccentric and valve-rods were too long by half that distance. Now, we can shorten the effective length of the valve-rod by moving the nuts. Move these nuts, then, so as to diminish the excessive travel of the valve by one-half of ⅛ in., so that, without moving the other parts, the valve shall be open but one-quarter of the width of the port. Now loosen the wedge of the eccentric, and turn it round on the shaft till the valve is open by the thickness of a card, fix the eccentric by the wedge, turn the crank round to the first position, and observe the valve, when we should find the lead is about right. Enough has now been said to show how the lead can be equalised, and the proper angular position for the eccentric found. When this has been determined, mark on the shaft the position of the keyway of the eccentric, and take off the eccentric to file the flat on the shaft for the permanent key. When the key is being finally fitted test the lead again, to make sure you have the flat filed just right: it is easy to adjust with a flat on the shaft, a thing that cannot be done with a sunk keyway.

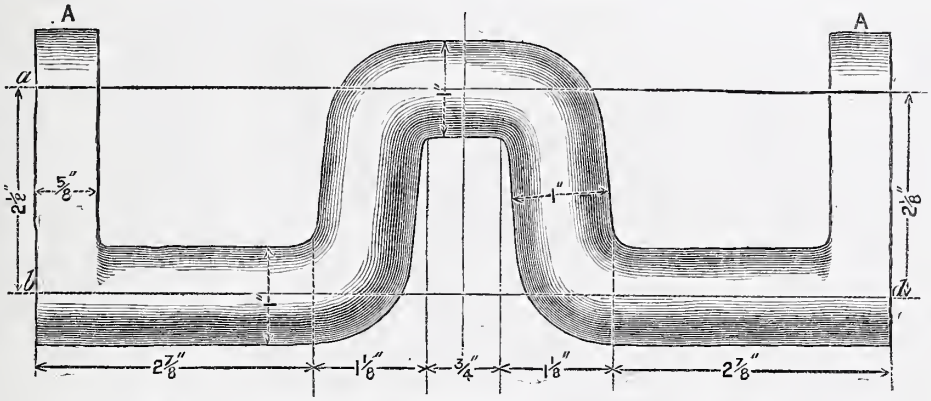

Fig. 55.—Sketch of Forging for Crank, with Dimensions of Forging.

## A FEW PHOTOGRAPHIC EXPEDIENTS.

BY AN OLD HAND.

When almost everybody, gentle and simple, turns or tries to turn photographer, there are necessarily some to whom the good things of this life have been meted out with a sparing hand, and to such a few hints of how to make most of a little will perhaps be acceptable. There are two things without which it is impossible to take a photograph satisfactorily. A cigar-box and a pin-hole is all very well for those of the impressionist school, but for real practical work there is a *necessity* for a *camera* and *lens*. Although the cost of these articles has, during the last few years, been marvellously reduced, still, if the would-be photographer has to buy them, and requires good things of the kind—things that will bear some wear and tear—he must put down a certain amount of cash, that may not at all times be conveniently found. I would advise such to try and manufacture their own lenses and cameras—not so difficult a matter as appears at first sight. An article, or rather a series of articles were published in early numbers of Work, giving directions how to make a camera of a thoroughly good pattern at a much less cost than it would be possible to purchase one of a similar kind. A rough substitute for a camera could, of course, be knocked up with hammer, nails, wood, and bookbinder's cloth, but such are not worth the labour bestowed upon them. The failing of almost all cheap apparatus is its liability to get out of order and the wearing out of important parts. It is better by far to have an old pattern well-made thing than a common modern one with all its multifarious movements—that is, supposing one is purchased, but my advice is make them yourself. Now about lenses. In the spring of this year a Mr. Lionel Clarke read a paper at the Camera Club, giving the results of his experiments with *spectacle lenses*. This paper was published in most of the photograph literature at the time, and it is to this I would call special attention. A long time prior to this I had made use of this device in an emergency, and can fully bear out most of Mr. Clarke's assertions, and go yet further by attributing better qualities to such lenses than he felt inclined to concede. The first question is, What sort of spectacle lenses are to be used? as they vary so much in kind and quality. The answer is: get lenses of the periscopic form—that is, convex on one side and concave on the other, the curves on each side being different, the inside curve following the lines of a large circle, and the curve of the convex, or outside, that of a smaller one; the proportion of these curves to each other determine the focal length of the lens. Spectacle lenses of this form are generally used for old sight, and vary in focus considerably. They can be purchased separately at a lens dealer's, at a price from threepence each for ordinary glass and about fifteenpence for one made of pebble; the gradations of focus are, I believe, by two inches—26, 24, 22, etc. Now, for photographic purposes the use of these lenses singly is not altogether convenient. In the first place, the lines of the image are not straight, and the area of good definition is small compared with the length of focus; we therefore adopt the plan of placing two together, with the concave or hollow sides towards each other, with a very small stop between them. The small amount of light passing through such an opening makes it difficult to focus with unless on a very strongly illuminated subject; therefore, for convenience to the amateur in making such a lens, the stop may be placed close in front touching the lens. The focussing and arrangement of the subject may be done without the stop, which can be inserted afterwards. There will be only a very small portion, if any, of the picture absolutely sharp without the stop, but it will be remedied by its insertion. There are two kinds of foci in uncorrected lenses, called the optical and visual. The optical one is the one that forms the image on the sensitive plate, and the visual one is the one we see on the focussing screen in properly corrected lenses, such as the best sold for photographic work. These two foci are made to fall on the same plane, consequently, if the image looks sharp it photographs sharp; but with spectacle lenses it is not so, and this peculiarity has to be taken.

into consideration. The optical focus, the one we want, is about a fortieth of the length of the focus of the lens *shorter* than the visual, which means that with a combination of lenses having a focus of ten inches, the plate will have to be just a quarter of an inch *nearer* the lens than the distance that gives the sharpest image on the focussing screen, therefore in focussing prepare for a distant object in preference to one in the foreground. Knowing this much, we will put a lens together suitable for a picture whole-plate size, or less. First of all there is the tube or lens mount. Very often an old discarded tube may be had at the dealers in, or repairers of, photographic lenses. If this cannot be had, two short pieces of brass tube about an inch long and three-quarters of an inch in diameter will answer the purpose; a flat ring to act as a flange, with a thread turned on the inside suited to threads turned on the ends of the tubes, will be required to fix the lens to the camera. We now procure a couple of the periscopic spectacle lenses, made of pebble by preference, as the surface is harder and better in all respects than glass of twenty-four inches focus. Fasten them together, hollow sides inwards, with a little gummed paper round the edges; they must be exactly centred by placing the edges accurately together. Now make a disc of cork to fit accurately into the brass tube with a round hole in the centre, half an inch in diameter, in which the lens is to be fixed; the oval shape of the lens may be reduced by cutting it with a diamond and chipping off with a pair of good pliers; at any rate, the lens must be fixed upright in the tube—that is, at right angles with its sides—so that a stop made of thin metal, the aperture to be $\frac{1}{16}$ in., can be put in close contact with the glass; and in front of it another stop, with an aperture of $\frac{1}{32}$ in., will sometimes be useful. Any other means may be devised to fix the lens in position; so long as it is in the right position, the means by which it is done is immaterial. It will be found that when two lenses of equal foci are placed together the focus will be reduced by half—that is, the 24 in. will become 12 in.; add another lens of 24 in., and the focus will be reduced to 6 in. The focus will always be found to be nearly half that of the shortest focus, whether formed by a combination of lenses or single lenses. In the combination just referred to—two 24 in. to make a 12 in.—this forms a moderate angle view on a whole plate, and comes well to the corners. If we take a 24 in. lens and fix to it one, say, of 16 in., we have a much wider angle lens of a shorter focus; the variety of foci differs with every different lens used, and it is easy to make a combination to suit the purpose for which it is required, bearing in mind the longer focus lens should be the outside lens, and that the position of the stop not only regulates *the definition* but the size of the image. The more in front the stop is placed—that is, the further from the lens or front—the smaller the *area* of the image, and *vice versâ*. This indicates that a stop *between* the two lenses is the best place for it, as there we get a maximum of area and of definition. It may be thought that with such small stops the time of exposure would be enormously prolonged; it is not so, however, as compensation is afforded by the very trifling absorption of light of the thin media through which it passes. The lens just described would take a thoroughly exposed picture in an average light with the $\frac{1}{16}$ in. stop in five seconds, which is not abuormally long, with plates like the Ilford ordinary. With very rapid plates and a suitable sea-side subject the exposure, in spite of the small aperture, would be instantaneous. At any rate, I have said enough to enable anyone of constructive ability to make a thoroughly good working lens that will take pictures equal to the most expensive kinds, and at an exceedingly small outlay.

## THE WINTER ELECTRICAL MACHINE AND ACCESSORY APPARATUS.

BY CHAS. A. PARKER.

PREPARATION OF MACHINE FOR WORKING—ELECTRICAL AMALGAM—LEYDEN JAR—DISCHARGING ROD — DIRECTOR — JOINTED DISCHARGER — LEYDEN BATTERY—DIAMOND-SPOTTED JAR—SPORTSMAN JAR — LANE'S DISCHARGING ELECTROMETER—SPIDER JAR.

BEFORE passing on to the consideration of other accessory pieces of apparatus, a few hints with regard to the proper management of the Winter machine will doubtless prove acceptable to the majority of our readers. Owing to the fact that frictional experiments are usually performed in the winter-time as a means of amusement aud instruction for the young people during the long evenings, it becomes necessary to exercise the greatest possible care to prevent the condensation of moisture upon the apparatus, which is extremely liable to occur at this time of the year, for, if everything is not perfectly dry, it will be impossible to obtain uniformly good results.

Bearing the above in mind, it will be found advisable to thoroughly warm the machine previous to turning the handle, as any moisture conveyed by the plate to the rubbers will materially affect the results obtained. For this reason the machine should be placed at some little distance from the fire before it is put into action, as this precaution will have the effect of disseminating any moisture which would otherwise form on the plate. It is also necessary to carefully wipe the machine each time before it is put into use, as electricity, by virtue of its attractive power, collects innumerable particles of dust from the surrounding air, which act like so many points on the plate being revolved, and thus assist to dissipate the electricity as fast as it is generated. The electricity may be developed to a much greater extent if a small quantity of electrical amalgam is spread over the face of the rubbers.

*Electrical Amalgam* is a mixture composed of mercury, tin, and zinc, and can be obtained from any electrician, ready for use, at about 6d. per ounce, or, if preferred, it may be readily made in the following manner by the student himself: Melt together five parts of zinc and three parts of tin, and then pour nine parts of heated mercury on to the melted mass, and stir the whole together thoroughly. It is now poured into an iron or wooden box, and shaken up well until quite cold, when it should be collected and reduced to a fine powder, after which it may be placed aside in a convenient box or wide-mouthed bottle ready for future use. A small portion of the powder should be mixed up with lard in the form of a thick paste as required, and then smeared over the face of the rubber by means of an old knife. No more lard should be employed than is absolutely necessary in order to make it adhere. When it is wished to remove the rubbers from the holder, the plate should be given a few turns in the wrong direction, which will cause them to come out readily. A thin, even coat of amalgam may then be spread on the face of each one, after which they are returned to the holder.

To do this, hold them in position, one on either side of the plate, with the springs pressed down, and then push them forward with the plate until they are in the holder.

If the handle of the machine is now turned with a uniformly steady motion, the positive electricity will be driven over the surface of the prime conductor, from whence it may be drawn in the form of a bright spark; but, assuming the rubber and the prime conductor to be in their present insulated condition, the sparks will gradually become weaker and weaker, until at last they will cease altogether when the electricity of the plate has become exhausted.

In order to secure a continuous supply of electricity, it becomes necessary to connect the rubber with the earth by means of a length of chain attached to the nearest gas- or water-pipe. A suitable length of Dutch clock chain will be found to answer admirably for this purpose. Chain of this description, having small links the size and shape of Fig. 19, can be obtained from any watch and clock tool warehouse at about 3d. per yard; or, if preferred, the rubber can be connected with the earth by means of spirals of thick copper wire. When the machine is in use, it should be located on a table, quite clear of surrounding objects, as these will only tend to weaken the discharge by imperceptibly drawing off the electricity. It will also be found an advantage to clamp the machine firmly to the table, as it will then allow the student to work with greater freedom. It is a distinct disadvantage to work the machine at an express rate of speed, as the best results are obtained when a steady, uniform motion is maintained. With proper and careful management it will be possible to take 6 in. sparks from the small ball of the prime conductor when the Winter ring is attached to the machine, but the length of spark will be considerably lessened if it is drawn from the large ball of the conductor itself, owing to the fact that the tension is always greater at projecting portions than at approximately flat surfaces. After use, the rubbers may with advantage be removed and wrapped up and put away, the machine also being covered over. This precaution will have the effect of preventing any very great accumulation of dust, and will leave the machine ready for use when required.

*The Leyden Jar*, which is illustrated in Fig. 20, may be said to be one of the principal pieces of apparatus used in conjunction with an electrical machine. It takes the form of a thin glass jar or wide-mouthed bottle, which is lined inside and out with tinfoil, and provided with a wooden cap, through which a metal stem passes into the interior of the jar for the purpose of charging it with electricity. The lower end of this metal stem is furnished with a few inches of chain or a strip of thin sheet-brass, in order to make contact with the inner coating, and the upper portion terminates in a knob outside the jar, for, without this precaution, the electricity would be liable to escape from the end of the rod. The Leyden jar can, of course, be made to any size desired, but for all ordinary purposes a jar measuring about 12 in. in height and 8 in. in diameter will be found a useful size, sufficient for all ordinary purposes. Select a perfectly sound glass jar, entirely free from all cracks or imperfections, then proceed to coat the interior with tinfoil cut into strips about a couple of inches wide and of a suitable length to reach from the

bottom of the jar to within 2 in. from the top. The pasted strips of foil must be carefully introduced into the jar, and then made to adhere to the side by means of a small mop, which can be readily made by tying a piece of wadding on to the end of a strip of wood. Each succeeding piece of foil should be made to slightly overlap the preceding one, until the entire surface inside the jar has been completely covered, when a circular disc of foil a trifle smaller than the inside of the jar is cut and pasted over the bottom, thus completing the arrangements of the interior. For the outer coating, a single strip of foil of suitable size should be pasted and wrapped completely round the outside, with the edges slightly overlapping, not omitting to turn a narrow margin underneath at the base, after which the coating is completed by a suitable-sized disc of foil pasted on to the bottom. It is highly important for the outer covering to be laid on perfectly smooth and entirely free from creases or wrinkles, as, being open to inspection, any slipshod details will show with damaging effect. It is almost needless to say the two coatings should be of a uniform height.

For the rod we shall require a piece of stout brass rod, about ⅛ in. thick and a third longer than the total height of the jar. A narrow strip of thin sheet-brass, a trifle longer than the width of the jar, is now bent to the form of A, Fig. 21, and afterwards drilled through the centre, and then fitted and soldered on to the end of the rod, after which the latter is made to fit tightly into a hole bored through the centre of an ornamental lid or cap (B, Fig. 21), which is turned to a suitable size proportionate to the jar. Four small slips of cork, glued round the under edge of this wooden cap, will ensure the latter fitting tightly to the mouth of the jar. The cover, which should be turned from a piece of thoroughly dry mahogany, will require to receive two or three coats of good shellac varnish for the purpose of better insulation. An ordinary brass stool ball of suitable size will be found to answer very well for the knob of the jar. These balls, which can be obtained from any ironmonger, are provided with short screw stems soldered to the inside of the ball. It will be found a simple matter to heat the ball over a gas flame and melt out the screw, and then solder it to the end of the rod, thus forming the knob of the jar. After the stem and knob have been carefully lacquered, the brass spring should be pressed together slightly, in order that it may just pass through the neck of the jar; then the rod is steadily pushed downwards until it touches the bottom, when the strip of brass will adapt itself to the form of the jar, and thus ensure metallic contact with the inner coating of foil. A great many jam manufacturers are now using wide-mouthed jars made of hard, white glass of good quality, similar in shape to Fig. 20, which are admirably suited for use as Leyden jars, as the mouths are almost the width of the jar itself, which thus renders the attachment of the inner coating a very simple matter. The writer has seen these jars in two sizes, of ½ lb. and 1 lb. capacity, measuring outside 4 in. by 3 in., and 5½ in. by 3½ in., respectively.

*A Discharging Rod* is a very useful appliance, which is used for the purpose of discharging a Leyden jar when it is undesirable for the experimentalist to receive the shock himself. The discharger takes the form of a stout piece of brass wire about 12 in. long, which is bent in the form indicated in Fig. 22, and then inserted in a 1 in. length of brass tube ⅜ in. in diameter, to which it is secured by means of soft solder. Two small brass balls are now soft soldered to the ends of the brass arms, after which the central socket is cemented on to the end of a 6 in. length of ½ in. glass rod, which forms the handle. The width apart of the arms can be regulated to suit requirements by bending each one to the form desired. The piece of glass required for the handle may be broken from a larger rod, if a slight groove is first made round the rod by means of a file, after which the lower end should be rounded off on a grindstone. Another plan of making this discharger is to cement a small brass gas cap on to the end of the glass rod, and then insert the wire in a couple of holes of suitable size drilled through the cap on opposite sides as shown in Fig. 23.

*A Director* (shown in Fig. 24) is another form of discharger, which will be found very useful when discharging a Leyden battery and in manipulating various other pieces of apparatus. It consists of a 6 in. length of stout brass rod, which is soldered into a hole drilled in the end of a small brass gas-tap, and then cemented on to a 6 in. length of glass rod, after which the outer end of the brass rod should be bent in the form of a curve, and provided with a small brass knob.

*The Jointed Discharger* (illustrated in Figs. 25 and 26) will be found much more useful for all ordinary purposes than either of the foregoing, as the width of the arms can be accurately adjusted to the purpose for which they are required. A couple of pieces of stout brass rod should be softened in a gas flame, and then bent in the form of a loop at one end, which is afterwards flattened out on an anvil in order to spread the metal as much as possible. Thus prepared, the two arms are placed together, with a small washer in position on either side, in order that they may be joined together by means of a small brass nail passed through a central hole in the washer, and then riveted up tight, so that the arms may move stiffly. A couple of brass gas caps, ¾ in. diameter, are now procured from a gas-fitter, and provided with a couple of holes, which are drilled across the diameter of each cap near to the closed end. When this has been done, each cap is tightly fitted on to one of the jointed arms, and then soldered in position at about an inch from the joint. A couple of 4 in. lengths of glass rod of suitable diameter are now cemented into these caps, thus forming the insulating handles by which the discharger is held—a small brass ball being lastly soldered on to the end of each arm.

*The Leyden Battery* (which is shown in Fig. 27) will be found indispensable for the performance of certain experiments—when it is desirable to pass a powerful discharge through a body, or for the purpose of fusing or igniting various substances. The Leyden battery is formed by connecting the internal and external coatings of four or more jars, in order to render it possible to pass the full discharge from all the jars at the same instant. A wooden box of sufficient size to hold the jars, and about 2 in less than the total height of one of the latter, is provided with four supporting feet, and then French polished or varnished outside, after which the interior is carefully coated with tinfoil, and a brass drop handle is lastly screwed on to either end. Thus prepared, the jars may be placed in the box as required, the knobs which represent the inner coatings being connected together by means of a piece of brass chain, which is twisted round each jar. The Leyden battery is charged and discharged in precisely the same manner as a single jar. The inner coatings are put in communication with the prime conductor by means of a suitable length of chain brought from the knobs of the jars and hooked on to the latter, and the necessary earth contact is obtained by suspending a short length of chain from one of the handles. These handles, by the way, should be in metallic contact with the inner tinfoil coating of the box. This arrangement of Leyden battery will be found very useful when the jars are frequently used singly; but, supposing that several jars are kept solely for use as a battery, it will be found a good plan to connect the inner coatings together by means of cross rods of stout brass wire, which are sprung into holes drilled for their reception in the knobs of all the jars, as will be seen by reference to the cut.

*The Diamond-spotted Jar* (illustrated in Fig. 28) forms a very beautiful experiment when the discharge is viewed in a darkened room. The tinfoil with which the jar is covered is cut in the shape of small 1 in. squares, pierced with a central opening about ½ in. in diameter. Each piece of foil should be punched separately, whilst supported on a block of hard wood, using a ½ in. cork borer for the purpose. When a sufficient number of pieces of foil have been prepared, it will be time to begin coating the jar, commencing with the lower conducting surface. For this, first lay a disc of foil of suitable size over the bottom on the inside, and then paste a ¾ in. strip of foil round the sides and in contact with the disc covering the bottom. Thus prepared, the small discs of foil are carefully pasted on to the glass with the diagonals of the squares horizontal and vertical, and arranged in such a manner that the points nearly touch one another, as shown in Fig. 29, which is an enlarged detail of the coating, the shaded discs representing the inner coating. When a sufficient height for the coating has been reached, another narrow strip of foil should be pasted all round the top, after which the outside of the jar is coated in a precisely similar manner—a narrow strip of foil being pasted at the top and bottom in a corresponding position to the strips on the inside, with a circular disc of foil covering the bottom of the jar. The points of the outer discs of foil should be so arranged as to nearly touch each other in the centre of the opening of the inside pieces. By this means the sparks will be seen to simultaneously illuminate both the inside and outside on the jar being discharged. When the jar has been coated in a satisfactory manner, it should be furnished with a sound, dry, wooden cover, which is then varnished and fitted with a brass stem and ball in the manner before described. On the jar being charged, bright little sparks will be observed scintillating all over the surface when viewed in a darkened room; and when the discharge takes place, a beautiful bright spark will appear at the same instant at each angle over the entire surface.

*The Sportsman Jar* (which is shown in Fig. 30) forms a very amusing and interesting piece of apparatus, which is by no means difficult to construct. First solder a small brass ball to one end of a short length of stout brass rod, and then bend the latter to the form indicated in Fig. 30, at A, and afterwards solder it at about two inches below the knob of an ordinary Leyden jar, in the manner shown in the above cut. When

this has been done, carve a small wooden figure about the height of the jar to represent a sportsman with a gun at his shoulder, and then paint the figure in suitable colours, after which a small wooden stand, shaped in the form indicated in the cut, should be carefully moulded on which to stand the jar and the figure, the latter being attached to the base by means of a couple of screws and some glue. Before finally fixing the figure to the base, it will be necessary to polish or varnish the latter, and then cover the entire upper surface with a sheet of tinfoil cut to the required shape and then pasted on the wood — any wrinkles or creases being smoothed down flat by means of a piece of wadding or cotton-wool. Two or three pieces of pith are now cut to resemble birds, and then attached to the extended arm of the jar by means of silk threads, after which the apparatus is finally arranged in the manner shown in Fig. 30. The gun should be placed in metallic contact with the outer coating of the jar by means of a strip of foil led from the gun down the side of the figure to the foil-covered base, and the gun—which may be made of metal—should be furnished with a small knob at the end. On the jar being charged, it will cause the birds to rise and fly as far away from the central knob of the jar as the length of the silk threads will allow, and, as soon as the jar has become fully charged, a spark will pass from the knob of the jar to the gun, thus discharging the jar and causing the birds to fall as though shot. Small carved Swiss figures, suitable for this purpose, can now be obtained from any toy-shop at very reasonable charges, and one of these can generally be found which will answer the purpose with but slight alteration.

*Lane's Discharging Electrometer* (shown in Fig. 31) is a very useful appliance for regulating the sparks given off by a jar, and is almost identical in principle with the Sportsman jar, above described. First obtain a pair of small brass bedstead knobs, and then drill a hole on opposite sides through the centre of each one. When this has been done, one of the knobs should be tightly fitted on to the stem of an ordinary Leyden jar, to which it is affixed, about midway between the knob of the jar and the wooden cover of the latter, by means of a touch of soft solder. A 6 in. length of stout brass rod is now bent in the form of a ring at one end, and then made to fit tightly into the holes drilled through the other knob, after which a small brass ball is soft soldered on to the straight end of the rod. The rod will not require to be soldered, but should be arranged in such a manner as to move stiffly through the knob. Thus prepared, an 8 in. length of soft glass tubing of suitable diameter to fit the open ends of the two knobs is now softened in a Bunsen flame and then bent up to right angles at about a couple of inches from one end, after which the short arm of the glass tube is cemented into the knob provided with the adjusting rod, the remaining end of the glass stem being attached in a similar manner to the knob of the Leyden jar.

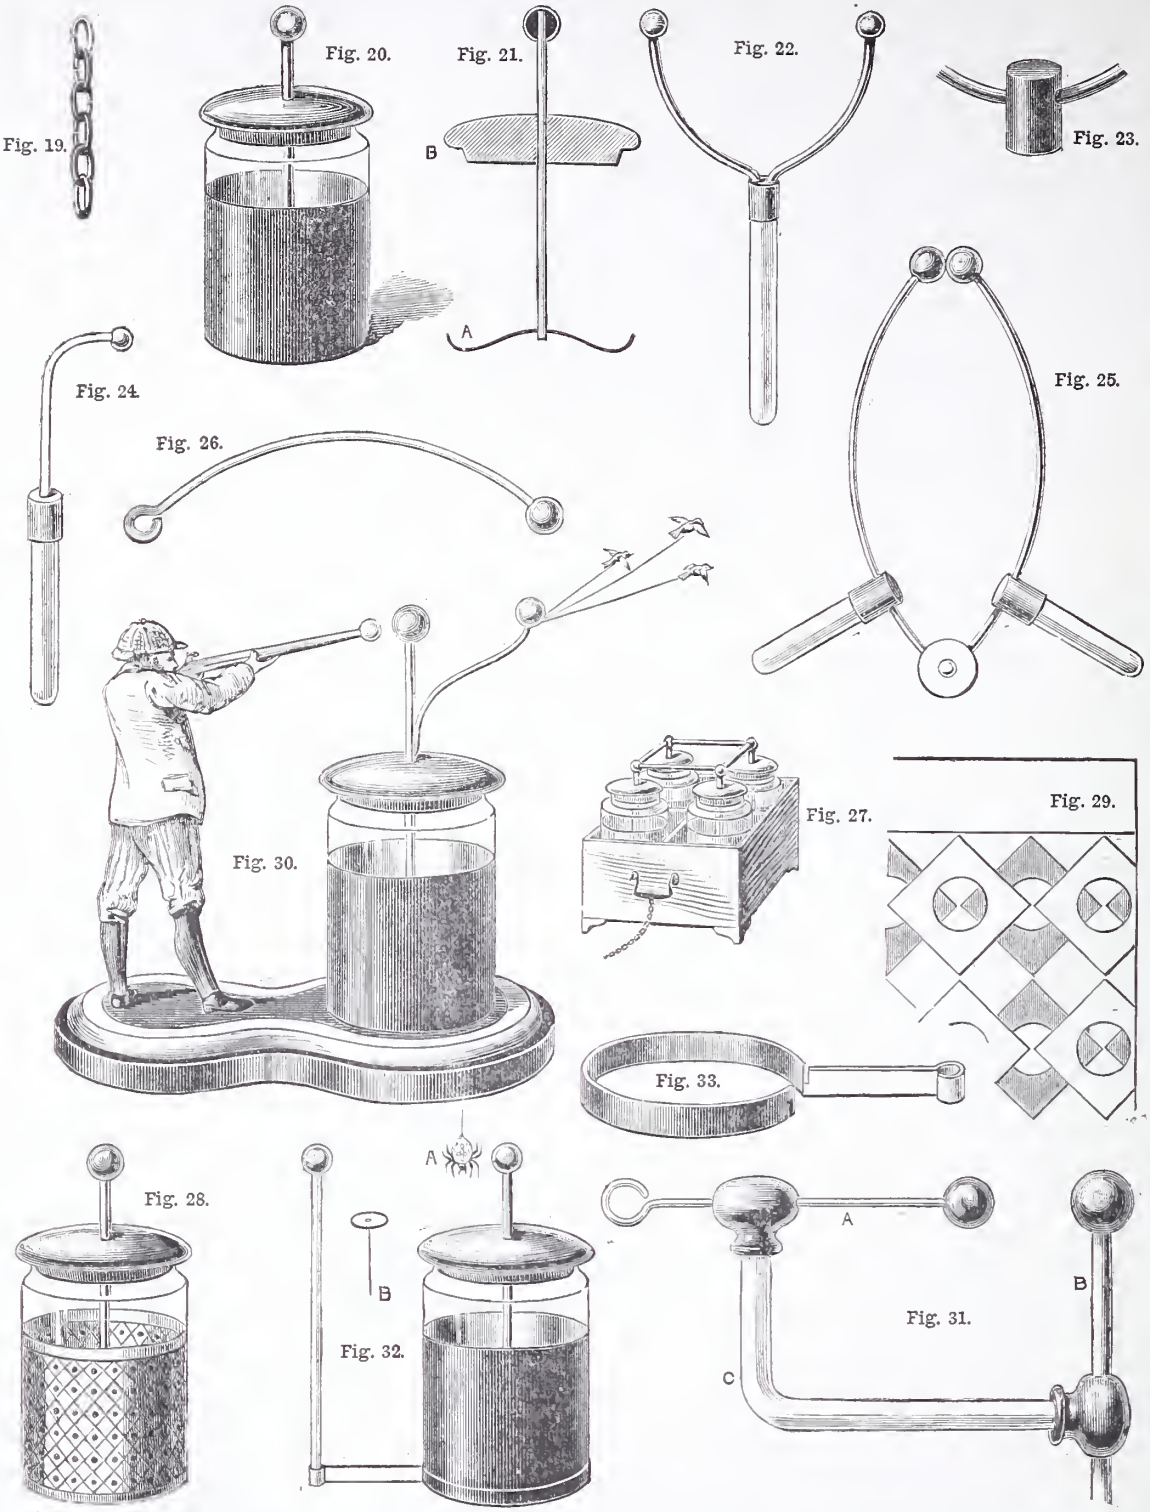

Fig. 19.—Brass Connecting Chain. Fig. 20.—Leyden Jar. Fig. 21.—Section of Cap and Conducting Fittings of Jar—A, Spring; B, Wooden Cap. Fig. 22.—Discharger. Fig. 23.—Alternative Plan for Cap of Discharger Handle. Fig. 24.—Director. Fig. 25.—Jointed Discharger. Fig. 26.—Arm of Jointed Discharger. Fig. 27.—Leyden Battery. Fig. 28.—Diamond-spotted Jar. Fig. 29.—Enlarged Detail of Diamond Coating. Fig. 30.—Sportsman Jar. Fig. 31.—Lane's Discharging Electrometer—A. Adjustable Stem; B, Stem of Jar; C, Glass supporting Stem. Fig. 32.—Spider Jar—A, Spider; B, Card Disc from which Spider is suspended. Fig. 33.—Brass Collar for Spider Jar.

When in use, it is simply necessary to hang a chain from the loop of the adjustable arm, and then twist it round the base of the jar. It will now be readily understood that, by pushing the adjustable arm in or out of the insulated bearings, it will increase or diminish the distance between the two knobs, thus regulating the strength of spark obtained.

*The Spider Jar* (which is illustrated in Fig. 32) is an amusing method of slowly discharging a Leyden jar, which finds great favour with young folks. A suitable length of ⅜ in. strap brass should be bent once round an ordinary Leyden jar, with 4 in. of the metal bent out at right angles from the jar. A slot is now filed from the upper edge to half the width of the metal just at the angle where the straight portion joins the ring, after which another slot is filed to a like depth at the extreme end of the ring, but from the under side, as will be seen by reference to Fig. 33, which represents the collar ready for attachment to the jar. By this means the ring may be bent round the jar and thus locked together securely. The extreme end of the straight arm is now bent in the form of a small loop, into which a stout brass stem is fixed in a vertical position by means of soft solder, a small brass ball being soft soldered to the upper end. A small piece of pith is now carefully cut and painted to resemble a spider (see A, Fig. 32), being provided with a few pieces of dried grass to represent the legs. When ready, it is suspended from the ceiling by means of a silk thread passed through its body and then knotted, the other end of the silk being passed through a hole in a small disc of card, to which it is secured by another knot (see B, Fig. 32). Thus prepared, the disc of card is gummed to the ceiling, with the spider suspended at a convenient height over the operation table. If the jar is now charged in the usual manner and then placed in position on the table, with the spider suspended between the two knobs, it will be alternately attracted backwards and forwards from one knob to the other, until the jar is finally exhausted.

The above are a few of the articles which may be utilised as accessory apparatus to the Winter Electrical Machine. In the three papers to follow this I shall describe others, and thus put the reader in possession of the means and mode of making things which may be fairly described as electrical toys.

## A CYCLE HOUSE.

BY J. H.

JOINTING AND FITTING—POSTS—HORIZONTALS—RELATION OF UPRIGHTS AND HORIZONTALS—FIXING POSTS IN GROUND—TOP FRAME—FITTING OF SASH—BOARDING—DOOR—FLOORING—FELT—TAR.

*Jointing and Fitting.*—I will now describe in detail the jointing and fitting of the various members of the house the general construction of which was shown in the previous article.

*Posts.*—Taking first the four uprights, A, A, B, B (Fig. 4, page 513), allow 2 ft. to go into the ground, pointing the ends with an axe. These ends will be either tarred or burned. The latter is the better method, and the operation simply consists in holding them in a wood fire for two or three minutes until the surfaces are charred and well blackened. They will then resist damp without rotting for a much longer period than if they were put into the ground without any preparation whatever.

*Horizontals.*—Into these uprights will be mortised the bottom horizontals, C, C, and D, D. Note that these are not on the same plane, but C, C, are higher than D, D, by the amount of their thickness, or their depth—3 in. There are two reasons for this; one is that better mortise and tenon joints can be made by this arrangement, because the tenons of C, C, and D, D, can go right through the uprights instead of meeting in the centre, as would necessarily be the case if the bars were in the same horizontal plane. The other is that the bars, C, C, form with L, L, good supports for the flooring boards.

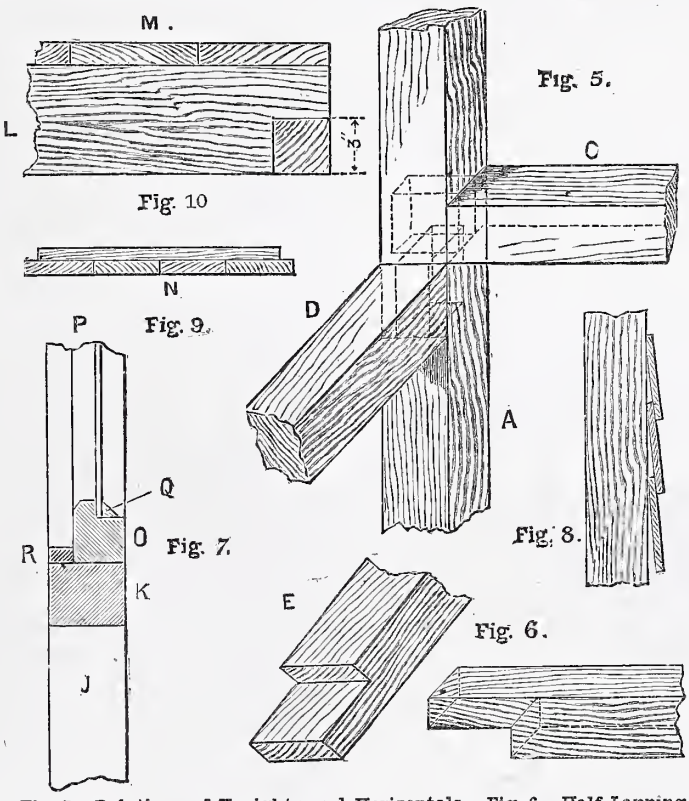

Fig. 5.—Relations of Uprights and Horizontals. Fig. 6.—Half Lapping. Fig. 7.—Fitting of Sash. Fig. 8.—Fitting of Boarding. Fig. 9.—Battened Door in Section. Fig. 10.—Flooring.

*Relation of Uprights and Horizontals.*—Fig. 5 shows the relation of the uprights and their two horizontals. The making of tenoned joints has been frequently described in WORK, and I need not, therefore, occupy space therewith. For rough outdoor work no glue is used, but a tight-driving fit made between tenon and mortise. Some paint or tar may be smeared over, and the joints should be either wedged or pinned.

Before the tenons are finally secured into the mortises, it will be advisable to cut the mortises in the front horizontal, C, and in the end horizontal, D, D, to receive the tenons of the uprights, J, J, for the window-sash, G, G, for the door, and H, H, for the support of the boarding. Then, the main framing being thus prepared, the posts, A, A, B, B, can be driven into the ground.

*Fixing Posts in Ground.*—There is not, however, much driving required. The proper way to fix the corner posts is this:—Dig four holes, about 18 in. deep, in the positions to be occupied by the posts, and drop these—the bottom horizontals being already finally tenoned and fixed—into those holes. Drive them with a sledge down to a firm bedding—six or eight inches will be sufficient, dependent on the nature of the soil. At the same time, see that the horizontals lie quite in winding with one another. When this is done, shovel a quantity of small stones into each hole, and ram them tightly round the posts with a mason's rammer, or with a sledge, or other suitable implement. Earth may be afterwards thrown amongst the stones and rammed down.

*Top Frame.*—Prepare the top frame, either by tenoning the corners of E, E, and the outer bars, F, F, or by making a half-lapped joint (Fig. 6). Half-lapped joints will be held with screws or with wooden pegs. Tenon the cross-bars, F, F, into E, E. The frame will then be laid bodily on the uprights, and spiked firmly upon these with 5 in. nails. The verticals, G, G, J, J, H, H, may be tenoned into the top rails, E, F, F, or abut simply, and be fastened with 5 in. nails. This completes a good firm framing, to which the rest of the work has to be attached.

*Fitting of Sash.*—An old sash, bought of any builder, will be fitted between J, J, K, and E. The sash, of course, must be bought at first, and the frame made to suit. There is no difficulty in fixing. The size of the recess is the same as the outside dimensions of the sash. The latter is made to rest against strips nailed inside the recess. Fig. 7 shows this in section, where K is the horizontal rail, J a vertical rail, O the sash-frame, P the glass, Q the putty, and R the strip that keeps the sash in place. A few screws or nails, driven in diagonally, may unite the sash to the rails.

*Boarding.*—The ⅜ in. boards on sides and roof are fastened with 1 in. wire nails to the frames; the overlaps are about 1 in. (Fig. 8).

*Door.*—The door, N, is made by battening 1 in. flooring board together, as shown in section, Fig. 9. It is hinged with strap hinges, not butts, and fitted with a staple for the padlock, a staple also being fastened into the post to correspond.

*Flooring.*—Two joists, L, L, to carry the floor, are fitted as shown (Fig. 10). The height of the shouldered portion is 3 in., equal to the depth of the quarterings of the frames. The boards, M, are then nailed on joists, L, L, and on frame timbers.

Felt is nailed on the roof with flat-headed nails, sold for the purpose. The house is tarred with two coats of tar. Shelving is put inside to carry oil-cans, spanners, and so forth.

## HOT-AIR ENGINES.

BY FRANCIS CAMPIN, C.E.

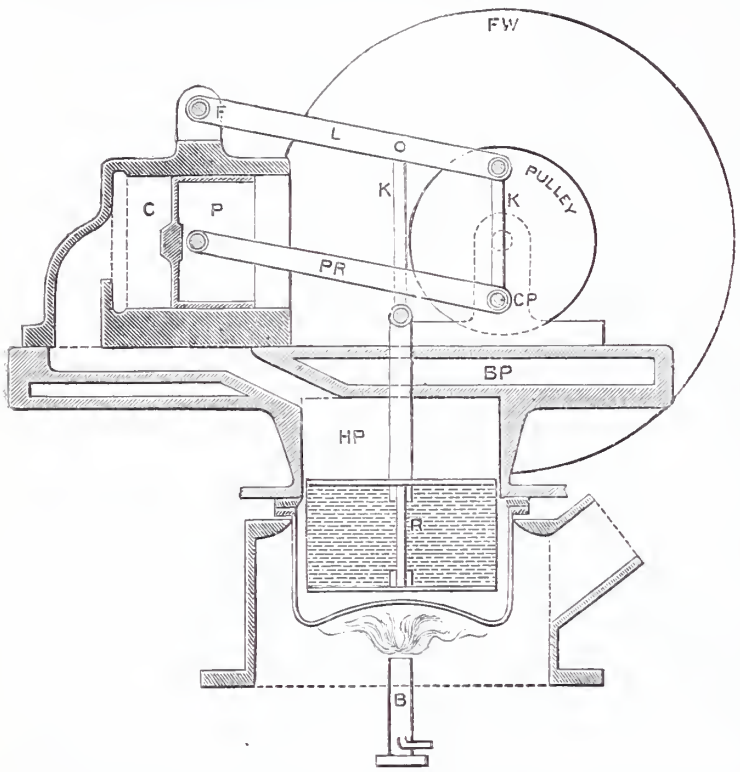
IN the early days of steam engineering Mr. James Stirling pointed out the economy that might be expected from the use of

heated air in place of steam in an engine. Subsequently Messrs. Ericson and Braithwaite took the matter up, and a steam vessel was refitted with caloric engines, as they were then called. This attempt was a failure—the late Mr. John Braithwaite told the writer that while the engine saved $10,000 in fuel, $100,000 worth of machinery was burnt out. This was in 1859.

Since that time many improvements have been made in hot-air engines, chiefly directed towards preventing the burning-out of the working cylinders, but on a large scale none of these have been successful.

Methods of applying water to the working parts have been used, but with the inevitable result of wasting fuel, for heat so abstracted must be a direct loss.

For small powers, however, there is a market for hot-air engines, and the best that I have seen is that made by Messrs. Potter & Co., in accordance with Robinson's patent. These engines may be driven by gas burners up to one-eighth horse-power, the gas being consumed in a Bunsen burner, so that there is no smoke whatever, or any escape of uncondensed gas.



A perspective view of the engine was shown in page 570, and the figure here given is a vertical section of the same. In this, C is a single-acting cylinder in which a trunk piston, P, works. The trunk piston is connected by a rod, PR, with a crank-pin, CP, fixed in a disc on a shaft which carries a fly-wheel, FW. Connected to the same crank-pin are links, K, K, which operate a rocking lever, L, and through links, K, K, actuate a plunger, R. The plunger, R, works in a hot-pot, HP, beneath which is a Bunsen burner, B. The rear end of the cylinder, C, communicates with the hot-pot, and the atmospheric air contained between these vessels is alternately expanded and contracted by the action of the regenerating plunger, R, and the burner, B. When the plunger, R, descends heated air passes up through the metallic gauze layers with which it is filled, and acts on the piston, P, which then makes a working stroke; the regenerator then rising absorbs the remaining heat from the air passing through it, and the momentum of the fly-wheel makes the return stroke.

These engines may be purchased at the subjoined prices :—

| Nos. | Diameter of Cylinder. | Approximate Power. | Fuel recommended. | Prices. |
|---|---|---|---|---|
| | inches. | | | £ s. d. |
| 1 | $1\frac{1}{4}$ | | Gas. | 4 4 0 |
| 2 | $2\frac{1}{2}$ | | ,, | 6 10 0 |
| 3 | 4 | $\frac{1}{32}$ h.p. | ,, | 10 10 0 |
| 4 | $5\frac{1}{2}$ | $\frac{1}{16}$ h.p. | ,, | 16 10 0 |
| 5 | $7\frac{1}{2}$ | $\frac{1}{8}$ h.p. | ,, | 25 0 0 |
| 6 | 10 | $\frac{1}{4}$ h.p. | Coal or Coke. | 33 0 0 |

This is a very interesting little engine, and is worth a little thought, especially in regard to the regenerator, R. I do not want any of our readers to be led into the idea that this regenerator gives us "perpetual motion;" it merely absorbs residual heat from the air passing from the cylinder to the hot-pot, and it gives that heat back to the air re-entering the working cylinder; but a certain amount of heat is converted into "work" by the action of the engine, and this heat is supplied by the Bunsen burner, B. The bed-plate, BP, of the engine is made hollow, so that water may be circulated through it if desired.

As it has been said above, a perspective view of the exterior of an engine on this principle was given on page 570. It was thought, however, that many readers of Work would be desirous to obtain a description of the internal construction and arrangements, which was not given in the notice itself, and hence the appearance of the article and diagram by which the missing link is supplied.

## OUR GUIDE TO GOOD THINGS.

*** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of Work for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of Work without charge, the notices given partake in no way of the nature of advertisements.*

89.—Forty Plates on Building Construction. Some time ago I had the pleasure of noticing in Work some volumes of a technical character prepared and written under the auspices of the Polytechnic Institute, Regent Street, London, W., and published by Messrs. Cassell & Company, Limited, La Belle Sauvage, Ludgate Hill, London, E.C. I have now to draw the attention of the readers of Work to a handsome folio volume entitled "Forty Plates on Building Construction," by Mr. Charles F. Mitchell, Member of the Society of Architects, Member of the Architectural Association, Lecturer on Building Construction at the Polytechnic Institute, and Registered Teacher of the Science and Art Department, and City and Guilds of London Institute. Mr. Mitchell has been assisted in his task, or rather in his labour of love, by the lecturers of the Polytechnic Institute. It will be useful to reproduce here at length Mr. Mitchell's prefatory remarks, which show far more clearly than anything I might write to this effect, the *raison d'être* of the work itself. "These plates," he says, "have been prepared to render assistance to students studying for the examinations in the elementary, advanced, and honours stages of 'Building Construction and Drawing' conducted by the Science and Art Department, and for the examinations in carpentry and joinery, brickwork and masonry, and plumbing of the City and Guilds of London Institute. I trust they will be found of service to those professionally or practically connected with the building trades. I also take this opportunity of thanking my colleagues for their help in the revision of those plates against which their names are placed, and to Messrs. E. G. Davey, Polytechnic Medallist, G. A. Mitchell, National Honours Silver Medallist, and F. G. Conyard, National Competition Prizeman, for the assistance rendered in executing the drawings. The text for the plates, together with additional subject matter and illustrations, will most probably be published early in 1892, under the title, 'Part II.—Building Construction and Drawing.'" Regarded as a whole, the volume may be described as a bird's-eye view of the various operations combined in the building of a house from the foundation to the completion of the roof, with all details of internal work in joinery, staircasing, etc., and all that is needful to be carried out with reference to plumbing, ventilation, and hot and cold water supply. To mention *singulatim et seriatim* the subject matter of each plate would take far more space than I have at my command, and it will be sufficient, while touching on this, to say that Plates 1 to 8, inclusive, are devoted to brickwork and masonry (1); Plates 9 to 22, and 25 to 29, to carpentry and joinery (2); Plates 23, 24, 30, 31, 32, to plumbing (3); Plates 33 to 37 to constructional ironwork (4); and Plates 38, 39, and 40 to details of a small town residence, with complete sets of working drawings illustrating fire-resisting construction, sanitation, ventilation, and the necessary arrangements for laying on hot and cold water in various parts of the dwelling. The price of the volume complete, strongly bound in cloth, is 10s. 6d., but those who do not require it in this form are privileged to obtain the plates in different sections, as described and numbered above: No. 1 at 1s. 6d., No. 2 at 3s., and Nos. 3, 4, 5 at 1s. each; or copies of any single plate may be obtained in quantities of not less than one dozen at 1s. 6d. per dozen. This offers a great advantage to technical schools, in which this work will be found of the utmost service, and to classes in which any particular branch of the building trades is under consideration; and, owing to the number of students in the class, a single plate among so many would be well-nigh useless. The drawings themselves are well defined and clearly executed, and in all cases are drawn to, and accompanied by, a scale of feet showing the proportions of each piece of work, or species of work, that is illustrated, and affording facilities for enlargement, also to scale, a kind of practice in drawing office work that is extremely useful to and much needed by students. As a work of reference it should be found in the office of every builder whether on an extensive or limited scale, where it will also prove of service in reminding its owner and user of the right thing to do and the right way to do it, at times when through stress and pressure of work and the worry that is consequent upon it, the brain will not answer the helm quite so readily as it will when all is plain sailing and there is nothing to distract and weary and divide the attention.

The Editor.

# SHOP:

## A Corner for Those who Want to Talk It.

*** *In consequence of the great pressure upon the "Shop" columns of* Work, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—Letters from Correspondents.

**Patent.**—S. E. (*Upper Clapton*) writes:—"'It is amusing to see the readiness with which persons entirely ignorant of a subject will set themselves up to guide and instruct others, and what useful and infallible authorities they consider themselves.' In these words our friend C. E. commences one of his usual instructive and useful articles, on p. 492, No. 135, and his words are perfectly true as applied to the nonsensical and misleading statements made some time ago by C. C. C., and in other papers by many other would-be authorities in such matters. But C. E. has himself made a serious slip in the article in question, and I hasten to correct it, as if any of your readers rely upon this particular statement of his, they may regret it when too late. C. E. tells us (speaking of the filing of the complete specification) that, 'if it is found that what has to be done cannot be completed within that term (nine months), an extension of time of one, two, or three months may be applied for, for one of the three periods named, with the stamps for fees of £2, £4, or £6 impressed upon the application; but *no further* extension of time will be granted.' The fact of the matter is that one month, and one month only, beyond the original nine months, can be obtained for filing the complete specification, and the stamp duty required on the application form is £2. I am sure that C. E., in his usual fairness, will be ready to admit his error in the case. As an inventor myself, I have found that what you want is an old-established, experienced agent, doing business in a comparatively small way, and whose personal attention you may rely upon obtaining."

**Patents.**—S. G. T. (*Penarth*) writes:—"Many of your correspondents tell us novices how to go about getting a Patent, and in a very clear and able manner; and there is no doubt but that anyone of average ability could get his ideas patented by following their directions. Among other things, they tell us to go and search the Patent records before we apply for a Patent, and see if we have been anticipated. Now, I have what I believe is an excellent idea for a cushioned tire for bicycles, etc., and I went, before applying for protection, and searched the Patent lists to see if any other 'inventor' was before me. I looked through all the lists of sealed Patents for this year, but found nothing like mine, but on searching the lists of applications for Patents, I found that there were about two a day for the last three months for the same kind of thing. Now, can any of your correspondents tell how we are to know that some of these applicants may not have the very same thing as ourselves, and being before us, of course, have the preference? A little more information would be very useful upon this point, and doubtless some kind reader will supply it without appealing to your specialist for so small a matter."

**Boot for Shortened Leg.**—J. F. (*Glasgow*) writes:—"Could you kindly send me Mr. Tyrrell's address (see Work, No. 135, p. 490—Improved Boot for Shortened Leg), as I wish to make inquiries about above?"—[No addresses can be given in Work elsewhere than in the advertisement columns.]

**The Utility of Work.**—The Rev. L. M. (*Roscrea*) writes:—"I have often thought of writing to you to say how pleased I am with Work. It is a splendid paper for all professionals as well as amateurs, and I have tried to show my appreciation of its value by recommending my friends to subscribe to it. I am glad to say half a dozen, at least, have been wise enough to follow my advice, and they all agree in saying it is 'A 1.' I say this by way of encouragement, Mr. Editor—if you need any—though I think the success of Work ought to encourage the most despondent of editors, and I know *you* do not belong to that class. Now see what an advantage Work has been to me. Four years ago my 'kit' consisted of an axe, a rusty saw, and a sardine knife. But Work put different ideas into my head, and showed me the way to carry them out. First I made the Cheval Screen Escritoire. Then I took up the Battlesden Car—in spite of gloomy prophecies by my friends as to the result when the trial trip was made. Then came other things, among which I may mention folding table, two overmantels—one from design by Mr. Gleeson-White, the other by Mr. Adamson—a settee, wardrobe, dressing-table, and a dozen other things; the last a zither, which my wife is now playing. So you see Work has been a real source of profit to me to say nothing of the pleasure, and with regard to the last item, I have spent some of the happiest hours in my 'shop' I ever spent. I am not afraid now to tackle any job that lies in the carpentry line, for the reading of Work has been as good as an apprenticeship to me. I live within a dozen miles of one of your contributors, the Rev. J. L. D., who has been very good to me in giving me hints; and Opifex was once in this diocese. I must apologise for trespassing on your valuable time, but after all the pleasure and profit I have derived from Work, the least I can do is to write and express my gratitude."—[Insertion is given to this letter because it not only illustrates the extent to which the publication proves serviceable in the hands of the intelligent worker, but because it contains an excellent suggestion bearing upon the large circulation of Work. If the many subscribers who write anxiously desiring to "do something" for Work were to follow the Rev. L. M.'s example, there is no saying where the circulation of the Magazine would end.]

**Framing Engravings, etc.**—T. S. (*No Address*) writes:—"I so often see good engravings spoiled by careless framing that I am induced to send to your readers the way in which the work should be done instead of the usually imperfect mode. A valuable engraving is sent to be framed, and if nine out of ten are examined they will be found to be done as follows: The glass is put into the frame and strips of paper pasted round more or less carefully, thus the frame and glass are secured together; then the picture stretched on a frame, or stuck to a mount, is put in with a few brads, and brown paper stretched over all. The effect of this plan is that, however perfectly it is done, the act of cleaning the glass presses the brads down and loosens the paper that is intended to secure all dust-tight, and in the course of a year or two a brown streak of smoke-dust extends like a shadow across the picture, often impossible to remove again, or a general cloud veils the picture, causing a proof engraving to look like one of the last dozen prints taken off the plate. Now the proper way is to carefully clean the glass—and even in this some extra care is necessary, as brisk rubbing to a sheet of glass will make it electrical, and every particle of dust will fly to it, and require some trouble to remove—and you will find when the work is done, that your glass has a quantity of fibres of the cloth you used, or any other small particles that happened to be near, between it and the picture. Place the glass cleanest side up on the table, projecting an inch or two over the edge; lay the picture on it, and if it has no mount, a sheet of brown millboard, or at least a sheet of stout paper should be added. Then with a straight-edge cut some strips of brown paper of width sufficient to bind the glass and picture together (about ⅜ in. on the glass and ½ in. on the back); add to this the thickness of glass and picture. Damp the strips and glue them on to the edge, like what the ladies and tailors call binding; follow round all four sides, so that, when the work is done, all that is required is the ornamental frame, and something to hang it by. The picture, but for appearance, is perfectly dust-proof, and will always look bright and clean. It will sometimes happen that the frame has a very narrow rebate, and the binding will show, so when quite dry you had better pop it into the frame to see how it looks, and if any binding shows, run a pencil-mark round; take it out, and with straight-edge and point of knife, cut down through the binding to the glass, when the superfluous binding can be easily scaled off, leaving the glass quite clean. I have often had to leave only ⅛ in., but if properly done it is enough. Another piece of millboard, or a thin wood back, secured with a few brads and a damped sheet of brown paper glued over all, will make a complete job. Thus the frame is, as I have before stated, merely as a means of support and ornament to the picture, which, for protection against dust, etc., is completely framed without any frame at all. In fact, I have often stuck a strip of gilt paper on the glass over the binding, and glued a loop on the back and hung up small photos without any frame at all."

### II.—Questions Answered by Editor and Staff.

**Die Cutting and Stamping.**—M. (*York*).—(1) I have made inquiries as to the presses you require; and, no doubt, you have received price-lists, etc., by post, as great pressure on the columns of "Shop" will prevent this appearing for some time. The "Model" Press Company, of Farringdon Street, E.C., have them in all sizes; and Mr. John Esson, of Fetter Lane, Engineer and Printers' Broker, has several, second-hand. The specimens of relief stamping are very good; the engraving of the dies, however, seems to me to be rather shallow, if anything. (2) The black composition for filling in door, window, or coffin plates, whether zinc or brass, is best black sealing-wax; and for red letters, best red sealing-wax. The plate should be heated till the wax completely fills up the cutting; then grind off all burr left by the tool, and all superfluous wax, with a stone and water first: afterwards polish with oil and crocus (finest emery powder), and, lastly, with whiting and oil.—J. W. H.

**Type Cases—Soda Crystals.**—No Name.—Mr. John Esson, Printers' Broker, Fetter Lane, E.C., will, I think, give you the information you want as to the half-cases you require, and, probably, has some second-hand ones in stock. Any large oilman, such as Mence Smith, would supply you with the soda.—J. W. H.

**Paraffin Mixing.**—W. S. (*Glasgow*).—It is a difficult matter to connect your bare inquiry with any purpose or calling; otherwise, to answer it usefully might be a more definite matter. A friend, who is an analytical chemist, tells me he would mix them by turning a current of steam into the paraffin, or that alcohol would help to effect the purpose. My own experience in trade matters may be more serviceable, perhaps, in your case. Water—preferably "soft" water—can be amalgamated with oil paint by a continuous "agitating" action; and hot oil and turpentine may be readily mixed with water-paint liquids in a similar manner. In both instances the purpose is effected sufficiently thoroughly for spreading the mixture upon flat surfaces. From this I assume that paraffin—*i.e.*, petroleum—could as readily be amalgamated with water, especially in the small proportion of the former you name. I expect equal parts, agitated in a bottle, would soon mix, and then could be turned into the bulk of water. If there is any special chemical article used in certain processes for assisting the mixing action, I should suggest *borax* as being the factor. Why not state, simply and openly, your object and purpose?—F. P.

**Veneering.**—Ivanhoe.—You cannot do better than read the articles on Veneering in Vol. I. of Work. They deal thoroughly with the subject, and, having so recently appeared, it is impossible to go over the ground again in "Shop." Of course, after reading them, if you find yourself in a difficulty, write us, and you may be assured every assistance will be given you; but, after the very lucid directions which were given about the side of the wood on which the veneer should be laid, I hesitate to say the heart side, in case you should still misunderstand which side. If you have not got all the back numbers of Work, and do not care to buy them—though I strongly advise you to invest a penny in an Index to Vol. I., so that you can see what subjects have been treated—you will find a "few hints" (much good may they do you, for I rather think you want full directions) on a sliding-frame dining-room table in the number of Work for 7th June.—D. D.

**Distemper.**—Beeswax.—The amount of *genuine* yellow beeswax which—having been already scraped into shreds and then dissolved in oil of turpentine—should be added to a half-bucketful of distemper, in order to make a *tempera* paint for good decorative work, would be about 4 oz; or for a good pailful, prepared according to the instructions quoted on p. 787, Vol. I., the proportions would be ½ lb. pure beeswax in 1½ pints of turps, the two well amalgamated, and then added as directed. Respecting your second query, sufficient finest isinglass to make a pint of glass-gilding mordant could be readily placed upon a shilling. For further information, see answer "Acid and Gilding," when published.—F. P.

**Bell Telephone.**—J. R. M. (*Walton*).—I do not know of any very cheap telephone which would answer your purpose, unless you like to use the apparatus called "The Lovers' Telegraph." It can be made with two empty meat tins. Remove the bottom of each, and, in lieu thereof, stretch a piece of parchment over the end; in the centre of these bore a little hole, and pass a cord or wire through them, connecting both tins together, with a knot or button on the inside of each. The string must be kept strained when the instrument is in use. Words spoken into one cylinder can be clearly heard by a listener at the open end of the other. This is really a mechanical telephone, and, if properly made and connected, would answer your purpose very well. But I think you should try and make a set of telephones, with transmitter and receiver at each end, such as have been illustrated fully in Work already. They are as cheap as any I know. Sometimes you know that a cheap thing turns out very dear in the end. As all the necessary connections, etc., have been given before, it is not worth while taking up space with rough drawings. And, as you are a constant reader, you will have no difficulty in getting what you want from back numbers.—W. D.

**Micro-polariscope.**—B. J. T. (*Southsea*) asks if the angle of 26°, as given in my article, is the correct one, and if it has been given from experience, as in Ganot's "Physics," 54° 35' is stated to be the proper angle for glass to polarise. I will answer the last question first, and say that I arrived at my conclusions after long and exhaustive experiments, and the angle I have given is the one by which I have worked. From experiments I have made, I am led to think that the same angle does not answer for all kinds of glass, and, to obtain the best results, experiments must be made. Different writers seem to range from 50° to 60°. That being so, the discrepancy between such an angle and that given by me is only in appearance. Before I began experimenting, I read, "Glass will polarise at an angle of, say, 54°," by which I understood an obtuse angle containing 54°. I accordingly made a tube, and cut off the end at this angle; the result was, not the least polarisation. I was much perplexed thereat, and wondered where the mistake could be. I began experimenting, gradually tilting the glass at a more acute angle, until I obtained polarisation. I now found, by measurement, the angle at which I was working was just exactly the complement of 54° or 26°. I then understood that what was intended was that 54° were to be cut off. This is really the solution of the seeming difficulty. Having been

perplexed myself in the matter, I thought it would simplify matters to say that the tube should be cut at an acute angle containing 26°.—O. B.

**Planing.**—J. R. (*Hillsborough*).—You give no clue as to your acquaintance with wood working; but, probably, it is of a very recent date. I could advise better if you had given fuller particulars. I join with our Editor and contributors in asking our querists to ask their questions very fully, giving particulars of the special difficulty that presents itself, in order that we, who are still learning, may learn to give full, exact, terse, and helpful replies. For planing pieces of wood ½ in. square, 2 ft. long, use a jack-plane, well sharpened and set. Read how to do this in WORK, No. 20. With proper treatment, the wood does not want *fixing* on the bench; but if J. R. has many pieces to plane to a size, it may be worth while to make some contrivance to assist in doing this. I have a paper in hand on this very subject, which I will send to the Editor as soon as I am able, and hope it will be of use to J. R. and many others.—B. A. B.

**Cog-Wheels.**—A. Y. (*Blackburn*).—When the saw bench on p. 177, Vol. II., was drawn, I thought chiefly of the most convenient height of handle, doing away with slip, and getting the advantage of a rapid revolution of fly-wheel. If these are obtained, by all means have the other details to suit yourself. I should apply for cog-wheels to Lloyd, Steelhouse Lane, Birmingham, or Barker's Gas Engine Manufactory, Birmingham. If not successful in obtaining the wheels, I should try to get a second-hand mangle and wringer, or the wheels thereof, by Bradford, or Harper Twelvetrees; but without sizes it is impossible to advise. It would be best to get two cog-wheels and two pinions before deciding position of axles, as the exact size does not matter much. You want the saw to turn at least twelve times as often as you turn the crank. —B. A. B.

**Propeller Screws.**—F. M. (*Thornton*).—The area of screw blades should be determined by experience; but for those who have no opportuuity of so determining it the following rules will be useful. I give them for four-, three-, and two-bladed propellers. I H P = indicated horse-power of engines; $c$ = a co-efficient:—

$$\text{Total area of screw blades} = c\sqrt{\frac{\text{I H P}}{\text{revoluts. per min.}}}$$

In which formula—

$c = 15$ for four-bladed propellers;
$c = 13$ for three-bladed propellers;
$c = 10$ for two-bladed propellers.

The pitch of screw for propellers varies very much, and in our columns we have not space to deal with so wide a subject. You will find it all explained in Seaton's "Manual of Marine Engineering." The thrust of screw is also explained in the work referred to.—F. C.

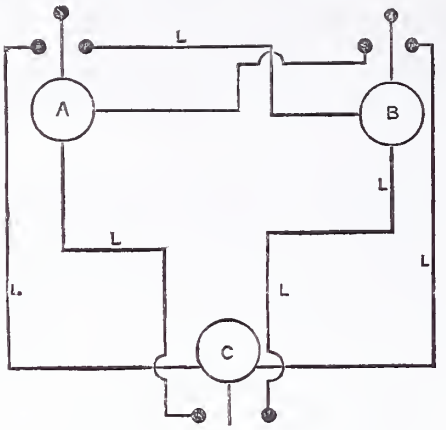
**Steel Hardening.**—A SUBSCRIBER.—No special method beyond the mere immersion of the articles to be hardened. The lead can be melted in any iron vessel; a ladle will do for small articles. The advantage of its use is that the temperature is nearly constant, and that the articles immersed can be left in the lead for an indefinite time without becoming burned. The steel is not oxidised as it is when put into the fire, but retains a clean surface. The lead should be free from corrosive adulterations, and be covered with charcoal while molten. Perhaps the following table, copied from a valuable and now rather rare book—Percy's "Metallurgy of Iron and Steel"—may be of service to you and others:—

TABLE OF THE COMPOSITION OF METALLIC BATHS FOR THE USE OF WORKING CUTLERS.

| *No.* | | *Composition of the Bath.* | | *Temp.* |
|---|---|---|---|---|
| | | *Lead.* | *Tin.* | *Fah.* |
| 1 | Lancets | 7 | 4 | 420° |
| 2 | Other surgical instrumeuts | 7½ | 4 | 430° |
| 3 | Razors, etc. | 8 | 4 | 442° |
| 4 | Penknives, and some implements of surgery | 8½ | 4 | 450° |
| 5 | Larger penknives, scalpels, etc. | 10 | 4 | 470° |
| 6 | Scissors, shears, garden hoes, cold chisels | 14 | 4 | 490° |
| 7 | Axes, firmer chisels, plane irons, pocket-knives | 19 | 4 | 509° |
| 8 | Table-knives, large shears | 30 | 4 | 530° |
| 9 | Swords, watch-springs | 48 | 4 | 550° |
| 10 | Large springs, daggers, augers, fine saws | 50 | 2 | 558° |
| 11 | Pit saws, hand saws, some springs | Boiled linseed oil. | | 600° |
| 12 | Articles which require to be somewhat softer | Melting lead. | | 612° |

Of course, a list of this kind must be taken *cum grano salis*, because of the great difference in qualities of steel. But the lead bath is valuable, nevertheless, and is used to a considerable extent. This ensures uniformity in tempering a number of similar articles; but where the clear fire only is used, the articles are enclosed in a cast-iron box, or a tube of cast or wrought iron, or laid upon a hot plate or bar. For small articles, a cylindrical tube of cast iron is as useful as anything.—J.

**Telephone.**—H. S. (*Stoke Newington*).—This is really a very simple matter when one thinks of it. Having fixed up your instruments in the various rooms, you will require three two-way switches. Carry a wire from station A through the switch to stations B and C. This done, go to station B, and carry the wire to stations A and C through another switch; and, having gone to station C, carry a wire through another switch to stations B and A, thus completing the arrangement. By following this out you will have complete control of the various instruments at the different stations. A simpler plan could not be adopted, although one which would,



Telephone Connections for Three Stations.

perhaps, save a few yards of wire might be devised; but it would lead to complications which would be difficult to get over. You will, of course, require a transmitter and receiver at each station, and also a bell for calling attention. I give above a sketch of the connections, although I think it is not necessary, for the instructions are plain enough, and would be easily carried out. In the sketch, A, B, C represent the three stations, and the heavy dots the switches. The arms of the switches are not shown. The L's represent the line wire. I hope you will be able to get over your troubles, and that your darkness will be illuminated by the above.—W. D.

**Spirit Graining.**—A. W. P. (*Leytonstone*).—Since your query was received, you have, doubtless, had a full answer in the paper devoted to the process which appeared in the Graining series, Vol. II. I should not advise you to try and make the paint mill, as they can be bought so cheaply of any painters' merchant. Crowden & Garrod, Falcon House, London, S.E., sell a very good one for 30s.

Paint Mill.

(I append illustration), which is computed to grind 6½ lbs. per hour. The next price is 40s., and so on up to 180s. To the trade, and for cash, there would probably be a reasonable discount off this. You cannot do better, I believe, than buy of Crowden and Garrod; but grinding one's own paint is poor economy at any time, unless one is situated far from manufacturing centres.—F. P.

**Zither Tuning.**—J. J. (*Belfast*).—You should write to the publishers, Cassell & Co., Limited, London, E.C., and enclose the necessary stamps for any copies of WORK you may require.

**Dynamo Design.**—H. D. H. (*Clevedon*).—If you are satisfied with the "mechanical details" of the design submitted to me, I very much fear you know little of the principles of dynamo designing. In the first place, the F.M.'s are badly designed. The channel is quite ⅛ in. too large, and the cores present an insufficient surface to the armature. The arch of the carcase should not be in one piece, but be slit, and the two pieces connected by a gun-metal bridge. Taking your own statement as being correct, the winding is altogether wrong. In a series wound dynamo, the armature resistance should nearly equal that of the F.M. In your machine the armature resistance is ·0078 ohm, and the F.M. resistance 3·130 ohms. Why have you put the wire on the armature in sixteen sections? Only one of these is effective for E.M.F. of current. You have only one yard of active wire on the armature, and this must be run at 5,000 revolutions per minute to develop an E.M.F. of 1 volt under the most favourable conditions. With a resistance of 3·130 ohms in the F.M. alone, you will get but a fractional amount of current in the outer circuit, even if the terminals are not short-circuited with a thick wire. Your best remedy now is to cut the arch of the carcase in two pieces, and connect the two parts with a non-magnetic bridge of gun metal or brass. Then see that one of the cores has a north polarity, and the other a south polarity. They should be wound in opposite directions to ensure this. You cannot alter the armature channel or tunnel, so must let that remain. Connect the armature in shunt with the F.M.'s and run it as shunt-wound dynamo at a speed of 5,000 revolutions per minute. Even then you will not get a powerful current from such a small and badly designed machine.—G. E. B.

**Electric Light Manager.**—T. (*Port Said*).—Your qualifications, as stated in your letter, should fit you for the duties of manager in an electric light installation. But you cannot expect an electric lighting company to take you on your own recommendation alone. I should therefore advise you to get your qualifications laid down on paper by your officers, and backed with the names of well-known men before you leave the service. Then you will have to make personal application to one or more of the electric lighting companies and ascertain whether they have a vacancy or not. Or advertise in WORK, the *Electrician*, or the *Telegraphic Journal*, for a situation. It is quite possible you may have to show your qualifications in the factory in a lower position, and thus work your way along by giving practical proof of your abilities. —G. E. B.

**Iron Girder.**—J. S. B. (*Poplar*).—The length of chord varies as the radius. We must first find the radius of the bottom chord, which is determined by dividing the square of span by eight times the camber, and adding half the camber: thus with span 75 feet, and camber 1½ inches (=$\frac{1}{8}$th foot)—

75 feet
75 „
375
525
$\frac{1}{8} \times 8 = 1$ ) 5,625 square of span.
5,625
$\frac{1}{16}$ = half of camber.
$5{,}625\frac{1}{16}$ feet = radius of bottom chord.
Add $8\frac{1}{2}$ feet = depth of girder.
$5{,}633\frac{9}{16}$ feet = radius of top chord.
Multiply by 75 feet = length of bottom chord.
28,165
39,431
$42\frac{3}{16} = (75 \times \frac{9}{16})$.
$422{,}517\frac{3}{16}$

This is to be divided by radius of bottom; the fractions may be dropped:—

$\frac{422{,}517}{5{,}625} = 75$ feet $1\frac{9}{16}$ inches, length of top chord.

You ought to allow 1 inch camber for every 40 feet of span. You will find the construction of girders practically treated in a series of articles on "Wrought Iron and Steel Girder Work," commencing page 171, Vol. I. of WORK.—F. C.

**Beer.**—W. G. G. (*London, S.E.*).—I am not aware of any book devoted specially to the after management of beers, but "The Theory and Practice of Modern Brewing," by Frank Faulkner, published at 21s., by F. W. Lyons, will be found to be an exhaustive treatise on the whole subject. The keeping qualities and condition of beers depend mainly on the quality of malt and hops used, and the skill with which the brewings are carried out. If any of these are defective, after management can do little to rectify and preserve. Thick and sour beer cannot be converted into good beer. The best judge of the quantity of finings is, in each case, the brewer who brewed the beer; different beers require different treatment. Warm weather undoubtedly affects beer, but beer can be, and is, brewed to stand such. Inferior qualities suffer most by the high temperatures.—APIS.

**Harmonium Articles.**—H. H. (*Barnsbury*).—No such papers have yet appeared, but some are in preparation.

**Discs for Electric Belts.**—J. W. (*Camberwell*).—I am not favourably inclined towards your proposed method of connecting the discs of copper and zinc. You are right respecting the dimensions of the discs. These may be of the size of pennies, or even larger, up to 1½ in. in diameter. You are also right about having a piece of flannel between the zinc and the copper discs, this flannel partition

acting as a porous diaphragm between the two elements. Now, the two elements should be connected as the plates of a battery are connected, not by a brass eyelet in the centre, passing through the porous diaphragm, but by an insulated conductor conveyed from the outside of the copper discs to the outside or edge of the zinc discs. These should be next the body of the wearer, and coated with thin flannel to prevent actual contact of the metal with the skin, or sores will result from irritation by the metal and its salts. The perspiration from the body will pass through the flannel, excite the zinc, and generate a current of electricity, which will pass through the moist porous diaphragm to the copper and be conveyed by the insulated conductor to the zinc of the next couple, and so on. When the two end discs are connected by the metal clasps of the belt, a current will circulate around the body. For further information I must refer you to "Shop," in Nos. 103, 115, 117, 120, 124, and 129.—G. E. B.

**Electric Gas Lights.**—GAS-L.—The instrument described by you, and illustrated by the sketches sent with your letter, is one of Clarke's patent electric gas lighters. The principles of its construction are similar to those of a Wimshurst frictional electric machine. Inside the outer fixed cylinder of ebonite there should be two quadrants of tinfoil, such as shown in your sketch, and six knobbed wires. Two of these wires should be connected to the tinfoil quadrants, two of them (opposite to each other) be carried up to form conductors for the outer circuit and connected to the insulated wires in the stem of the instrument, and the ends of the other two connected together. The connections may be made above the plate shown in your sketch, and these may be defective. They should be well insulated from each other, and may be improved by pouring melted paraffin on the plate. The inner or revolving cylinder has six strips of tin or copper foil on its inside surface. The spaces between these strips should be varnished with shellac (spirit) varnish, but do not varnish the strips of foil. When the cylinders are in position, the knobbed ends of the six wires must touch the strips of foil in the inner cylinder. The insulation of the outer cylinder may (as you suggest) be impaired. To remedy this, warm it before a fire, and paint it whilst warm with some of the shellac varnish, but do not coat the foils.—G. E. B.

**Bronze Paper.**—THORNHILL.—Write to Berry and Roberts, St. Bride Street, Ludgate Circus, London, E.C.—G. C.

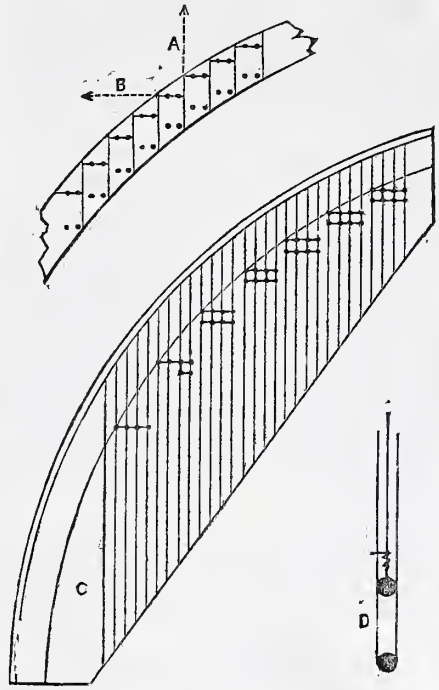
**Small Dynamo.**—H. H. (*Finsbury*).—As you are "only a starter at the game" of dynamo making, I should advise you to attempt something more simple and useful than trying to solve the problem of making "a small dynamo, weight about 1½ lb. complete, to fit in a box 3 in. high, 2½ in. wide, and 2 in. across," to give a light of 4 candle power when driven at about 2,200 revolutions per minute. I give your requirements here in order that some other reader may take up the problem and work it out for you if inclined to do so. As I do not think the "game" worth the candle, I relegate it to some one of those persons who find amusement in working out such problems. The "game" of dynamo making will require a little more study on your part than merely reading casually how to make a dynamo in the back numbers of WORK. I should advise you to read the instructions again, then "start" on one of the small dynamos mentioned on p. 644, Vol. II. of WORK. If you succeed with this, you will understand more about what you call a "game," but which is in reality a most serious study, than you do at present.—G. E. B.

**Safety Bicycle.**—J. J. (*Swansea*).—This subject has been treated in the following numbers of WORK:—107, 111, 115, 119, 124, 127, 132.

**New Invention.**—E. L. (*Netherton, Dudley*).—Our correspondent, as the matter is stated by him, is in no position to treat safely with the matter named; firstly, because there is no *proof* that he has any property to treat for; secondly, because he cannot *safely* treat for the sale of the plan until he has protected his rights, either by lodging a provisional specification or filing a complete. The first thing our correspondent should do is to ascertain clearly whether his invention *is* novel by a careful search and examination of all the published specifications relating to the subject, which may be seen at most of the public libraries—say, Birmingham, Manchester, etc. When he has satisfied himself that there has been no prior specification for his plan recorded at the Patent Office, he should then have prepared by competent parties, either a provisional or complete specification of his invention—properly illustrated with drawings in the latter case—and send them to the Patent Office, and when he receives the official notice of their acceptance, he may *then* proceed to negotiate for the sale or introduction of the matter. It would be the height of folly on his part to attempt to treat with anyone whilst his rights are unprotected, as it is too well known that what are called "trade" principles are not particularly noted for their abilities to distinguish the difference between *meum* and *tuum*, more particularly when the *meum* is most likely to be benefited by the operation.—C. E.

**Boot Studs.**—BARKIS.—E. Penton & Son, Mortimer Street, London, W., will supply you with Ellis's patent hoot studs. There are three sizes, large, medium, and small—price, sevenpence per doz.; per gross, 5s. 6d.; keys, with awls, for same, 3d. each. I should think any large grindery warehouse near you would keep or get them for you.—W. G.

**Piano Bent Side Plates.**—W. H. M. (*Burgess Hill*).—It is quite correct what you have read. You make a line on the bent side 2 in. from the sound-board edge. You start your first parallel line where your 2 in. line crosses the vertical lines. Perhaps the accompanying sketch makes it more plain for you. If you read the paper on "Stringing,"



**Sketch of Bridge—A, showing where cut with Saw; B, where cut with Chisel; C, how Hitch Pins are arranged on Bent Side; D, how Trichord Notes are formed.**

in No. 41 of WORK, you will see why two rows of pins are needed for the trichord. If you cut a small piece of wood, and make the lines on it as described, you would soon see how the bridge is carved. The bridge is cut away on the bevel towards the sound-board, to free the string up to the bridge pin-holes. The string must be free between the bridges, from pin to pin.—T. E.

**Charcoal Furnace.**—T. J. W. (*Stoke Newington*).—According to your sketch the charcoal *ought* to burn. There are two things that might hinder it: one is that the whole thing is too small to burn, as you can only get a small quantity in—scarcely enough to keep alight; the next thing is that a solid bottom would be better than bars in this case, and cut a little off the bottom of the door for draught, or punch some holes in it. You ought to use very small pieces of charcoal, and light it before putting in; but if I were you I should use a spirit-lamp. You would get more heat from it, and it would be constant as long as the spirit lasted.

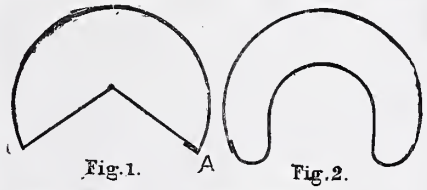


Fig. 1. Fig. 2.

**End Sections of Boiler for Model Steamboat.**

Your boiler is wrongly constructed. You have got most of the water at the bottom, where there is no heat. I send you sections of two boilers, either of which I have found to answer well. Fig. 1 is very simply made of copper, double-seamed and soldered at A, and an edge thrown off at the ends, the ends put on, hammered down, and well soldered. They will stand any amount of pressure that you are likely to want for model engines of any kind, and there is no fear of them leaking while there is any water in them. Fig. 2 can be made in the same way, but the working is a little more difficult. I hope that these few hints may get you out of your difficulty. If any further information is required, I shall be pleased to give it.—R. A.

**Pattern Cutting.**—A. M. W. (*Dublin*).—There is a book called "Last Fitting and Pattern Cutting," a modern (1885) treatise on boot and shoe manufacturing, by A. Hannibal, St. Bride's Avenue, Fleet Street, E.C.; post free, 3s. But I should think the one to suit you best would be (if you will allow me to judge for you) "A Manual of Boot and Shoe Manufacture," designed for the use of technical teachers and students, by Hill & Yeoman, and published as above; post free, 4s. I recommend this book because you also ask for a hook on the "technical terms" of the trade, and this one embraces not only pattern cutting, but subjects from the anatomy of the foot to prime costing; it also gives a good description of terms used in about fifteen subjects connected with the hoot and shoe trade.—W. G.

**Hand-sewn Boots.**—A. B. (*Manchester*).—Your first question is one that concerns almost everybody, for through want of knowledge in being able to judge a hand-sewn hoot from a machine-sewn, the public, by unscrupulous tradesmen and salesmen, are often greatly defrauded by the misrepresentation of goods. To answer this question to your, and my own, satisfaction, I should have to give one or two diagrams of sectional parts of boots of both makes, which would, with a proper description (which the subject deserves), make it too long for the "Shop" column. I will, therefore, as soon as time will permit, submit a short article on this subject for the Editor's kind approval. But, in the meantime, I will give you one or two hints that will help you in the matter. First take the sock out, and if you can see the stitches all round the inside, on the inner sole, you can be sure they are machine-sewn; if they are SMOOTH, they are either hand-sewn, standard-screw, or a combination. If they are standard-screw, you will find the marks on the inner sole of a small round disc. The screw wire is put in to such nicety that they seldom show on the inside, but if the centre of this impression is scraped away with the point of a knife, the brass screw wire will soon he brought to light and prove the make. Or they may be a machine-sewn welt (the nearest approach to hand-sewn), but in either case you may he ahle to see a real and good stitch all round the outside. Machine-sewn hoots or shoes are much heavier than hand-sewn. But another pretty sure guide is the inside of the heel, for as most all machine-sewn work has heels that are put on generally by a heeling machine, you can either see the heads of nails, or where they are clenched, on the inner sole of the seat, and if they are not machine heels they are nailed on by hand, and can be told in the same way: for this reason they often have a whole or half inner sole in them, hut if taken out it can soon be replaced. Hand-sewn men do not huild theirs in this way, for if not sewn they are pegged. Your second query, with regard to sewing the patch, see from A to B (Fig. 4), p. 201, No. 117, Vol. III. of WORK. You must not scrape kid, as that is a leather that has the grain side for the face. Calf you can, as the grain side is the wrong side, and the flesh the face. In answer to your third, I am pleased to tell you that my sixth paper, on Repairing, deals with welting and soling hand-sewn boots, which appeared on page 515 (No. 137).—W. G.

**Carriage Alarm Clock.**—ANSONIA.—I am afraid you will he unable to get the parts which you have broken and lost, as I have never been ahle to get exactly the same. The only thing I can advise you is to write to Grimshaw & Co., Goswell Road, Clerkenwell, London, and if they cannot supply you, then you can only put the remains aside as useless, or to come in for repairs, etc., to others of the same make; or you can write to the wholesale house of the company, or to the company themselves direct, and ask them to supply you with 'scape wheel, pallets and staff complete. I am sorry I cannot assist further, but they are made so cheap that it does not pay to stock parts.—A. B. C.

**Grandfather's Clock.**—P. R. (*Edinburgh*).—I am of opinion that you have either forgotten to put on the gathering pallet—that is, the little part that picks up the rack when it falls at the hour—or if you got that on (which fits on the end of a squared pivot of the wheel next ahove the wheel with the pins in it, and whieh lifts the hammer), you have not got the rack hook on—that is, the part that holds up the rack, or if on, it may not be working as it should; or, again, you may have it on all right, but, perhaps, the rack arm that rests on the snail, or should do so, may he hent out and falls ahove and over the snail, and so falls too far, and the gathering pallet cannot reach it to pick it up. See that all the ahove are right, that the rack does not fall beyond the reach of the pallet, and that the rack hook holds the rack up when it is gathered at the same time. Put the pallet on so that the hammer shall be free or off the pins when the tail of the pallet is resting on the pin in the end of the rack.—A. B. C.

**Chapel and Class-room.**—G. S. (*Glasgow*).—We cannot give contrihutors' addresses, but any stamped and sealed communication can be forwarded. Why not ask your questions through "Shop" for the good of the readers?

**Tar Stains.**—X. W. I. (*Portsmouth*).—The simplest remedy I can advise you to try would be to well wash the stains with spirits of salts well diluted with water. If this does not move them, try some quicklime spread over them thickly, like a paste, and left for twenty-four hours, the lime having been previously slaked with water to the consistency of cream. Whichever remedy you adopt, it must he *very thoroughly* rinsed off with water.—E. D.

**Core Box.**—G. B. E. (*Coseley, near Bilston*).—A paper on Helical Wheels is being prepared, and will be published shortly.

### III.—Questions Submitted to Correspondents.

**Brass Castings.**—Brass Finisher asks:—"Can any reader of Work tell me where I can buy a set of castings for a good brass fender and fire brasses?"

**Cement.**—Repairer writes:—"Will A. S. P. or others give a receipt for bicycle cement with proportions? I hear that old tires are used with other mixtures; what are the other things? I have some old rubbers."

**Wheat Mill.**—P. E. (*Cupar, Fife*) writes:—"Can any reader of Work give me a sketch of the cutters used for grinding coarse oatmeal? I have got a mill for grinding fine oatmeal, but find the same will not do for coarse oatmeal."

**Restoring Leather Chair Seats.**—Incrédule writes:—"Will A. J. (*Faversham*), who in p. 462, No. 133 of Work, recommends Jackson's varnish stains for above-named purpose, let your readers know where that material may be procured, as I would like to try it?"

**Banjo.**—Constant Reader writes:—"I am making a German-silver banjo; can anyone inform me how the edge is spun over the steel wires, also the easiest way of riveting it? I also want to engrave it. If any one of your readers can inform me the simplest way, he will oblige."

**Upholstery.**—W. W. (*Notting Hill*) writes:—"Will any reader give me some information how to stuff dining-room chairs, for I find when I make the roll and have stitched it, it is very uneven all the way round?"

**Whip Stand—Spring.**—Flagellum writes:—"Could any reader kindly give me an idea for a combination riding and driving whip stand? I should like it to be about 6 ft. high by 2 ft. 6 in. broad, standing on the floor against a wall, and containing a drawer for gloves, and so arranged that the riding whips might lie horizontally on hooks, and the driving whips might be upright. I should be glad to know, also, if there is any invention existing which is an improvement on the ordinary springs which are used for holding billiard cues, etc., in a vertical position in a stand, and which I find to scratch the cues, even if provided with rollers."

**Rope Door Mats.**—J. A. (*Southwark*) writes:—"Would any correspondent inform me how to make rope door mats? I have seen them oval shape, which I am told are made from old rope. I have pricked a hole through canvas and put the rope through, but it is not satisfactory. A rough drawing would greatly oblige."

**Wooden Horse.**—Old Chip writes:—"Could any reader tell me where I could get a wooden horse for a tricycle for a boy—a horse something like the hobby-horses we see going about?"

**Frames, Mounts, etc.**—T. B. (*Rochdale*) writes:—"Will any of our brother readers kindly give me the names and addresses of one or two wholesale houses in Manchester dealing in picture frames, mounts, etc?"

**Transfer Drawings.**—Draughtsman writes:—"Can any of your numerous readers give me any advice as to the making of transfer drawings for zincography? I use a crow-quill pen and Winstone and Sons' ink (litho transfer in sticks), but I do not know what consistency to make the latter. To get it a nice black I have to make it so thick that it will not work easily, and if I make it work easily the lines are faint in places. The crow-quills, too, seem to scratch up the surface of the prepared paper and blob the pen, making thick, smudgy lines where I want fine ones. The process is not photo-zincography, but the drawings are transferred direct from the prepared paper to zinc. I should be glad to know if there are any remedies for the defects I have mentioned, the best materials to use, etc., or if it is my own clumsiness."

**Exotics.**—Ajax writes:—"Can any reader of Work kindly inform me where to obtain any manual on the manufacture of artificial exotics?"

**Engine.**—Young Engineer writes:—"Will some reader give me a hint as to the colours to paint an eight-horse horizontal engine—such as cylinders, fly-wheel, and other parts? also colour for lining to match? Which kind of paint, too, ought I use to a ten-horse vertical boiler, or would gas tar do?"

**Fret Machine.**—N. R. (*Yeovil*) writes to W. R. S. (see No. 133, page 461):—"Kindly tell me how to make a fret-machine saw, to fix to a table or bench."

**Monogram for Fretwork.**—N. R. (*Yeovil*) writes:—"Will some kind correspondent give me a NR monogram for fretwork?"

**Chuck.**—Young Turner writes:—"Would any kind reader tell me how to make chuck, for oval turning out of wood? If Mr. Blackett could give me any information I should be very much obliged."

**Cement or Glue.**—J. H. P. (*Blackpool*) writes:—"I want to make a flexible waterproof cement, suitable for applying to leather. The cement must stand 130 deg. Fahr. of heat without softening. Can any readers of Work assist one in a fix?"

**Paraffin Oil Stove.**—Solder-Pot writes:—"Can any brother reader inform me if a plumber's metal-pot and solder can be heated by paraffin oil?"

**Spirit Stand.**—Carr Dyke writes:—"Can any reader of Work give me a design, or particulars as to where I can get fittings for spirit stand?"

### IV.—Questions Answered by Correspondents.

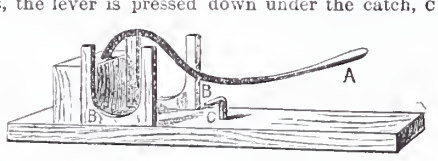
**Locks.**—Brass writes that if J. G. (*Bloomsbury*) (see No. 134, page 478) will apply to the undermentioned, he will in all probability get what he requires:—Mr. Wakeman, St. John's Square, E.C.; W. Taylor, Tower Street, E.C.; Thos. Ray, Waterloo Road North; all of Wolverhampton.

**Model Steam Launch.**—R. R. (*Liverpool*) writes, in reply to A. M. C. (*Holywood*) (see No. 135, page 494):—"I should advise you to write to the engineering firm, Leop. Tolch, of Liverpool, who will give you every information about launches. The above firm are supplying also petroleum launches (pat. captain), which have met with general approbation, and have been considered even better than steam launches."

**Wood Mole Traps.**—J. T. and Sons (*Ulverston*) write, in answer to J. J. (*Cumberland*) (see No. 135, page 492), that they "make them one of their leading lines."

**Heating Room.**—H. J. L. J. M. (*Ealing*) writes, in reply to C. J. P. (*Derby*) (see No. 133, page 462):—"I should think that for a room of the size you name (8 ft. by 5 ft. by 9 ft.) the duplex burner, if lighted an hour or an hour and a half before you require to use the room, would give out quite sufficient heat. I saw a lamp the other day called 'Lampe Veritas,' which gave out, according to size, twenty-five or fifty candle power. It was so arranged that the lamp could be placed in a radiator of cast iron for warming purposes, or put on a table for lighting purposes. This lamp is extensively used in country places for warming and lighting purposes. I should avoid the quicklime plan: it is used by workmen in the open air, but I should not like to try it in a room so small as described by C. J. P. It may be well to advise C. J. P. to see carefully that his room is suitably ventilated, or his studies may suffer and himself too."

**Firewood.**—F. H. (*Streatham*) writes, in reply to F. B. (*Rochdale*) (see No. 134, page 478): "I have sent a sketch of a simple firewood bundling machine, which I hope will be plain to F. B. A is an iron lever; when the wood is put into the round bars, B, the lever is pressed down under the catch, C;



Machine for Bundling Firewood.

a counter weight or a spring will bring the lever up again when the bundle is tied. In Vol. I., No. 11, page 171 of Work, under the heading, 'Our Guide to Good Things,' there are illustrations and description of 'Machinery for Splitting and Bundling Firewood,' which I am sure will be useful and interesting to F. B."

**Paper for Stencil Plates.**—G. P. (*Elgin*) writes:—"In Work, page 459, Vol. III., I see a reply under the above heading by S. W. I do not think S. W. will resent my sending the following: I have no wish to contradict him in what he says, for the simple reason that I couldn't, but I believe that the substance I am about to name is better than either of those which he suggests. This material is Willesden 1-ply paper. It is a thin substance, although it possesses good body, and is by no means easily torn; it is easily cut, and it does not absorb much moisture. It is to be had from the Willesden Paper and Canvas Works, in various colours at various prices."

**Coating for Damp Walls.**—G. P. (*Elgin*) writes:—"Under the above heading The Author of 'Every Man his Own Mechanic' recommends R. A. P. to use a solution of naphtha and shellac (see No. 133, page 462). Now, without going to contradict such a high authority, allow me to suggest a material which may be used without the unpleasant smell of the naphtha solution. That material is Willesden paper. All substances which have been used as lining papers for walls where damp would be likely to injure the paper have been superseded by this paper, which is made by the Willesden Paper and Canvas Company, and is much cheaper. These papers may even be used by themselves, being supplied in certain colours, besides admitting of being coloured. For lining damp walls, either the 2-ply 54 in. wide, at 1s. per yard run for brown, 1s. 4d. for neutral green, and 1s. 6d. for extra brown; or the 1-ply 56 in. wide, at 6d. per yard run for brown, 9d. for extra stout, and 8d. for neutral green, is recommended. I derive no benefit whatever from thus bringing the paper under notice, except the satisfaction I feel from letting others know of a good thing."

### V.—Letters Received.

Questions have been received from the following correspondents, and answers only await space in Shop, upon which there is great pressure:—J. H. (*Manchester*); R. T. (*Paisley*); W. G. S. (*Manchester*); Cycles; A Reader; J. T. (*London*); H. S. G. (*Fulham, S.W.*); R. H. H. (*Merriols*); M. D. C. (*Liverpool*); Lux in Tenebris; F. W. (*Kingsland, N.*); Markwell; J. J. M. (*Liverpool*); Centre Board Canoe; Bellows on Three Legs; R. M. B. (*Glasgow*); G. W. (*Chelsea*); W. J. (*Heaton*); W. P. (*Withington*); Gum; A. B. G. (*Ascot*); A. T. L. (*Gloucester*); A. M. L. (*Nuneaton*); J. E. (*Cardiff*); Leghorn; H. B. S. (*Liverpool*); A. H. (*Hyde*); A. N. (*Bexhill*); Grindingstone; New Reader; Stonemason; J. C. F. (*Coalbrookdale*); J. C. K. (*Lisson Grove*); Lance Jack; H. B. (*Accrington*); G. H. (*Leith*); R. T. (*Oldham*); W. R. W. (*Fulham*); W. J. H. (*Reading*); One in a Fix; W. H. S. (*Birmingham*); Knarf.

## MANUALS OF TECHNOLOGY.

*Kindly mention this paper when ordering.*

Just published, price 4s. 6d.

## A First Book of Mechanics for Young Beginners.

With numerous Easy Examples and Answers. By the Rev. J. G. EASTON, M.A., late Scholar of St. John's College, Cambridge, formerly Head Master of the Grammar School, Great Yarmouth. Fully Illustrated.

The present work has been developed from notes compiled by the author during a considerable scholastic experience, for the use of pupils preparing chiefly for the London Matriculation, the Preliminary Medical Examination, and the additional subjects of the previous Examination at Cambridge. In its present form it is intended to supply the want, which has probably been often felt, of a text-book on mechanics, treated with mathematical strictness, and suitable for beginners whose mathematical knowledge is limited to Euclid's Geometry and to Algebra as far as Quadratic Equations.

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London.*

**FLUID WATER RESISTING GLUE** (*Patent*) PATENT TINS.

## SILICO ENAMEL

SAVES CLEANING & POLISHING

SILVER, PLATE, BRASS, STEEL, &c.

"SILICO" is a thin liquid enamel, finer than varnish, easily applied to all polished metals, dries in a few minutes, and forms a smooth invisible film that not only protects the metals from rust or tarnish, but preserves the brilliant appearance. It will not injure the richest metal, and can easily be removed if desired. As supplied to Government, Museums, etc.

Bottles with brush, **1s.**, from Cycle Depôts, Ironmongers, Stores, &c., or post free from

**SILICO ENAMEL CO.,**

## LIGHTING ARRANGEMENTS IN TEMPORARY DECORATION.

BY ARTHUR YORKE.

PRELIMINARY REMARKS — A CANDELABRUM — CHANDELIERS — A SCONCE — IMPROMPTU CANDLESTICKS.

*Preliminary Remarks.*—When, on festive occasions, some ordinary building is under conversion to the uses of a temporary ballroom, concert-room, etc., there is among the resources of the decorator one which might well be more freely employed than it is. The resource alluded to is rustic carpentry, for the production of frames to be afterwards dressed with evergreens and flowers. Such dressings, when judiciously disposed on wood-work covered by its natural bark, have a most happy naturalistic effect, which can scarcely be imagined by those who have not seen it.

For mere temporary uses frames of this kind can be quickly knocked together, and in country places, where natural wood is to be procured readily, these things may be made at trifling cost. The purposes to which they can be applied in such decorations are various, but in the present paper it is proposed to deal only with their application to lighting.

The examples given in the illustrations may perhaps be thought to be less ornamental than they might be, but it must be remembered that they are only skeletons

depending for their full effect upon the flowers and greenery with which they will be clothed.

*A Candelabrum.*—The candelabrum shown in Fig. 1 is an arrangement which may be found useful when the main room is approached by a tolerably wide passage or ante-room. Such candelabra should, of course, be arranged in pairs. The example given shows only three lights, but if there is width sufficient, and it is desired, one or two more branches may be added. The stem is made from the trunk of a young fir or from the top of a larger tree; and to secure a firm base, its bottom is mortised into a heavy slab of wood. The appearance of this slab is of little moment, as it is intended to be covered with evergreens, from which sprays of the small tree ivy should spring and twine spirally round the stem. In decorating the branches above, flowers should be used with the greenery; dried everlasting flowers of various colours are best for the purpose, as warmth will not fade them, and a thin wire run up their stalks will facilitate arranging and keeping them in the positions desired. In this merely temporary wood-work no hesitation need be felt about driving a tack wherever it may be desirable to hold the wreaths, etc., in place, which is a decided advantage to the decorator.

*Chandeliers.*—Figs. 2 and 3 are chandeliers; Fig. 2—which appears in plan in Fig. 4—is of most simple construction. It consists of two straight sticks (fir by preference) cut half through to cross each other in the centre, and with their ends sawn V-shaped to receive the upright pieces (A, A, Fig. 4), which are nailed to them, and which support the candlesticks. It is suspended by four cords or chains attached to staples driven into the cross-pieces (B, B, Fig. 4). When decorated, a considerable bunch of evergreens—holly, perhaps—will look well hung beneath the middle, whilst small and delicate sprays should be made to twine up the cords.

Fig. 3 is somewhat more ornate. The four pieces which form its branches are such as in general shape it is easy to find among a lot of crooked wood—oak, say, or apple-tree. It is recommended that these should rather be screwed to the upright than nailed in the usual way. At bottom, a fir cone is introduced as a pendant, and will best be fixed on with a couple of wire nails. The branches in this should not be heavily decorated—a little green only, with some flowers—but more evergreens will look well up the central stem; in particular, they may be made to branch out round the ring at top.

*A Sconce.*—The shield of the sconce given in Fig. 5, and in profile in Fig. 6, is of rough board, and has a hole bored through it at C, by which to hang it up. How rough the board may be matters little, as laurel or other large evergreen leaves should be tacked over the whole of it. The projecting branch should be decorated with a sparing hand.

*Impromptu Candlesticks.* — The candlesticks which will suffice for use in these temporary arrangements are of a kind which any handy person can readily improvise with no further tools than a bradawl and a pair of zinc shears: which are tools that no handy person is or ought to be without. As material, old meat tins will be found sufficient. Fig. 7 is a section of one of these candlesticks. A disc of tin 3 in. or 4 in. in diameter is cut, and bent to something of a saucer shape; two strips of the same, about ¾ in. broad and 2 in. long, are also prepared, and bent as in Fig. 8. These are then placed crossing each other, and laid on the middle of the disc, and a hole is punched through the three thicknesses. Through this hole a ½ in. tack is thrust, point upwards, as shown in Fig. 7. This forms a spike, which, entering the bottom of the candle, helps to steady it; for it must be remembered that the upturned pieces of tin, though they act as springs and grip the candle tightly, are less strong than a circular socket. The candlestick is fixed down to the wooden support by other tacks round the central one, as shown.

In these arrangements only the simplest and prettiest mode of lighting — that by candles—has been considered; but if space permitted, it would be easy to show how, by the same means, we might provide for the use of paraffin lamps, either to hang or stand. For standing lamps, rustic brackets would have to be arranged instead of sconces. These and other necessary modifications will, however, readily suggest themselves to the ingenious reader.

## PLUSH-COVERED FRAMES.

BY D. DENNING.

ADVANTAGES OF PLUSH—MATERIAL—MOULDINGS—ADHESIVES—MODE OF APPLICATION—FOLDING AT CORNERS—DECORATION OF CORNERS—COMBINATIONS OF PLUSH—STUDS—HINTS ON COLOUR — PLUSH-COVERED CHIMNEY-GLASS FRAMES.

To make an ordinary frame for a picture is by no means a difficult matter, though great neatness is required at the mitred joints. To cut these correctly, however, requires some experience, and more skill than the amateur, with often only a very limited amount of time at his disposal, can always acquire. No doubt, therefore, a few suggestions as to the way in which the difficulty may to some extent be surmounted, or perhaps I should rather say, evaded, and a good-looking frame be made—even though the joinery be anything but neat and clean—will be welcomed by many readers.

As the head-line indicates, the unsightliness of a badly-made joint may be hidden by covering it with some textile fabric, and the one the following remarks have special application to is plush. I hope it will not be understood that there is any special advantage in having the mitres for these frames badly made, for, on the contrary, it will be to the worker's benefit to make them as carefully and neatly as he can. The frame, when finished, may not look any better than it otherwise would if the joint were a rough one; but the fact of trying to make it as well as possible will give experience which may come in useful later on. To attempt to work valuable mouldings without any preliminary practice in frame-making would almost certainly lead to waste, and possibly to discouraging disappointments. By beginning with cheap mouldings, and covering them afterwards either with plush or other suitable materials, not only need there be no waste in tentative efforts, but the knowledge gained will pave the way for more advanced work.

I do not, of course, advise that large frames should be made for covering with plush, but small ones for photographs, engravings, etc., may be made in almost endless variety. Even a plain rectangular frame looks well, and great variety can be got by using coverings of different colours.

The plush best adapted for the purpose is the ordinary silk velvet, which is sold by drapers for ladies' dresses, etc., and by upholsterers for draperies, chair-seats, etc. Remnants can occasionally be purchased at a very much lower price than when cut from the piece specially, and, unless the pieces are very small, they do just as well. The coarser velvets—such as mohair—are not suitable for small frames, but if silk plush is asked for there will be no difficulty in getting the right kind. When of the best qualities, it is rather expensive stuff, so care should be taken to cut it to the best advantage, and keep the waste as trifling as possible. On this point, however, it is impossible to say anything definite; but it may be suggested that it is rarely considered necessary to use the best quality for such frames as are referred to.

The foundation or wood-work of the frame being hidden, there is no necessity for wasting much time in carefully finishing it or in having it the best of its kind. Plain beads or flats even do very well, and should they be a trifle rough it will hardly matter, as, unless very pronounced, the inequalities will not be visible under the plush. If a more elaborate moulding is desired, those made and sold at a very cheap rate for builders' purposes do as well as anything. It is not necessary to clean them down with glass-paper. They can be covered just as they are received. Many mouldings which may look very well when uncovered do not show to the best advantage when covered with plush, and when selecting them, some discretion should be used to get those which will look best when finished. Perhaps my meaning may best be explained by supposing a moulding formed of a number of small members. This would look richer than, say, an ogee or a plain bold moulding while uncovered, but the small details in which its beauty consists would be almost, if not entirely, hidden by the velvet. This, though on the back it might adhere to them closely—not at all a likely case with such a moulding as is supposed—would on the front or plush side only partially reveal the shaping below. The chances, therefore, are that a plain moulding will look equally as well as one of a more elaborate character.

About the actual construction of the frame little need be said, as for present purposes it may be supposed that the intending worker has some knowledge of this part of the work. In most cases plain mitred joints will be the natural ones to use, and where any others are preferable, the worker may be safely left to use his own discretion. If he makes them strong enough for their purpose, and does not overlook the fact that they are covered over afterwards, he will hardly be likely to err.

As plush is a delicate material, care must be taken, when handling it, not to get the surface matted or injured with glue or paste. If any of this gets on the front, it will be difficult, if not impossible, to remove the blemish. Care, therefore, should be taken in this respect. For the rest, plush will bear any reasonable treatment. Some of the lighter and more delicate tints are very easily soiled, but by taking the precaution to have the hands clean, there is no risk on this score. The chief danger the novice should be on his guard against is that of getting the plush matted anywhere by allowing the glue to soak through from the back. If he will do as directed, he need have no fear of this happening.

The glue should, in all cases, be applied to the wood, and never to the velvet. Good ordinary glue can be used, and I know of nothing better, though a mixture of flour,

paste, and glue, or any strong paste—such as used by bookbinders, shoemakers, etc.—is preferred by some. Any good strong adhesive which has not too much moisture, and which does not set so rapidly as to prevent the velvet being laid properly, may, in fact, be used. There is thus plenty of choice; but, as stated, I think there is nothing better than plain glue. It should be of good quality originally, be prepared in the usual way, and be applied, while hot, thinly and evenly to the wood. While it is still sticky—*i.e.*, as soon as convenient without either undue hurry or waste of time—the velvet should be put on.

This is really the only part of the work which requires any unusual amount of care, for if any glue gets on the fingers, and from thence to the plush, a blemish will be caused, which will look anything but nice when the frame is finished. Great pressure is not necessary to cause sufficient adherence. If it were, the plush would be spoiled through the glue being squeezed through the woven backing. A light gentle pressure is all that is required, though possibly the velvet may require a little humouring to get it to fit into angles. When these occur, it is sometimes easier to use a paper-knife or something of the kind to press the velvet neatly into them. Of course, the pile will be somewhat laid or flattened by this treatment, but unless the glue has been forced through, it will be only temporarily so, and can easily be restored to its original condition by brushing lightly with a soft brush.

At the mitres and outer corners of the frame a slight difficulty may occur to the novice in connection with folding the plush over the edges. Special care is necessary—or perhaps I ought to say neatness and deftness—in manipulation at the angles if, on the one hand, a vacant uncovered portion of the wood is to be avoided, and on the other, a wrinkle in the velvet. Both these effects may easily be prevented by cutting the material as far as the front surface of the frame, and cutting away as much as may be necessary to allow of a neat join being effected. As I was on one occasion asked if the velvet was to be sewn at the joints, I may as well say that glue alone is necessary. The velvet is simply stuck to this, and when neatly done, the join is almost invisible, except on the closest examination.

On the inner edges of the frame, if they are only thin, no difficulty will arise, as after cutting the velvet up to the mitre, it easily folds over to the back, when, of course, it can be fastened with glue. The outer edges should also be covered, and the plush be secured behind in the same way.

So far it has been assumed that the frame has been covered with one piece of velvet, from which a portion in the centre has been cut out to correspond with the frame opening. This is all very well for small frames, but if these are of any considerable size, there must obviously be a waste of plush, which would not occur if the frame were covered by pieces cut to fit each portion. This can easily be done by cutting the plush to strips of sufficient width to cover the front of the moulding, and having enough margin to turn over and secure behind. One strip will, of course, be used for each side, top, and bottom of the frame, for a join anywhere, except at the corners, is out of the question.

At the corners the velvet must be cut to correspond with the mitres, and if this be neatly done, the join will hardly be more perceptible and not more unsightly than a properly made joint in the wood. To cut the pieces of velvet so that they join with such accuracy as is implied may not, however, always prove an easy task, but if they do not meet, there is always a simple way out of the difficulty, and the means used, instead of being a disfigurement, may often, with a little taste, be rendered a further source of ornamentation to the frame.

The simplest means of covering the join is using a piece of fancy cord, such as is used by upholsterers for trimming purposes. Its ends are fastened behind, and if the moulding is a plain one, it is merely carried over the joint, which of course it covers. If the moulding is a large one, and has any decided hollows, there will be a little more difficulty, but not much. Sufficient adherence can be given to the cord by touching it here and there with a little strong glue, or if this is not sufficient, by means of a few gimp pins driven through it into the wood. The heads of the gimp pins, being small, can be concealed by a strand of the cord.

In a similar manner the joints can be covered with narrow bands of plush or any material which will look well with it. The ends, as before, are fastened on behind, and the edges, being turned under the band, can be fastened down with glue. It is not necessary to have these small covering pieces of the same colour as the other plush, or, as has been hinted, even of this material, but care should be taken that they are harmonious.

Instead of a plain band to cover, if the moulding is a large one, much taste may be displayed in the arrangement of the pleats which can be given to them. Though it is obviously impossible to do more than hint at this additional method of adornment, there is an immense field open for the worker to display his taste.

Very handsome frames may also be made by the judicious use of plush in a more elaborate style than that which has been referred to. The possibilities comprehended by it as a material for frames are much greater than is commonly supposed for them, for there is no reason, beyond custom, why it should not be used in the construction of frames of an elaborate character much more extensively than it is. We may, for example, suppose a wide frame of the simplest kind—merely a wide flat. This, covered with velvet, would look well enough, and I have nothing to urge against it. Something more elaborate, however, may be wanted than the plain flat surface; and how easily it can be managed! We take a narrow piece of half-round moulding, cover it with velvet of another colour and a suitable one, glue it down on the flat, and there is already the germ of an idea which can be worked on to an almost unlimited extent.

Starting again with the flat, another piece covered with velvet can be fastened to the outer edge, an inner flat can be made to fit within the other, and so on. An almost endless variety of combinations might be suggested, and no doubt will occur to the novice as his experience widens.

Another very simple means of decorating velvet-covered frames is by means of the plain brass or copper studs now so extensively used by upholsterers round chair-seats, etc. The studs can be either driven in close together in straight lines or arranged so as to form simple patterns—such as diamonds, circles, etc.—on the flat surface, and on a velvet of suitable colour look remarkably rich.

Perhaps it may be expected that something should be said about the colouring or combinations of colouring which have been suggested, but if so, I am sorry readers must be disappointed, for the subject of harmonious blending of colour is altogether too vast to be undertaken in the compass of a short article like the present. All that can be done is to throw out a hint or two for the guidance of the frame-maker.

Primarily, a frame is intended to hold something. If this is a coloured picture, take care that the colours of the velvet are not such as to kill the colouring of the picture. If the frame is more striking to the eye than the picture is, there is something wrong. Strong powerful colours in the frame may overpower those in the picture, and if so, the decoration of the frame fails in its purpose.

In the case of monochrome pictures, such as photographs, engravings, sepia drawings, and such like, the same rule holds good. Those who have paid little or no attention to colour from a scientific or artistic point of view may easily try a few variations for themselves on the lines suggested. Black and white placed in juxtaposition, everyone, it may be assumed, knows intensify each other. In a similar manner, other colours may be arranged to "show each other up." This should be the object of the velvet frame maker. Let him select colours which will show up whatever is in the frame.

Due attention should also be paid to the colour of the wall on which the frame is hung, to that of the draperies of the room, and so on. When selected with skill, charming bits of colour may be got without much effort; and by converse, the appearance of a room may be almost spoiled by inharmonious colourings. Whether these be bright or low in tone, the rules which govern them are the same; but, as I have said, the subject cannot be treated of at length here.

In conclusion, it may be suggested that many a chimney-glass frame of the gilt and gaudy kind may be vastly improved by covering it with velvet in a similar manner to that alluded to for small frames.

## THE SAFETY BICYCLE: ITS PRACTICAL CONSTRUCTION, ETC.

BY A. S. P.

FINAL RE-FITTING UP—ADJUSTING THE BEARINGS—HANDLE-BAR—FIXING ON THE HANDLES—REAR-WHEEL, MUD-GUARDS, ETC.—ADJUSTING THE CHAIN—ADJUSTING THE SEAT—ADJUSTING HANDLE-BAR AND BRAKE—ADJUSTING FOOT-RESTS—ACCESSORIES—HINTS TO CYCLISTS—CARE OF MACHINE.

EVERYTHING being ready for the final fitting up of our machine, a piece of carpet or canvas should be spread on the floor, so that the enamel or nickel-plating may not suffer damage.

The first thing to do is to fit the spoon on the front fork, then spring in the wheel. Some front fork ends are slotted through, so that the axle drops into its place without springing the forks at all. If the forks are to be sprung in order to admit the axle, see that the latter is no longer than just to come through the outside nuts, because it is quite possible to overstrain the forks trying to enter a long axle. See, also, that the loose or running cone is on the left-hand side. Before springing in the wheel, this cone should be screwed up till it jams the balls—in other words, till it stops against the balls; then it should be turned back, say, one-fourth of a turn, or as much as will allow the wheel to run perfectly free without side shake. While in this position,

put it into the fork, put the mud-guard stay ends on the axle, and screw up the nuts. The wheel, if it has been properly fitted the first time, should run exactly in the middle of the fork space, and directly under the brake-spoon.

The handle-bar comes next: but we have got to fix the handles to it. The handles may be horn, rubber, or cork; in either case they are fixed on with a little of the cement used for the tires. Our handle-bar is $\frac{3}{4}$ in. tube throughout, so that the handles have $\frac{3}{4}$ in. holes quite through them. Heat the handle-bar end in a gas-jet, and having melted a little of the cement, give the hot end a thin coat for about two inches of its length, then slip on the handle, pushing it up till the bar just appears at the outer end. When this is hard it will be impossible to take the handle off again without heating. It sometimes occurs, however, that a handle is wanted off; to do this, heat a bit of flat iron to red, and place the handle-bar on it nearly close up to the handle; when the bar is heated the cement will dissolve, and the handle may be easily slipped off.

Leaving the handles to cool, put the two parts of the frame together by passing the steering-tube up through the steering-head, then slip on the adjusting cone; after this, the lamp-bracket. Now the handle-bar is put into the steering-tube; see in setting it that it is square across the wheel, and pinch it, meantime, with the set-screw. The brake-lever and other parts of brake-work are now fitted; then turn the machine over with the handle-bar on the ground, and put the rear wheel in its place, the V part of the frame having previously been fitted to the central part, the upper bolts of the lower tubes put in, and the mud-guard fixed behind the bent tube. Now push the wheel to the inner ends of the slots, put on the four stay ends, and screw up the outside nuts. The bottom bracket bearings being mounted and adjusted on the pedal-shaft, the whole is fixed in the bracket-fork by the two long bolts.

Now the chain is put on, see that the head of the small chain-bolt, or the nut, as it may happen, is quite clear of the spokes, as in some makes of hubs it is not. Now slacken the outside nuts of the rear axle, and push the axle back with the two adjusting screws, taking care that both sides are pushed equally, so that the tire of the wheel may be in the centre of the space allotted to it; continue the adjustment till the chain is almost tight. It should hang curved about half an inch or more. If it were adjusted to tightness a good deal of friction would exist, and the grand object in a cycle is to get rid of friction by all possible means. Having fitted up the L-pin, saddle and spring, and the pedals, you are now in a position to adjust the seat and handles to your requirements as a rider. If you are a cyclist, you will know that when mounted you should be able just to place your foot on the pedal at its lowest point with the leg quite straight.

The saddle-clamp should be midway in the length of the three-coil spring, and the lower plate should be clamped also at its centre by the bracket (Fig. 37, page 436), then the whole is free to move on the L-pin for adjustment to fit the rider. The saddle being placed to proper height, the handle-bar may be raised or lowered till the handles are about three inches higher than the top of saddle, when it is fixed in the steering-tube, and the brake-rod at the same time fixed with the gripping end of the brake lever at its lowest, and the spoon half an inch clear of the tire. The brake-lever requires a spring of some sort to lift the spoon clear of the wheel; steel springs between the lever and the handle-bar are sometimes used, but they are seldom effective for any length of time. A spiral spring is often put on the brake-rod; in our case it can be put on the rod in the space between the lamp-bracket and the top of the rod, at D (Fig. 35, page 436). This spring should be plated. The simplest and always effective spring is a rubber band encircling the handle-bar and brake-lever just at the end above the brake-rod; when one is too weak, two can be put on. If adjustable foot-rests are used, they are put on at a convenient height for the feet to rest without outstretching.

Now we may say our machine is completed, and after it is furnished with a lamp, a bell, and a tool-bag, it will appear as represented in the illustration accompanying this—the closing paper on this subject. The latest style of lamp is known as the "swing-back," the aim of its construction being that it will have a certain amount of spring while the machine may be passing over rough road, so as not to jolt the wick down. These lamps may be bought from 4s. or 5s. up to 15s. Cyclists are compelled to carry lamps after dark by law. The bell is a necessity as an accessory. There are several kinds. The double dome, at 5s., is very good; single dome may be bought for 2s. 6d. The horn is about the latest fad; I can recommend it for ugliness, but for nothing else.

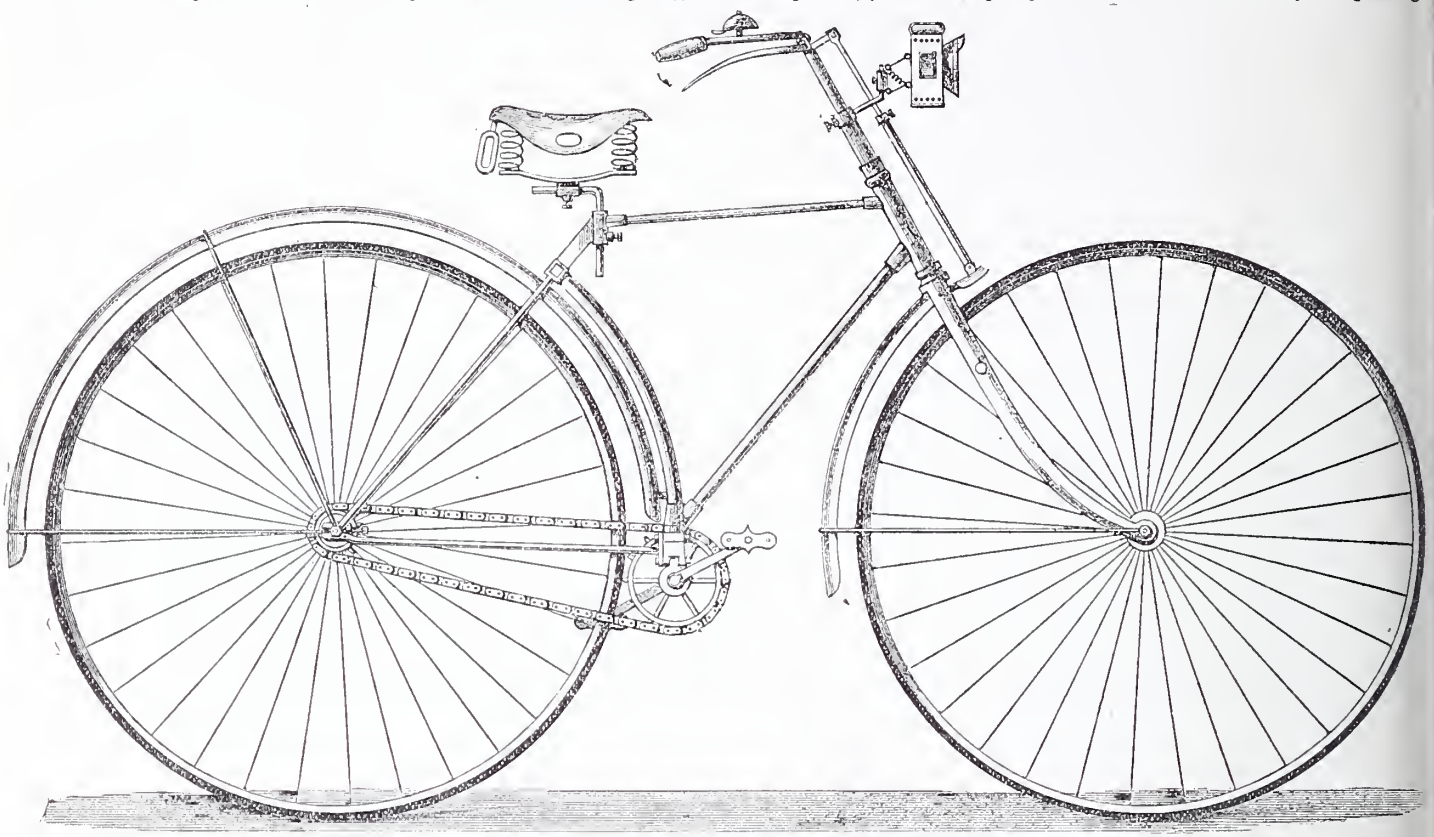

Fig. 44.—The Safety Bicycle, complete and fully fitted for the Road. (Scale, $\frac{1}{10}$ full size.)

The tool-bag is usually strapped on behind the saddle. It may be had from 2s. upwards. It is furnished with a spanner and oil-can.

We have now to offer a few hints to cyclists in general with regard to the care and keep of their machines; for it is a fact that many are the possessors of safety bicycles, costing from £15 to £20, who are almost totally ignorant of the nature of their mechanism.

The vital parts of a safety bicycle of the first class are the ball bearings. These are entirely concealed, and in many cases the possessor of the machine knows absolutely

nothing of their properties, or of the means to get the best results of their use: whereas if they knew but a little how to adjust their bearings—which is usually a very simple matter—they would be saved many a trip to the repairing shop. To all such I would say, invest a penny weekly on WORK, and read these papers carefully, and you will know all that need be known about the matter, as well as most other matters connected with the machine. I have tried all through to state things clearly, and wherever it is found I have failed, I will be glad to know of it through "Shop."

With regard to the keep of the machine, any mud should be washed off after using. To keep the plating bright, by all means keep it dry, drying it carefully after being out in rain. It may be made to shine by using jeweller's rouge made into a paste with water, and applied with a bit of chamois-leather, then wiped off and polished with a larger leather. If the machine is to be laid by for the winter, or even for a short time, where there is danger of damp, all plated parts, including pins, bolts, and nuts, should be well coated with vaseline. This may be wiped off when the machine is to be used, and the plating will be found to be bright and good.

To clean the bearings of the wheels and pedal-shaft after the machine has been used, the best plan is to take down the bearing, keep the balls in paraffin, and clean out the cases with the same oil. If you do not care to take down the bearings (which means taking the wheels out of the frame), turn the machine on its side and run plenty of paraffin through the bearings, revolving the wheels rapidly. This will wash out most of the dirt. After this, wipe the machine clean, and oil up with good cycle oil. About as good as is going is six parts of best sperm to one of paraffin; the paraffin thins it and prevents clogging.

To clean the chain, remove it from the wheels, and placing it in a shallow flat-bottomed pan, cover it with paraffin; let it remain an hour or two, then wipe with cloths. All chains should be lubricated along with the wheel teeth. Oil is very good if the roads are free of dust; on dusty roads, however, the chain is soon coated with it. A preparation of blacklead is used instead of oil for chains, and does not lick up the dust as oil does, and is, therefore, preferable on dusty roads.

Cyclists while on tour should always be provided against tires coming loose. Pieces of string or wire are useful; but there are several sorts of tire binders or fasteners in the market that the cyclist should not set out without.

It is no uncommon thing for a nut to drop off a machine and get lost, and sometimes a single missing nut will disable the machine for the time being. Every owner of a machine should find out the size and thread of all nuts on his machine that are at all likely to work loose and get lost, and provide himself with at least one of each size. They are easily carried in the pocket or tool-bag, and as he always has (or always should have) a spanner—one that will adjust to fit every nut—on finding a nut gone, he has nothing to do but broach his store, replace the nut, and go on his way rejoicing; whereas the fellow unprovided with nuts has, in like circumstances, to trundle his machine, perhaps miles, to the nearest wayside smithy.

Spokes often work loose, especially if they have been rather easily tapped when made. When this takes place the wheel begins to wobble. If cyclists would, therefore, learn the use of the spoke-grip, they would often save their pockets by doing themselves what they have to get done by a repairer. The spokes, in such a case, have simply to be screwed home to their former position. Ample directions are given in their proper place in this series: "How to True a Wobbling Wheel," so they need not be repeated here.

With these remarks on the care and keep of machines, which are meant for all cyclists who may read them, and to whom they may be information, I bring my present task to a close, in the sincere hope that the information sought to be conveyed will be found useful to many readers of this Journal, whether they put it to practical use or not; and I would respectfully ask readers who may find them interesting to draw the attention of their friends and acquaintances to their existence in our excellent weekly, WORK, thereby increasing the usefulness of that already useful publication.

## A LAMP FOR A MAGIC LANTERN.

BY THOMASO.

I AM warned that answers in "Shop" must of necessity be brief, and as brevity to meet the needs of "Shop" is not to be achieved in giving the information that "Pedagogue" seeks, I am compelled to put it in the form of a short article.

The querist says his lantern does not give a sharply defined picture using a duplex lamp. Is he sure the light and reflector are in their right places, and that the diaphragm in the front lens is properly placed, and the aperture of the right size? This latter is probably the cause if he made the lantern himself. The lamp might cause an unevenly lighted or dull picture, but I do not see how it could cause a blurred picture—for it is thus I read his letter. However, I assume that he is satisfied it is the lamp in fault, and accordingly give a description of a three-wick lamp. Two wicks are used placed thus: V, with the point of the V towards the picture. Four and, I believe, five wicks are used, but they do not give much more light than three, and the extra heat is a serious matter. "Shop" space is limited, so must my instructions be. Take great pains to get everything true and square, or the lamp, if it burns at all, will either stink or smoke—perhaps both. Cut all holes in sheet-metal with fret-saw, to prevent buckling. Use the "Russian" sheet-iron (ask for best charcoal-iron) and the best tin plates (not "wasters"). Get some $\frac{1}{8}$ in. tinned iron wire, and some a full $\frac{1}{16}$ in.; brass plate, $\frac{1}{16}$ in. and $\frac{1}{8}$ in. Flat brass wire can be got these thicknesses, $\frac{1}{2}$ in. and $\frac{3}{4}$ in. wide respectively. Fig. 1 gives view of lamp complete, with dome raised exposing wicks. Make the dome of sheet-iron, 6 in. long from end to end, and of the other dimensions shown in Fig. 2, which is half full size. Wire ends with the thin wire, bend dome to shape, and then run a wire round bottom and across ends, allowing wire to project $\frac{1}{2}$ in. in front. A hole, $3\frac{1}{4}$ in. by $1\frac{5}{8}$ in., having been previously cut in top, a piece like Fig. 3, $1\frac{1}{4}$ in. high, is riveted in. Upper edges of this are turned inwards and flattened down for strength. Bend another wire same shape and size as that on bottom of dome, and on each side fix a strip of tin of shape shown in Fig. 1 by bending top edge of tin round the wire. The holes in the strips are necessary for ventilation.

Now make burner. Wick tubes $2\frac{1}{2}$ in. long ($1\frac{1}{2}$ in. wick should fit easy), made in two pieces (Fig. 4 is section; observe how ends lap). Cut two holes in one side of each tube, $\frac{5}{8}$ in. apart, and $\frac{1}{4}$ in. by $\frac{1}{8}$ in. for the wheels to wind up wick. Make a piece of tin for each wick tube of shape shown (A, Figs. 2 and 5, complete arrangement). Cut out little wheels in the $\frac{1}{16}$ in. brass like Fig. 6. (*Nil desperandum;* I once made a dozen by hand.) Drill the central hole first, and then file teeth. Cut piece of thick wire any

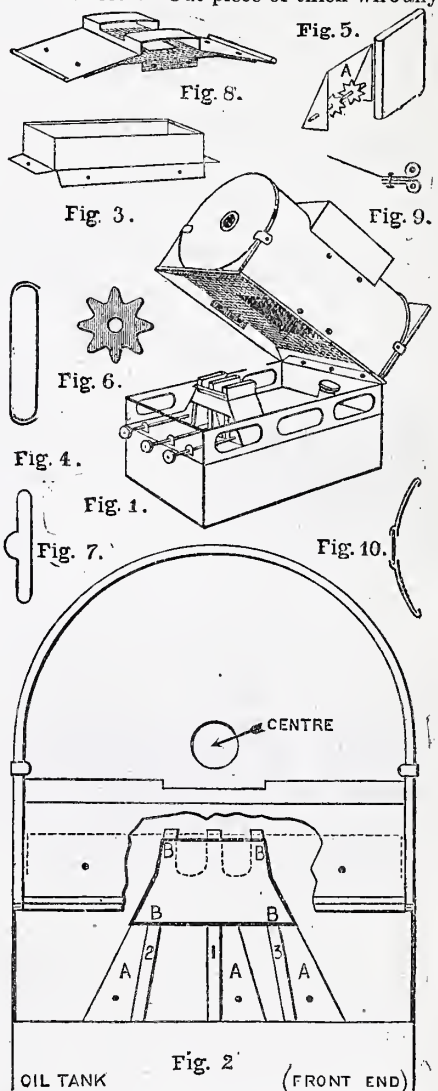

Fig. 2

Fig. 1.—Lamp complete. Fig. 2.—Front View of Lamp (half size). Fig. 3.—Support for Chimney. Fig. 4.—Section of Wick Tube. Fig. 5.—Wick Tube complete, separated to show Arrangement of Parts. Fig. 6.—Wheel for Winder (full size). Fig. 7.—Shape of Hole in Top of Tank for Wick Tube. Fig. 8.—Wick Cover to fit in Dome. Fig. 9.—Section of Hinge. Fig. 10.—Section of Reflector in Frame.

convenient length, and thread it through A (Fig. 5) and two little wheels. Solder wheels in place, and the whole thing on to the wick tube, after trying it. Oil tank $6\frac{1}{2}$ in. by $4\frac{1}{4}$ in., and high enough to bring "centre" (Fig. 2) to level of centre of condenser, usually made by cutting square pieces out of corners of oblong piece of tin, bending up sides, soldering corners, and finally the bottom in. A brass screw bottle top is put in front to fill the lamp—1 in. at least. The holes for wick tubes are to be made the shape of Fig. 7, and the wick tubes soldered in on the under side, at proper

angle, etc. ; nearest side 2 in. from back of tank. A (Fig. 5) is then soldered on to the tube, it having been left long to allow of trimming the bottom to the proper angle. Solder the tubes in the order indicated in Fig. 2, finishing each one before going to the next. Solder strip of tin (B B B B, Fig. 2) across the ends of wick tubes, and a U-shaped pieee of perforated tin (zine might melt) between the tubes, as shown by dots in Fig. 2. Make Fig. 8 of iron, to fit in dome ; length of hole in it, $1\frac{7}{8}$ in. The two ends are turned round the wire which goes round bottom of dome. When properly fixed, the ends of wicks should come exactly in eentre of the hole in it. Rivet a piece of perforated tin to Fig. 8, as shown in that figure and in Fig. 2 by the dots, previously making a hole to freely clear the wicks ; bend down a part of the sides of the perforated tin, and rivet to the sides of the dome as shown. Hinge the dome on as shown in Fig. 1, and in seetion in Fig. 9, and solder the strips of tin supporting dome to the reservoir. Make milled edge winders of the $\frac{1}{8}$ in. brass, notching the edge with a file, and drill and solder on to the winding wires, previously having soldered in place little pieces of metal, as shown (Fig. 1), for rigidity. Get square of thin glass, $4\frac{1}{2}$ in. by $4\frac{1}{2}$ in., to close up front of lamp ; lay it on pieee of iron or copper (latter easiest), turn up edges over glass on three sides, and cut circle out of the centre, $3\frac{1}{4}$ in. (or as much of the circle as you can) ; centre of circle cut out when all is in position, to coincide with centre of reflector. Rivet little elips each side of dome to hold the glass and frame in position. The reflector is an awkward job. Make a frame for it like the one for the front glass, but with the following variations :—It is to be a square with a semi-circular top (there's a bull !), and the middle is not to be cut out, but hammered concave to fit the reflector. Cut $\frac{1}{2}$ in. hole in centre of reflector and frame, and bulge $\frac{1}{8}$ in. of the metal round the hole in the latter outwards enough to lay a small circle of violet or red glass in (see Fig. 10). Put reflector into place, and close in by bending the metal frame over the edge of the reflector round the top and straight down the sides and across the bottom. A piece of the bottom of reflector may have to be eut away. Fasten to back of dome by clips, as shown ; or it can be hinged on to the same wire as the back end of Fig. 8, a part of the latter being cut off the wire to admit of the hinging. The clips method is the easiest. Make chimney telescopic in two or three draws ; total height when drawn out about 10 in. Smallest draw at the bottom, and to fit tight on Fig. 3. In best work there are no sharp edges, and no rivets except in the top, where the piece is riveted on to keep the light from shining on the eeiling. To prevent it slipping down when in use, make a little bulge near the bottom edge of one draw to fit into a corresponding bulge in the top edge of another draw. There will be sufficient spring in the metal to allow of telescoping the draws if the bulge is not too great.

To wind up briefly I may say : Chimney made ; lamp finished. Further particulars to order. That is to say, if any further particulars are wanted, I hope myself that there may be no asking for more, as such requests will indicate either that I have not carried out my explanation to the fullest possible extent, or that I have not succeeded in making myself intelligible—two horns of a dilemma in which I should be sorry to find myself, and from whieh I would fain escape.

## SHORT LESSONS IN WOOD-WORKING FOR AMATEURS.

BY B. A. BAXTER.

### The Saw.

Saws are a difficulty to the beginner, and no small part of his trouble arises from the apparent ease with which a practised hand can divide the stuff. In the first volume of Work there is an excellent description of saws and the form of their teeth, which all beginners should read.

But the use of the saw cannot be aequired by a knowledge of the form of teeth alone. Let me, then, try to give practical advice. Always mark a line for sawing, and, in cross-cutting, let the line be made on two adjacent surfaces, for there are many who can saw a board at right angles as far as breadth is eoncerned, but if the square is applied to test the edge it will be found that the angle is not that desired. In all probability the first attempt to use a saw results in a quantity of saw-dust, an inereased temperature in the operator, and some roughly divided wood. It seems almost absurd, but it is necessary to advise the proper saw to be chosen at first, and to persevere with it, not taking all the saws in stock one after the other to try which is the best, neither try all sorts of positions for the material or for the operator, for if there is anything in which an unstable or vacillating policy is injurious it is in learning to saw. The operator should, as soon as possible, form a habit (of course, if possible, a correct one) and stick to it.

The choice of saws depends on the work to be done. An amateur may need a "half-rip" saw ; that is the coarsest he will need. If he works in hard wood a "hand saw" will do instead ; a panel saw is indispensable. These saws, which have no backs to stiffen them, form a group which may be said to be generally used on the stools, while the tenon and dovetail saws, which are furnished with a back, are for smaller work, and are used on the bench.

The advice given to square the lines on two adjacent surfaces will be more effective on wood of considerable thickness, say upon one of the pieces of $4\frac{1}{2}$ in. by 3 in. advised for a planing lesson. Let the sawyer stand so that he can see the lines appear as one line, or, in other words, let him stand so that his eye is in the same plane as the lines ruled for the guidance of the saw. In such a position he can, with slight alteration of position, glance at either side of the blade of saw, and can exercise watchfulness to check the slightest tendency to depart from the line. If this care is not exercised quite at the beginning of the cut, it will soon be too late to return to the line at all, and the temptation to try again from the other end of the stuff will become almost irresistible. If possible, however, try to avoid this, and master the use of the saw by means of perseverance and careful practice.

One of the most important items to remember is the position of the elbow. Without wishing to dogmatise, seeing that an expert ean do good work in almost any position and with his elbow moving in almost any direction, a beginner ought to make his elbow move in the plane in whieh the saw moves. Just try an experiment : mark a line on a board, then, with a strip of wood held in the hand, try to move the strip so that it constantly agrees with the line, with various positions of the elbow, close to the side and more extended from it, and then apply the result to the use of the saw.

## A FOUR-DRAW TELESCOPE.

BY O. B.

A correspondent, who has adopted the *nom-de-plume* of "Yarmouth," having asked for particulars with reference to the constructing of a small telescope, I purpose in the following paper giving such details as shall enable anyone who has a fair acquaintance with the use of a few tools to eonstruct such an instrument. But here I would say that it is an instrument which requires some skill to make—if finished as it ought to be—and a lathe is indispensable ; yet anyone who can use a lathe and chase a screw will find no difficulty.

The eonditions specified were as follows : A telescope with 1 in. O.G., and to extend to about 16 in. when drawn out. Whilst for the present I shall work to these dimensions, my instructions will be such that they may be adapted to any size of O.G. or length of focus.

*Tubes.*—It will be understood that brass tubing may be procured either stout or light. For a telescope of large dimensions—such as for astronomical purposes—a stout tube is required, but for a light hand instrument, the less weight the better. The tubing we require is known as mandrel drawn ; it is thin, hard, and smooth on the inside, and may be had in all sizes for about 2s. 6d. per pound from any instrument maker, such as Lancaster, Birmingham ; or metal merchants, as Stanton, in Shoe Lane, Fleet Street, London. I have found no difficulty in getting what I wanted from the latter plaee.

It is possible that small dents or pits from blows may be in the tubing. These must be removed, as, to say the least, they would appear very unsightly in the finished instrument. To remove them, lay the tube with the dents on a piece of hard level wood, and, either with a burnisher or a round piece of hard wood, rub the inside of the tube over the indentations, which will quickly bring up the surface level.

*Quantities.*—The sizes and lengths of tubes needed are as follows : body, $5\frac{1}{4}$ in. by $1\frac{1}{4}$ in. diameter ; first draw, $4\frac{1}{4}$ in. by $\frac{1}{20}$ in. diameter ; second draw, $4\frac{3}{4}$ in. by $\frac{17}{20}$ in. diameter ; tube to carry eye-piece, 5 in. by $\frac{3}{4}$ in. diameter ; for the eye-piece, 2 in. of a size to slip into the last-mentioned tube, and 2 in. of a size smaller still for the erector.

In addition to these, we shall require tubing for collars, which may be made out of the same tubing as the next size larger, thus : the collar B may be made of the same size tube as the body A, and so for the other two collars. In addition to the tubes, we shall require a piece of sheet brass $\frac{1}{8}$ in. thick and about 6 in. square, out of which we shall have to cut rings for the ends of tubes and eollars. This, in the main, will eomprise all the brass required.

Chuck a piece of hard wood in the lathe, and turn it down as a mandrel 4 in. long to receive the tube A. True off the ends of the tube at $5\frac{1}{4}$ in. long, and chase an internal thread at each end. The mandrel may now be turned down to receive the tube B, which must be cut off $4\frac{3}{4}$ in. An internal thread must be chased on one end, as shown. Tube C must be treated in the same way.

At one end of D a ring must be soldered on, as at *a* ; this ean be cut off a thiek tube—not mandrel tube. Supposing it is not convenient to get a piece the exact size, then one a little too large can be made to fit by cutting a small portion out of it. Place it on the tube, and bring the edges to meet, and bind it in its place with a pieee

of wire. Run soldering fluid between the tube and ring, and then with a hot bit cause solder to flow into the joint until the ring and the tube are solid. Chuck the tube as the others, and cut it off to 5 in.; on the collar chase a thread, as shown at *a*, and also chase an inside thread on the other end.

*Collars.*—We now require three collars, as B, C, D. Fig. 5 shows one in detail, and to describe one is to describe each. Procure or make a tube, $1\frac{1}{2}$ in. long, to fit tightly the draw on which it is to work. If a piece the exact size is not to hand, then, as before described, take a tube slightly larger, and cut a piece out and solder the joint. On one end sweat a ring of thick tubing $\frac{1}{2}$ in. wide, as at *b*. Chuck it in the lathe, and cut off the end of the ring down to the collar, leaving the collar to project $\frac{1}{8}$ in. Out of sheet brass cut a ring to fit the end of the collar, and wide enough to project $\frac{1}{8}$ in. beyond *b*. This must be now soldered in its place. If due care has been taken, it will be perfectly solid. Replace the whole in the lathe, and turn down the collar as thin as possible consistent with strength. Chase a thread on *b* so as to screw into A, turn down C, and mill the edge. This milled edge must project beyond the tube A about $\frac{1}{16}$ in. The other two collars must be made in the same way—C must screw into B, and D into C. At *a* on B and C, a ring must be soldered as shown, so as to prevent the tubes being separated when drawn out. In each collar four slits are made, as shown (*d*, *d*, in Fig. 5). These are made in a slightly diagonal manner at the diameter of the collar. A slight tap must be given to these two free strips, causing them to spring slightly inwards, so as to press more fully on the tube which slides in them. Thus all shake will be avoided. We can now screw our tubes together, and if our work has been properly done, we shall have a tube perfectly rigid.

*Cell for O.G.*—This cell may be cast or built up. The latter plan I have adopted myself, and have not found it difficult. It is taken for granted that we have procured our O.G. of 1 in. diameter and 10 in. focus. A ring must be made out of stout tubing of 1 in. internal diameter. Chuck it on the lathe, and turn down the ends true. Cut a ring out of sheet brass, the inside diameter, say, $\frac{1}{32}$ in. smaller than the O.G., and the outer diameter $\frac{1}{4}$ in. larger than the tube A. This needs only to be done approximately at first. When soldered together, place it in the lathe and turn it up to the size mentioned, chamfering off the outside of the inner diameter as shown, and milling the outer edge. A thread must be chased on it, so as to screw it into the tube A; and on the inside a thread must be chased to receive the collar to retain the O.G. in position (as *b*, Fig. 1). Care must be taken that the inside of the cell is turned true, so that the O.G. beds perfectly. The stop collar, *b*, may be turned out of the solid, or may be built up like the cell into which it screws. The edge must be milled. The cell, when made, should hold the lens without any shake, and yet without pinching it, so as not to set up a strain.

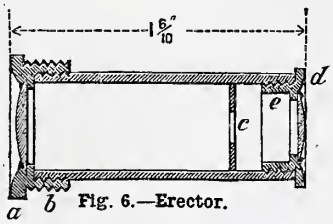

Fig. 6.—Erector.

*Eye-piece.*—For this we shall require a field lens $\frac{6}{10}$ in. diameter and, say, 2 in. focus; eye-lens $\frac{4}{10}$ in., and the focal length one-third that of the field lens. Add the combined focal lengths together, and divide by 2; this will be the distance which must separate them. They must be plano-convex, with their plano sides towards the eye. The better plan for a novice to adopt is, when purchasing them from such an optician as, say, Lancaster, to say what they are for, and ask the distance they are to be separated.

Procure a piece of tubing that will fit nicely into the tube D; cut off, say, $\frac{3}{8}$ in.; turn out one end to the extent of $\frac{1}{16}$ in., so that the field lens will bed on it. The other end must be turned down, and a thread chased on it, as shown. Now place this cell in a chuck, with the end to receive the lens at the right. Place the lens in its position, keeping it steady with a finger of the left hand, and with a burnisher press the bezel over the lens, which will hold it securely. For the cell of the eye-piece turn away the metal on the outside to form a bed for the lens, as shown, and then pierce the centre, leaving a narrow flange. Now cut away the metal at an angle, as in Fig. 7, leaving a bezel around the hole which has to be turned over on the lens, as in the other case. A thread has to be chased on the cell, as shown. A tube must now be cut, of such a length that when the two cells are screwed in their places the lenses shall be separated the required distance. A stop must be placed, as at *b*, to cut off marginal rays. If we were constructing an astronomical telescope, our work would be practically complete; but the youngest tyro in optics will know that the instrument, as it now stands, will invert the objects seen, and thus, for all terrestrial observation, is practically useless.

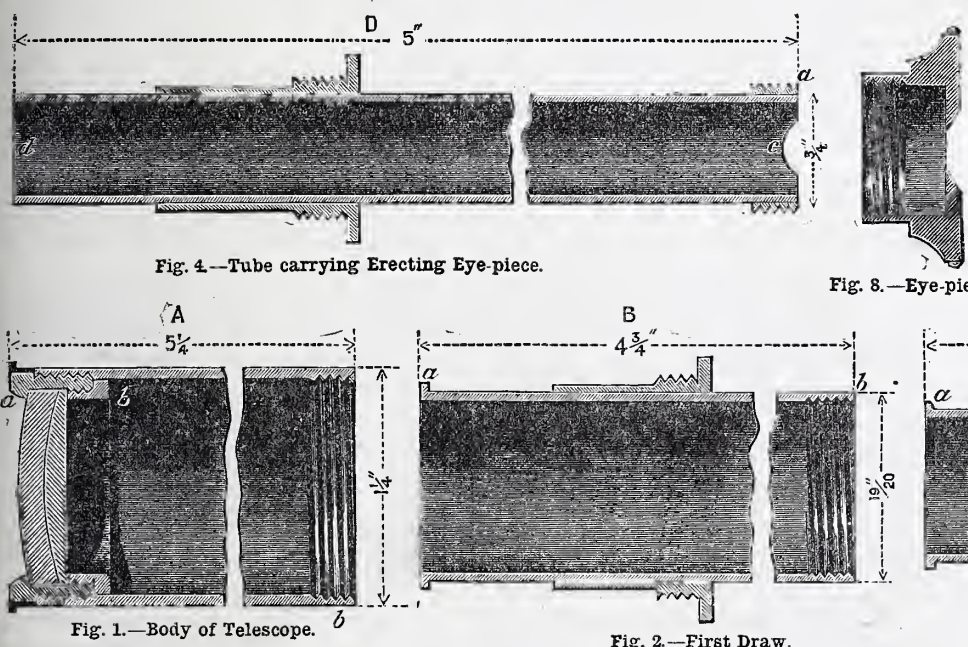

Fig. 4.—Tube carrying Erecting Eye-piece.

Fig. 1.—Body of Telescope.

Fig. 2.—First Draw.

Fig. 3.—Second Draw.

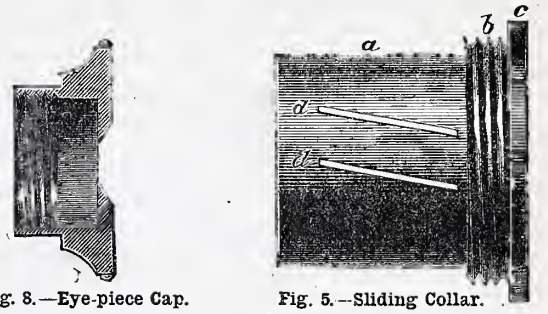

Fig. 8.—Eye-piece Cap.

Fig. 5.—Sliding Collar.

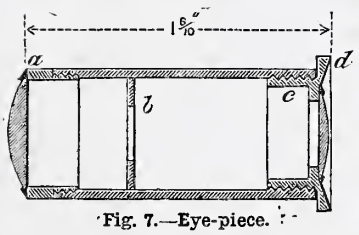

Fig. 7.—Eye-piece.

*Erector.*—For this we shall require two lenses. The one nearest the O.G. may be either plano-convex or double-convex; but if the latter, the greatest convexity must be nearest the O.G. This should be $\frac{1}{2}$ in. diameter and $1\frac{1}{4}$ in. focus. The other is a plano-convex, with the plano side nearest the eye; this may be $\frac{3}{8}$ in. diameter and $1\frac{1}{2}$ in. focus. They must be separated one-half of their combined focus.

After what has been said on cell-making, the diagram (Fig. 7) will be sufficient to show how they are mounted. A stop with a small hole must be placed as shown. The milled edge at *a* must project a little beyond the diameter of the tube D, so that the collar shall prevent the tube from being pulled out.

We now need to make the eye-cap (as Fig. 8); this needs no further description.

A thumb-piece must be taken out of tube D, as shown at *c*, to afford facility to remove

the eye-piece when needed, seeing the flange, *d*, of the eye-piece is flush with the tube.

*Sunshade.*—It is usual to have a sunshade to draw over the O.G., with a cap to prevent damage. If this be desired, then a ring, say, 1 in. wide, must be soldered to body tube at *b*; then a collar must be made to slide over the tube, and the sunshade screwed to this, and a cap or cover fitted to the end. These arrangements will be so simple, that anyone who can master the foregoing details will find no difficulty in working them out. When all is so far finished, the inside of all tubes must be made a dead black, and all the exposed parts of the tubes burnished and lacquered.

## WIRE-WORK IN ALL ITS BRANCHES.

BY JAMES SCOTT.

FIRE-GUARDS—BODGING—THE BODGE—THE BODGING-RING—STAY-BARS—EYE-WIRES—HOOKS.

I HAVE no hesitation in saying that the manufacture of a fire-guard such as I show in Fig. 119 must be numbered among the most difficult tasks a wire-worker is called upon at different times to perform. My earnest advice to my amateur friends is that they should leave fire-guards alone until they thoroughly understand details in other directions, and have become comparatively efficient in handling wire in a practical manner.

I have tendered this counsel because I am aware that a fire-guard is an extremely useful adjunct to a household, and that the fact might induce some of our amateur friends to try their hands at such articles before they had thoroughly grasped the instructions previously given. However, if any are determined to endeavour to accomplish making one, they will find these notes accurate and "plain sailing;" for I have dotted them down roughly while observing the process through which a fire-guard passes, and have, just before penning these lines, experimented personally.

These articles are not separately made and finished complete, nor, indeed, are many things so made, but a quantity are put through one stage previously to passing through another. However, it will serve no useful purpose for me to name the different processes. I will begin and end with a single guard.

They are made in various sizes, and are usually proportioned to the height; but I shall not give *all* the dimensions, as there are so many, and I do not see the need of my doing so. Should any reader, however, desire fuller particulars, I shall be pleased to give them to him, although I have endeavoured to obviate the necessity of any such action on his part in the course of my following remarks.

Supposing a certain height is agreed upon, the first proceeding will be to bend a wire as in Fig. 127, the top being half-circular. There will be a bottom wire (indicated as A B in Figs. 119, 122, and 123), which will finally be nearly half-circular in shape, but will be used in the straight until a point is reached of which I shall say more later on.

A little extra should be allowed upon this for the purpose of twisting the corners where the wire, A B, comes in contact with the upright arch.

A piece of work should now be laid out on the bench, of a mesh previously decided upon, the width of it exceeding by a trifle the length of the bottom wire, A B. The upright arch should now be placed upon the work, one corner of the former touching one end of the bottom wire, A B (Fig. 126), and the length marked off, giving a very considerable excess over the length of the upright arch, for the reason that sufficient must remain to be bent dome-shaped, as in Fig. 119.

When the piece of work is cut out, should it be found correct in size to fit on to the frame (which I have designated upright arch and bottom wire, A B, for convenience' sake), if more than one guard of these dimensions is required, it will be preferable to cut all the necessary pieces of work ready according to the first piece.

When this stage is reached, the work is ready to be turned over on to the bottom wire, A B (before that wire is bent arc-shaped, bear in mind), and will then be as in Fig. 122. Parallel to the bottom wire, A B, at a certain distance from it (which distance will depend upon the height of the guard), will be another wire (C D), temporarily secured in position by being tied at odd intervals. Between these two stay-bars will be a pair of eye-wires (Fig. 125), one towards each side of the work, in order that the movable hooks (Fig. 132) may be fastened to them in such a manner that sufficient space is afforded for them (the hooks) to work freely and be attached to the bars of a grate to hold the guard in proper position. The wire, C D, will then be laced to the work.

What requires to be done when the work is thus far ready is to bend the bottom wire, A B, and the wire, C D, to their requisite arc shape, which is done by means of the bodging-ring shown in Fig. 120 (of which more anon). The appearance of the job will now be as a piece of netting bent, being really an arch whose both openings are the same size as each other.

When this point is attained, the upright arch wire should fit properly in between the wires along the part which forms the bottom edges of the arch of bent work. The latter wires must be temporarily tied to the arch wire, preparatory to being turned over it. It will be found that the wires can only be turned over on to the arch wire along the straight sides of it, thus leaving loose ends all round what will afterwards be the arc-shaped portion.

The all-important work of bodging takes place at this period, but before describing it I must return for a short time to the eye-wires. As before said, one is shown in Fig. 125. A straight wire has its ends bent as shown, either by means of fingers, pliers, or something as convenient, and is then again bent, at a short distance from each end, round pegs, the holes or eyes being thus formed (Fig. 124). When fixed in position, by placing one end over the bottom wire, A B, and the other end over the bar, C D, they are there squeezed down as tightly as possible by the aid of the nippers. Of course, these eye-wires will be upon the inside of the job, as also will be the wires, A B and C D.

Now for the bodging—by the way, a peculiar but appropriate term. First, there must be a bodge. This is shown in Fig. 121, and will be turned from hard wood. An idea of its most suitable proportions can be gleaned when I say that the narrowest part shown in my sketch is intended to serve as a handle. The next accessory will be a metal hoop about four or five inches deep, and about the same diameter as the width of the guards. The work is placed upon it in such a manner that that end which is to be dome-shaped partly covers the orifice of the bodging-ring. A few gentle taps are given with the bodge, the work meanwhile being shifted regularly with the left hand, but never having any other part over the bodging-ring than that which is to be dome-shaped. The consequence of these actions is a depression of the wires so tapped or bodged, and if these operations are continued systematically, a dome top will be the result. Many more words concerning the bodging will be superfluous, for I am certain that neither myself or anyone else could possibly describe the details clearer if confined, as I am naturally compelled to be, to pen and pencil. To give more diagrams would be useless, as wire is such open work to represent that an idea of it cannot always be conveyed in drawings, and my only fear is that those I do give, although drawn correctly, may not be instantly intelligible in every case. The wires will then be turned over the half-circular portion of the upright arch.

Another difficult part in connection with fire-guards is the accomplishment of a pair of hooks for purposes previously mentioned. To me the task of describing the routine through which a piece of wire passes before it can be called by the name under consideration, is indeed a difficult performance; but to show that I have at heart most earnest wishes that the knowledge which I have gleaned from my practical friend should be imparted to all who feel desirous of becoming properly acquainted with it, I have decided upon a scheme by which I consider I shall benefit my readers and also satisfy myself, of which I must postpone explanations until I have completed a few more descriptive paragraphs.

These hooks are bent by means of pegs driven into the bench at stated distances apart, the distances depending upon the size of the hooks required. There will be six pegs, placed in relative positions shown by Fig. 128. In that diagram the whole lot are shown complete, and I have lettered them—the letters in the companion diagrams illustrating a correspondence of parts.

First, a straight wire has a hook formed at one end, which is held to the left in beginning the after-bending. This end hook is fixed on the extreme left-hand peg, A, and the wire is bent round the extreme right-hand peg, F (Fig. 128). In this state it is taken off the bench. In the next bending it will not lay flat, as it unavoidably appears to do in the sketch (Fig. 129), but one bent half will be exactly above the other, as I have endeavoured to explain in Fig. 133. In that diagram it is intended that only what is the lower half in the drawing shall touch the bench. This being understood, then, I will proceed.

The wire is, in this position, placed by the sides of pegs D and F, in such a manner that the bend, G, does not project beyond the peg D, and is then bent round as in Fig. 129. Then at point G each half is squeezed close together. It is again taken from the pegs and replaced against them, as in Fig. 131, the longer portion being exactly above the shorter, and the *longer portion only* bent as in that diagram. In the next bending, the hook (so far finished) must be turned upside down and fixed in contact with the pegs, as in Fig. 130, and the longer portion again bent round peg F. The hook will be finished when the remaining straight end is formed into a bend similar to that at the other end, and will then present an appearance similar to that represented in Fig. 132.

An examination of the arrangement of the pegs will show that any number of hooks may be made of all exactly the same size as

each other. The pegs form a gauge for them. When the first piece of wire is formed into a hook, it will naturally be desirable to know what its length is if any more than a few pairs are required. To arrive at this conclusion, it would seem that it would be necessary to straighten out the hook again in order to measure it; but if my following hints are accepted, no such toilsome course need be resorted to.

Have a length of wire a few inches in excess of what it may be roughly estimated will be required. Measure it, and then make the hook. It will be seen that by subtracting the length of the surplus piece from the whole, the remainder will give the proper length occupied by the hook. I believe this explanation is clear enough, and my readers who properly understand must not think I am doubting their intelligence by an example—which I give for the benefit of those of my younger readers who may not quite understand what I mean by what I have said above. Supposing the original piece of wire is ten inches long, when the hook is formed there will remain a portion at the end which will have to be cut off. If this latter measures two inches, then the remainder, eight inches, will be the length of the piece of wire necessary to form the hook.

Each hook will be secured to the guard by having its ends passed through the holes in the eye-wires and squeezed down so that it may swing to and fro. The corners, where the upright arch wire comes in contact with the bottom wire, A B, should be slightly twisted. A handle will be required. This is simply a piece of bent wire squeezed down upon the dome part of the guard.

Sometimes these articles are mounted with brass. This is done by having a brass tube, which is slit its whole length along one side, and then bent round to the shape of the guard, and, finally, hammered down over the frame of the guard. Another tube will be necessary for the bottom.

Now I will speak further of what I proposed doing, so that myself and my readers might be satisfied. Should any of the latter not quite grasp the purport of my previous remarks, I will be pleased to supply him with a card upon which I would draw in plan the exact relative positions, full size, of hooks of any dimensions he desires. He must tell me the length and width he wishes it to be *when finished*. The one thing that I stipulate for on his part is, that, when writing to me, he shall enclose sufficient of the requisites to cover postage, of which any balance remaining would be returned. I shall be glad to assist my readers in this way in any direction in which they may require enlightenment.

I have said that articles with brass or other mountings would be dealt with in future papers; but such an enormous number of fire-guards are made quite plain, that I consider their description rightly belongs to this section, and I have included them in this section accordingly.

## MEANS, MODES, AND METHODS.

### Black Stain.

A splendid black stain for wood-work can be made and used in the following way:—Take out the burner of a gas-jet and suspend a piece of iron or tin above it, and allow it to smoke on the tin; in a few minutes a fine black powder will accumulate. This should be collected by scraping it off with a knife. If a piece of wadding or flannel, moistened with French polish, be dipped in the black powder, and rubbed on the article to be stained, it will be found to stain (and polish at the same time) a beautiful jet black.—H.H.

### A Cheap and Useful "Graph."

The following directions for making a cheap and useful "graph," or copying materials, are based on a recipe given in the *Papier Zeitung*:—Soak four parts of best clear glue, preferably Scotch, in a mixture of five parts pure water and three parts liquor ammonia until the glue is thoroughly softened. Subject it to gentle heat until the glue is dissolved, and then add three parts of granulated sugar and eight parts of glycerine, stirring well and letting it come to the boiling point. While hot, spread the mixture upon clean white blotting-paper with a broad brush until the blotting-paper is thoroughly soaked and a thin coating remains on the surface. Then put it aside to dry for two or three days, when it will be ready for use. The writing or drawing to be

copied is done with the usual aniline ink upon writing-paper. Before transferring writing to be reproduced to the blotting-paper, wet the latter with a sponge or brush and clean water, and allow it to stand one or two minutes. Place the written side down, apply gentle pressure to get rid of any air bubbles, and submit the whole to gentle pressure for a few moments. The written paper must then be removed, and impressions taken in the ordinary way. When the impressions begin to grow weak, damp the surface of the "graph" a second time. This "graph" does not require the writing to be washed off; all that is necessary is to put it aside for an entire day, or a day and a half; or, in other words, from twenty-four to thirty-six hours, when the surface will be ready for a new impression.

### A Hard and Fast Cement.

The introduction of the following cement, that is said to stick on anything, is attributed to Professor Alexander Winchell:—Take of clear gum arabic, 2 oz., of fine starch, 1½ oz., and of white sugar, ½ oz. Reduce the gum arabic to powder, and dissolve it in as much water as the laundress would use to render 1½ oz. of starch fit for use. Dissolve the starch and sugar in the gum solution. Then place the mixture in a vessel and plunge the vessel itself in boiling water, and let it remain there until the starch becomes clear. The cement should be as thick as tar, and remain so. It can be kept from spoiling by dropping in a lump of camphor, or a little oil of cloves or sassafras. This cement is said to be very strong indeed, and will cause glazed surfaces to adhere perfectly. It is useful for repairing specimens of rocks, minerals, or fossils that may have been accidentally broken.

### How to Imitate Old Bronze.

An excellent method of imitating antique bronze has been lately introduced in some of the art work of that class. It is well known that repeated applications to copper or brass of alternate washes of dilute autic acid, when subsequently exposed to the fumes of ammonia, result in giving to the metal the colour of antique green bronze; but workers have long been on the look-out for a more rapid method of obtaining this appearance. It has been found that the desired result may be obtained by immersing the articles in a solution of one part perchloride of iron to two parts of water, the length of the immersion regulating the depth of the tone. A similar result may also be obtained by boiling the article in a strong solution of nitrate of copper, or by dipping the articles to be coloured in a solution of 2 oz. of nitrate of iron and the same quantity of hyposulphite of soda in a half-pint of water. The article must then be dried and burnished.

### A Wrinkle for Bookbinders.

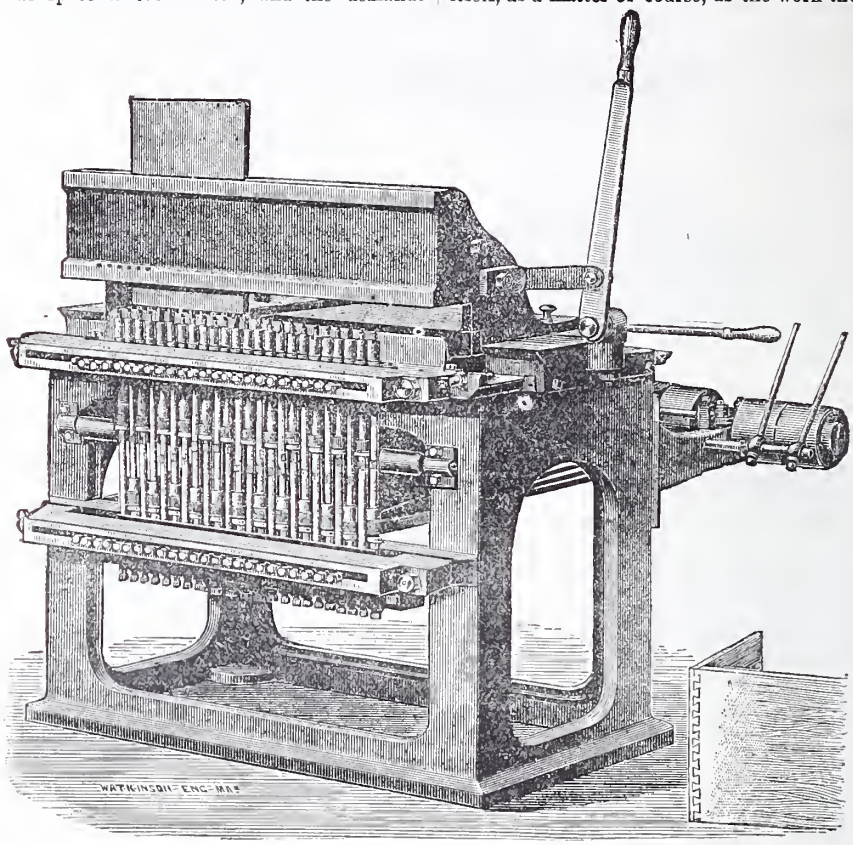
In gilding the edges of books, trouble sometimes presents itself in the gold cracking off and spotting, especially in works of art whose plates have been worked on thick and pulpy paper of a greasy nature. This can be remedied by adopting the following process:—After the edges are well scraped, wash with a solution of about five drops of muriatic acid to 2 oz. of oxalic acid; this will destroy the grease. Then paste, wash, and when dry polish with a round agate burnisher; this will give the edges of the plates a hard surface. Now apply the gold with size in the ordinary way, and the result will be a bright, solid edge.

## OUR GUIDE TO GOOD THINGS.

**** Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

### 90.—Pickles' Improved Dovetailing Machine.

The accompanying engraving is an illustration of a new and improved dovetailing machine recently introduced by Messrs. John Pickles and Son, Saw Mill Engineers and Wood-cutting Machinists. Those who are acquainted with machinery will readily recognise its construction and action from the illustration itself; and as space is too limited, and the demands on it too great, to deal with these points in as complete and satisfactory a manner as I could wish for the instruction of the uninitiated, I will merely take occasion to point out that the machine is of the most modern design, and is specially adapted for dovetailing furniture and all parts of furniture in which dovetailing is desirable, and, indeed, absolutely necessary, as, for example, in all drawers, boxes, etc.; and it is also most useful in packing-cases, and for all kinds of cases in which goods are sent out, whether on a large or small scale, and in which the dovetail joints are for the most part numerous. Messrs. Pickles & Son write to say that they have been led to submit the illustration to the notice of the readers of WORK in consequence of "an admirable paper on dovetail joints" which appeared in page 389 of the current volume, an expression of opinion which is valuable in itself coming from the source from which it does, and which shows that WORK finds its way into the offices of men of experience and sound judgment, who are able to appreciate the information contained in its pages at the proper value. They proceed to say: "We have just made a machine for the largest cabinet factory in London as per illustration enclosed" (that is to say, the illustration that I have been enabled to give here). "This machine will dovetail work up to 30 inches wide, all in one operation, making both pins and tails, and not only that, but rounding the pins off to fit the dovetails. Different pitches of dovetails can be produced on the machine." The rounding off of the pins to fit the dovetails is of the utmost consequence, particularly in all hard woods, as it requires no undue amount of cramping up to get all the pins fairly home. A very important feature in this machine is that the distance between the cutter spindles can be varied so as to produce different pitches of dovetails and pins by having different sizes of cutters. The machine is easily and expeditiously worked, and is made in three sizes—namely, No. 1, to take 30 inches in width; No. 2, 24 inches; and No. 3, 18 inches. It is well worthy the attention of all who are engaged in the furniture trades and packing-case making of every description. To amateur wood-workers it will not commend itself, as a matter of course, as the work they do in dovetailing is by no means so extensive as to induce them to proceed beyond careful work with the tenon or dovetail saw, or such simple machinery as may be devised for home use, in which there is but one cutter, and the work is made to travel laterally until the work of dovetailing is completed. I do not say that such a machine exists and is purchasable, but that by the exercise of a little thought and ingenuity such a machine may be contrived, even as machines for mortising and tenoning have been made for home use, and have proved of considerable assistance to the maker and contriver.



Pickles' Improved Dovetailing Machine.

### 91.—Serial Publications and New Editions.

I have received the current numbers of "The Machinery Mart" for August, September, October, and November; "The Amateur," published by Messrs. Henry Zilles & Co., for September, October, and November; and the fourth and enlarged edition of "Photography in a Nutshell," by the "Kernel." As the merits of these have already been noticed in "Our Guide to Good Things," it is unnecessary to do more on the present occasion than to acknowledge their receipt.

THE EDITOR.

# SHOP:

## A Corner for Those who Want to Talk It.

*** *In consequence of the great pressure upon the "Shop" columns of* Work, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—Letters from Correspondents.

**Testing Accuracy of Framework.**—G. P. (*Elgin*) writes:—"I notice that no figures are attached to the second of the two diagrams which accompanied my communication on 'Testing the Accuracy of Framework' (see Work, p. 523, Vol. III). In Fig. 2 referred to, the top left-hand corner should be marked 'A,' the top right-hand corner, 'B,' the lower right-hand corner, 'C,' and the lower left-hand corner, 'D.'"

**Hand Saws.**—A. R. (*Scorrier*) writes:—"In No. 137 of Work, p. 523, letters appeared from myself and Chopstick criticising M. Powis Bale's article on 'Saw Teeth' (see p. 421). I would like to call the attention of the readers of Work to the criticism on p. 523 by Chopstick, which any practical saw-sharpener will deem absurd. If Chopstick means what he wrote on p. 523, I can only say that his practical experience in saw-sharpening must be very limited. Chopstick said the form of teeth shown in Fig. 1 is the best for cross-cutting. I understand that Figs. 1, 2, and 3 were represented as rip-saw teeth. Chopstick further said that Fig. 2 was the best for ripping, and Fig. 3 the right shape for cross-cutting logs. If the readers of Work will refer to the article on p. 421 by M. Powis Bale, they will notice that the rake of teeth (Figs. 2 and 3) is much the same, and the angle is about 50°. Now, I ask, what man can work a hand saw with teeth at such an angle? Again, it is well known that the rake of teeth for cross-cutting should not be as much as for ripping. The teeth in Figs. 2 and 3 have too much rake even for ripping, and Chopstick will actually say that Fig. 3 is suitable for cross-cutting logs! Chopstick will please allow me to tell him that for cross-cuttiug logs there should be but very little (in some cases, not any) rake in the teeth. It would be impossible for two of the strongest men I know (and I have had to do with some strong men, especially above the shoulders) to work a two-handle cross-cut saw in cutting logs with rake in teeth as in Fig. 3 (p. 421). Again, in reference to everyone sharpening a saw to cut any kind of wood: I know many men who have tried to sharpen saws, but the saws have been made a deal worse by the so-called sharpening. I would not advise anyone to practise sharpening a good saw, but to follow some of the instructions in Work, practising for some time on an old saw or pieces of saws. In reference to a needle running down the saw teeth, Chopstick may sharpen a saw that a needle may run the whole length of teeth before it falls off, and another saw may be sharpened even better, and the needle will fall off before it runs half-way down the teeth. In fact, a saw may be improperly sharpened and a needle run the whole length; while in another saw, that is properly sharpened, it would not do so. If Chopstick can give no better proof than that of the needle, allow me to tell him, as a practical man, there is more than that required to convince me that his saw is properly sharpened. I might add that from five to seven teeth in a hand saw will be the most suitable for cross-cutting, and for ripping, four teeth or points to the inch will be far better than three points to the inch, and if teeth are properly sharpened, 3 in. deal can be easily ripped with it."

**Splicing a Mast.**—L. L. H. (*Falmouth*). — My reply to Nauticus (see No. 137, p. 523) was not quite explicit enough; I will therefore supplement it. Into the two nicks in the mast to be cut (shown at A and B in the drawing) nail two narrow strips of wood, or battens, perpendicularly—*i.e.*, at right angles to the mast. They must be sufficiently long to stand *well* above the spar as it lies on the ground. If a straight-edge is laid on the mast against these strips and moved up and down like a see-saw, always touching the strips, it will be found to be very easy to scribe a straight line on the mast, which, when sawn upon, will make a true mitre of the end of the spar. This is the method invariably used by mast-makers. A mitre-box as suggested by the Editor would not be practicable for the very large and heavy spars with which a mast-maker has to deal."

**Sheet Metal Work.** — Erratum. — Tinker writes:—"In my letter which appears in page 523, No. 137 of Work, there is a slight misprint. Instead of half a middle plate being 15 in. by 15½ in., it should read 15 in. by 5½ in."

**"Work" Certificate Frame.**—W. W. (*Elswick*) writes:—"I forward this to you as a design for Certificate frame. It gives your readers an idea as to how I intend to frame my certificate, as I am proud to think that I was a successful exhibitor in your late Exhibition. This frame is intended to be turned in the lathe out of two pieces of mahogany, which will be suitable to the dimensions given in the design. The long columns are turned with a ball at each joint, and a ⅜ in. bole put through each ball, with the ends finished as shown. Then they

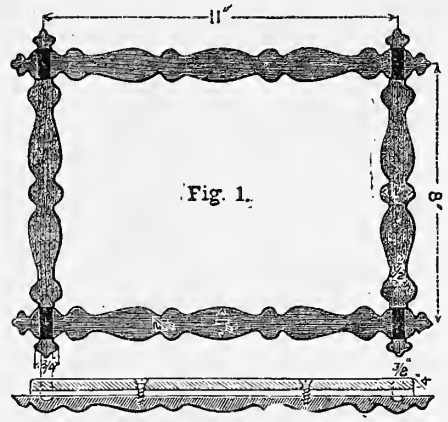


Fig. 2.

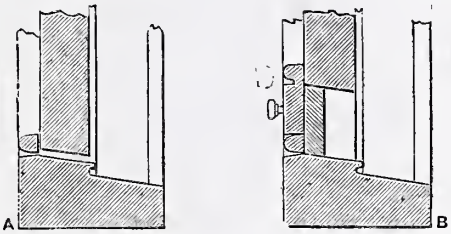
"Work" Exhibition Certificate Frame.

are carefully sawn through the centre, and form the two sides of the frame. The short columns are turned with joints made to fit the hole in ball, and ends turned as shown. These sawn through centre as in long columns form top and bottom of frame. Fig. 2 is a section showing edge, and how to fasten backboard to frame."

**Draught Excluder for Doors.**—The Rev. H. H. (*Burton-on-Trent*) writes:—"I found the following simple plan very effective last winter for excluding draught from the bottom of a door: Roll up a sheet of brown paper the length of the door; the roll should not be solid, but hollow, to make it springy. Fasten a piece of elastic to a button, and pass the end of the elastic through the end of the hollow, and then through the thickness of the paper: the button will form a stop; then pass the end of the elastic under the door and neatly tack it to the other side. Treat the other end of the roll in the same manner. The elastic and springy roll work comfortably together over edges of carpets and other inequalities, and always clip the door and floor with an easy but sufficient pressure. The roll can be placed either inside or outside the door, and can be covered with carpet, oilcloth, etc., according to the requirements of taste. Another simple and effective plan is to fasten elastic to the under ends of the door-mat and floor or jamb of such a length as to keep the edge of the mat always gently pressed against the door. Draughts to the feet are not only a nuisance, but dangerous."

**A Ventilator for Windows.**—T. S. (*No Address*) writes:—"It is sometimes rather too cool to have the windows open, and not cold enough for a fire to be necessary, and our rooms are stuffy and unpleasant, so here is a mode of ventilating that perhaps may be useful to some of the readers of Work. Procure two pieces of wood, 2 in. wide by ¾ in. thick (the one before me now is of yellow deal, varnished); the length of one of the pieces is about ½ in. less than the distance between the pulley stiles of the window, or the length of the bottom rail of the sash; the other piece should be cut to fit loosely in between the beads of the sash-frame, or about 1½ in. less than the first piece, and should be beaded



Ventilator for Windows.—A, Section of Window without Ventilator; B, Section of Window with Ventilator.

or chamfered on one edge. Now put the first piece on edge on the sill of window, and shut the sash down on it, and put the second piece against the sash, to hide the first piece. If the two could be screwed, nailed, or otherwise fixed together as they are so placed, the ventilator is complete. Of course, as one side shows in the room, screws and nails should be put in from the outside, so you had better mark where they should be fixed together, and take them out and complete. The advantage of this construction is that there is in no place a straight joint. There is a rebate all round top, bottom, and both ends. No bolts or other fastenings are required. A small knob is perhaps useful to hold it in position while shutting the sash, or without the knob you may pinch your fingers."

**Lamp Explosions.**—W. G. (*Sherborne*) writes:—"After what we have heard about the death by burning of Lord Romilly and the fearful lamp accidents at Liverpool and in Wiltshire, people would do well to use the Maguay electric lamps, which cannot explode even in a coal mine. They are made complete with batteries for hanging on a wall, or the battery can be placed under the dinner-table and light a table lamp; they can also be used to drive motors. A few days ago a single firm is known to have ordered £260 worth of these electric bicycle lamps, which cannot be blown out in the storms."

### II.—Questions Answered by Editor and Staff.

**Cocoa Fibre.** — Don. — I cannot give full particulars to describe the process of preparing fibre for weaving into mats; and, if I could, Don would have to see it done, and ask numerous questions on the subject to be enabled to do it himself. I recommend him to get an order to view some prison where this sort of labour is carried on, when, no doubt, he could pick up many "wrinkles."—J. W. H.

**Burnishing Machine.**—W. A. H. (*Haworth*).—A machine for this purpose consists of two iron cylinders, the upper one polished, geared together with tooth-wheels working in headstocks, just like one of the ordinary clothes-wringing machines, which you may take as a model, with a top bar, strong coach-spring, and screw to put on the pressure, as in the wringer. Now plane a piece of iron about ¼ in. thick, the width of your rollers and rather longer, polishing the upper surface; and on your side frames cast a rib on which the end may slide, exactly on a level with the top of the lower roller. Have a small atmospheric gas-burner fixed under the plate, so that when it is drawn out to the full extent it may be heated. You may have a stop, to prevent its going too far, if you like. This plate, when between the two rollers, will move when they are turned, like the box of a mangle; but it is, of course, better to fix a rack and pinion of the same pitch as the wheels under the plate or table, and gear a small pinion on the same shaft into the tooth-wheel of the bottom roller; and having outside that a handle keyed upon it to turn the machine with. This table must be oiled when not in use, and all oil and rust polished off with dry whiting when about to be used. Lay your photos, face down, on the table, which should be heated just so that you can bear to lay your hand upon it; and adjust the pressure gradually, putting a little more on as the mount and paper get thinner with the rolling, until the gloss is satisfactory. If you have no gas, a paraffin lamp will answer, if you do not put it too near the table; as, if you do, it will cover the underside of the table with thick layers of lamp-black. If you cannot work to this description, we will, if you write again, give working drawings and dimensions, size and pitch of wheels, rack, pinions, etc.—J. W. H.

**Medical Coil.** — Achlum. — From your rough sketch of the apparatus, I gather that you have made a medical coil of two powers, although in your letter you describe it as an "electric battery." A coil and an electric battery are two separate things. The right way to connect the wires is as here directed if you have two secondary coils: Connect one end of the primary wire to one of the terminals, marked on your sketch "to battery;" connect the other end of the primary wire to one end of the electro-magnet wires; then connect the other magnet wire to the contact screw pillar, and run a wire from the contact to the other terminal, marked on your sketch "to battery." This will complete the primary circuit. Now for the secondary circuit: First, connect the commencing end of the first secondary to one of the studs marked "to handles;" connect the other end of this wire to the stud of the switch marked "No. 1," the other stud of this being connected to the opposite "handle terminal." This will complete the first power. The second coil of wire will start from the same stud as the first, and will finish off at a stud on No. 2 switch, thus forming the second power. All connections made beneath the base.—G. E. B.

**Unanswered Letters.**—E. D. R. (*Camberwell*).—A reply to your first letter was prepared in due course, and was awaiting space for publication in "Shop," when your second letter came to hand. There is great pressure upon "Shop."—G. E. B.

**Battery for Electric Light.** — Ignoramus. —The cheap electric light battery described on page 428, Vol. III. of Work, in reply to F. G. (*Paddington*), will furnish enough current for two 2½ candle-power 8-volt lamps. The charge will run for about six hours, and then will have to be thrown away, the battery plates cleaned, the zincs re-amalgamated, and the cells charged with a fresh solution just before starting the battery again. This must be done every evening, if the light is required for a period of from four to six hours. In any case, the plates should be lifted out of the solution when the battery is not at work. If this is not done, the zincs will waste away. For these reasons the battery is not suitable for electric bells.—G. E. B.

**Electrical Engineering.**—A. T. (*Horwich*).—I do not know of a "Guide to Electric Engineering, Mechanical Engineering, and all other Engineering Trades;" nor do I know of a book containing the Board of Trade examination questions on these subjects. Several good books on electrical engineering and mechanical engineering have been published, among the best being "Electrical Engineering for Electric Light Artisans and Students," by Messrs. Slinger & Brooker, price 10s. 6d. "Questions on Magnetism and Electricity," by F. W. Lavender, price 3s. 6d., and "Exercises in Electrical and Magnetic Measurement," price 3s. 6d., are books which may be useful to you. By writing to the secretary of the City of London Guilds Central Institute, South Kensington, S.W., you may get information respecting the latest examination papers of this Institute. Copies of such papers are sometimes on sale.—G. E. B.

**Battery for Lamp and Coil.**—T. S. (*Caledonian Road*).—The small lamps mentioned by you (under the name of "Aladdin Electric Watch Stand") may be worked with current from a small ebonite accumulator, a small lithanode battery, a chloride of silver cell, or a small battery, with zinc and carbon elements; the cells being charged with bichromate of potash, or chromic acid solution. If you had described your battery, I would have told you how to make a suitable solution. Bichromate or chromic acid solutions are made by dissolving 3 oz. of either salt in 1 pint of warm water, allowing this to cool, and adding a large wineglassful of sulphuric acid in drops at a time. This is the most lasting solution for a small cell with carbon and zinc plates, whether used for small electric lamps or for working street coils; but even this will only last for a six hours' run with lamp or coil. A 25-volt 16-candle power lamp will require a battery of thirteen half-gallon bichromate of potash or chromic acid cells, connected in series, to light it properly; and this battery will have to be cleaned and re-charged after a run of from five to six hours.—G. E. B.

**Gas Engine.**—AMATEUR.—What I should advise you to do is to decide what kind of engine you want to make, and then an advertisement in WORK would bring forward some reader who had a set of drawings. These I should advise you to study thoroughly, making yourself as complete a master as possible of all the details, meanwhile making notes of what you do not grasp; then write again, stating definitely what it is that you do not understand, when, I have no doubt, someone will be able to help you, and that willingly.—P. B. H.

**Indiarubber.**—OLLGARTNY.—The arrangement sent us by our correspondent is not new, having been used by the Fabers some years since, and was, we believe, introduced by them. There is no doubt that it is an improvement on the plan named by our correspondent; but any patent would have to be confined to the exact thing shown, and this modification would most probably have been covered in some prior patent. But this could only be satisfactorily ascertained by a search for and examination of such patents as have been already taken for this object.—C. E.

**Picture-Frame Gilding.**—EUSTACE.—It is impossible to re-gild picture frames without experience, being a trade in itself. If the frames are really English gilt—*i.e.*, not lacquer, or German gilt—they can be cleaned by being delicately sponged with lukewarm water, to remove the dirty size, and, when dry, re-sized. Black-stained frames are best polished, egg-shell finish.—F. B.

**Lantern Lens.**—F. J. K. (*London, W.*) has a set of lenses from wet plate camera, and wants to know if he can use them to an ordinary lantern to show photographs and paintings on glass, which he has been trying his hand on, and says:—"Of course, if I have to add another lens I don't mind;" and, further, that the lenses he has are 1½ in. diameter. It is hardly clear what F. J. K. means, but he must know that in a lantern, in addition to the front lenses, for which, no doubt, his present lens would be available, he will require a pair of condensers, from 3½ in. to 4 in. in diameter, and of about 6 in. focus. These elementary facts must be grasped before a lantern can either be made or used. And then as to the photographs, etc., referred to, it is not clear whether he means ordinary photographs or transparencies made purposely for the lantern. The former can certainly be shown, but not by an ordinary lantern. I should advise F. J. K., in the absence of a more instructive manual on the subject, to get a catalogue from some optician who makes lanterns a speciality—and there are many—where he will find much useful information. At present it seems he does not know the elementary optical conditions required. If he can state his wants more definitely I shall be glad to help him.—O. B.

**Tin Can Ear.**—APPRENTICE.—The ear which you send as a sample is called a canteen ear, and you can obtain them from Messrs. Hopkins & Sons, Granville Works, Birmingham; Perry, Son & Co., Temple Street Works, Wolverhampton; T. Paul Lomax, Moor Street, Birmingham; or any other maker of tinmens' mountings.—R. A.

**Sheet Metal Work.**—I. J. W. (*Farnworth*).—You will find articles on the above as follows: Vol. I., Nos. 17, 23, 32, 42; Vol. II., Nos. 67, 71, 78, 93; Vol. III., Nos. 127, 134. There are several more to follow.—R. A.

**Oval Chuck.**—A. W. D. (*No Address*).—The sketches show an alternative guiding ring which may suit A. W. D.'s lathe, though it is very difficult to prescribe for an unseen patient. The principle of the oval chuck is, of course, rotation, combined with a definite reciprocating motion. Any means which will secure this end may be adopted. If the tool could be made to advance and withdraw twice in a revolution, no complicated chuck would be necessary, though the arrangement would be very difficult to obtain. Yet A. W. D. will see, on consideration, that it would be possible. One great difficulty would be to turn various diameters with travel of tool thus fettered. The alternative to this travel of the tool is the travel of the work, and the oval chuck secures this. A. W. D. is aware of the fact that this oval chuck is suited for work which is *wholly* supported by it, without any help from the

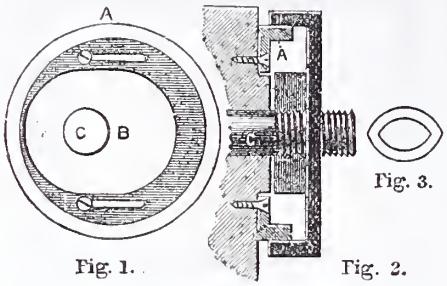


Fig. 1. Fig. 2. Fig. 3.

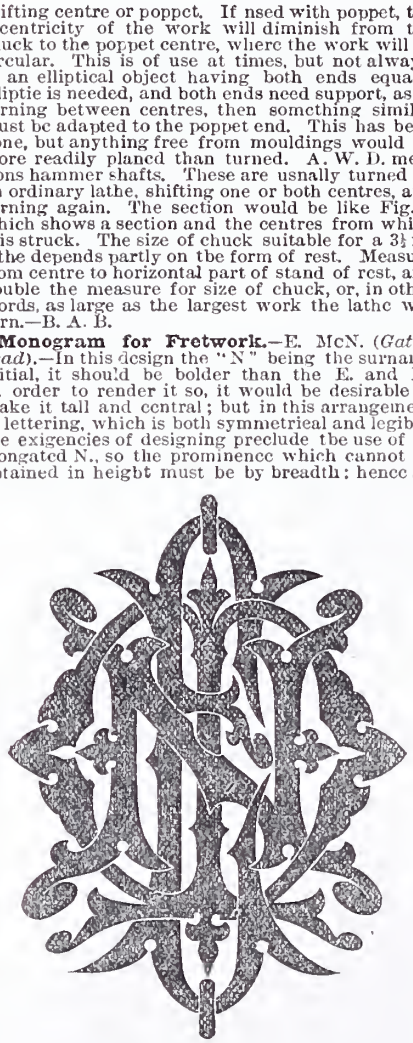
**Suggested Form of Guiding Ring for Oval Chuck. Fig. 1.—Front View—A, Guide Ring; B, Centre, cut away to allow it to be set eccentrically; C, Centre of Mandrel, to be fixed with Screws in the Slots marked. Fig. 2.—Section. Fig. 3.—Section of Hammer Handle, showing Centres.**

shifting centre or poppet. If used with poppet, the eccentricity of the work will diminish from the chuck to the poppet centre, where the work will be circular. This is of use at times, but not always. If an elliptical object having both ends equally elliptic is needed, and both ends need support, as in turning between centres, then something similar must be adapted to the poppet end. This has been done, but anything free from mouldings would be more readily planed than turned. A. W. D. mentions hammer shafts. These are usually turned in an ordinary lathe, shifting one or both centres, and turning again. The section would be like Fig. 3, which shows a section and the centres from which it is struck. The size of chuck suitable for a 3½ in. lathe depends partly on the form of rest. Measure from centre to horizontal part of stand of rest, and double the measure for size of chuck, or, in other words, as large as the largest work the lathe will turn.—B. A. B.

**Monogram for Fretwork.**—E. MCN. (*Gateshead*).—In this design the "N" being the surname initial, it should be bolder than the E. and M. In order to render it so, it would be desirable to make it tall and central; but in this arrangement of lettering, which is both symmetrical and legible, the exigencies of designing preclude the use of an elongated N., so the prominence which cannot be obtained in height must be by breadth; hence an



**E. M. N. Monogram for Fretwork.**

expanded "N." becomes indispensable. Our correspondent would do well to devote a little extra time and attention when piercing this particular letter, and by keeping the saw clear of the edges, leave the face of it as broad as possible, thereby making it stand out just as bold in wood as it does in the pattern. With careful handling (which no doubt it will receive) the result will be highly successful and pleasing.—A. C.

**Magic Lantern.**—FOCUS CRIBUS asks two definite questions—first, where he can buy a magic lantern suitable for conducting a good Mission during the winter. To give a full answer would be to waste space, and a limited one seems invidious, the number is legion. If FOCUS CRIBUS can get a copy of the *English Mechanic*, he will find many advertised. One or two must suffice. Lancaster, Colemore Row, Birmingham; Riley Brothers, Bradford; Hughes, Brewster House, Mortimer Road, Kingsland Road, London; Noakes, South London Optical Works, Greenwich. From any of these he can get what he requires. Secondly, is it necessary to wet the screen when showing the lantern behind it, or what is the purpose of wetting the sheet? By wetting the sheet it becomes more transparent, the reason being the interstices between the fibres being filled, it becomes more homogeneous, so that less light is absorbed and more transmitted. When shown in front of the sheet it must not be wetted. A hard, even surface is required, which shall reflect as much light as possible, and transmit as little as possible. This latter plan is best, and is now generally adopted. Space is also utilised, which in a small room is always of importance.—O. B.

**Ink.**—S. W. (*Blackburn*).—Ink is theoretically tannate of iron dissolved or suspended in water thickened with gum. Inks, as now made, vary very much in their composition, and the gum generally used is dextrin, or "British gum," but for this sugar or glycerine is sometimes substituted. To test for the latter proceed as follows: Take a fair quantity of the ink, dilute it with water, and add basic acetate of lead solution, when a copious precipitate will fall, and must be filtered off. The filtrate will be yellow or nearly colourless, and contains the sugar or glycerine, if present; whilst the dextrin, tannin, and most of the other bodies are left in the precipitate. To the filtrate add a few more drops of basic lead acetate, and if there be no further precipitate, add carbonate of soda, which will precipitate the excess of lead used, which must be filtered off. The filtrate will contain the sugar and glycerine if either or both be present. Evaporate nearly to dryness, then shake up well with a mixture of two volumes of absolute alcohol and one volume of ether, and filter. Any sugar present will be left undissolved on the filter, which stand aside for a while. Any glycerine present will be in the filtrate, from which evaporate off all the ether and alcohol, when the glycerine will be left as a dense viscous liquid of intensely sweet taste. If a few drops be kindled they will burn with a blue flame and leave no residue; or, if a few drops be heated with acid sulphate of potash (bisulphate of potassium, or potassium hydrogen sulphate), vapours of acrolein will be given off, and can be recognised by their penetrating odour like that of burning fat, and their property of causing a flow of tears. Now return to your residue containing sugar, if present. Dissolve it in water, filter from any insoluble matter, and call the filtrate "Solution A." Put a few drops of an alkaline solution of copper sulphate into a test-tube, dilute with water, boil, and, when boiling, add a few drops of "Solution A." If there be any yellow or red precipitate of cupreous oxide on heating again, then sugar, in either of the forms called "glucose" or "invert sugar," is present; but if there be no precipitate, test for cane sugar as follows: Boil for a few minutes some of "Solution A" with one or two drops of hydrochloric (muriatic) or sulphuric acid, which will turn any "cane-sugar" present into "invert sugar," cool and neutralise the acid with carbonate of soda, and, as before, add a little of the solution thus prepared to some boiling dilute alkaline solution of copper sulphate. A yellow or red precipitate will prove that cane sugar was originally present. To make basic acetate of lead solution: Grind up in a mortar 1 oz. of litharge and 2 oz. lead acetate, with sufficient water to make the whole pasty. Now well boil the mixture with half a pint of water, filter, and keep the solution in a well-stoppered bottle. To make an alkaline solution of copper sulphate: Add an excess of potash to a few drops of copper sulphate solution, and then add a solution of tartaric acid until all the precipitate formed has re-dissolved. A little of this solution, diluted and boiled, should give no precipitate; if it does so, add more tartaric acid and potash, but take care to leave the resulting liquid considerably alkaline. Write again if you are not successful with your testing.—F. B. C.

**Makers of Bicycles.**—NIL DESPERANDUM.—There is no *best* maker of bicycles. Some of the best are: Singer & Co., Coventry; Premier Cycle Co., Coventry; St. George's Foundry Co., Birmingham; Humber & Co., Coventry and Wolverhampton. Any one of the above will supply a machine than which no better need be desired.—A. S. P.

**Ticket-Writer's Ink and Sable Pencils.**—G. R. (*Camberwell, S.E.*).—You can get all you require from Brodie & Middleton, Artists' Colourmen, Long Acre, W.C., who will procure you anything they may not have in stock, especially if you mention WORK.—H. L. B.

**Clincher Tires.**—G. A. P. (*Birmingham*).—The address of the makers of the Clincher Tire is Edinburgh. They can be had through any cycle maker or agent. Try St. George's Cycle Co., Upper Street, Islington, London.—A. S. P.

**Paper.**—W. H. (*Birmingham*).—Neither heavy or light carburetted hydrogen, nor hydrogen, which are the chief constituents of coal-gas, will affect prepared papers hung up in your offices sufficiently

for your purpose; but coal-gas generally contains a little sulphuretted hydrogen and carbon disulphide, which would turn black paper which has been soaked in an alkaline solution of oxide of lead. Boil up some litharge with potash, dip some blotting-paper in it, and hold it over a gas-jet to see if the gas supplied to you contains sulphuretted hydrogen or carbon disulphide. If it turns black, it will do for you; but always keep it moist.—F. B. C.

**Dutch Clock.**—AMATEUR.—After you filed up the 'scape teeth, the escapement was made shallower, and so you are unable to regulate it. Take out the 'scape wheel and put it in the "turns" or lathe, and file the teeth all the same length by holding the file steady while the wheel is revolving. Then make them all the same thickness at the tops, and replace the 'scape wheel. Now you will see the front hole of the pallets is in a strip of brass; move this round so as to put the pallets working deeper in the 'scape wheel. Have it as deep as it will go without catching on the tops of the 'scape wheel. You will then be able to regulate it with the ball and nut in the usual way.—A. B. C.

**Match-Lighting Clock.**—CLOCK.—I think I should try the old-fashioned lucifer matches. Have an arm to hold one, and fix up a piece of glass-paper, so that when the arm falls with the match on the end, it shall drag on the sand-paper, and so light it. Put a small weight so as to bring the arm and match down sharp. As regards the chemicals, I cannot help you, being very ignorant in that line. As to who would make them, I should advise you to try any of your local clock-makers, as, unless you wanted a quantity, it would not pay a big maker to make them. As it is, I have found making these curious clocks, etc., does not pay anyone. I have made several "fads" for amateurs, but find it neither pays them nor me.—A. B. C.

**Scene Painting.**—E. F. (*Hereford*).—I know of no instruction books on the art of scene painting. The only work I ever have known is one published about eighteen or twenty years ago by Mr. Lloyd, with coloured plates, price half-a-guinea; but I believe the edition is long since run out. If you have any taste for the art, you have only to follow out the simple instructions laid down in WORK. Study them well; you will soon overcome all difficulties. Should you require any aid to do anything you cannot master, if you will write, I will do my best to assist you.—W. C.

**De-magnetising Watches.**—DYNAMO.—Neither my friends nor myself know of the method mentioned by your friend. From your description of the process, I cannot understand how it was done. There may have been a small electro-motor in the box. One of my friends undertook to clean a lady's gold watch, and wore it for a few days to see how it would keep time. In attending to a strong magnetic machine, he got the watch magnetised, and came to me in a troubled state of mind about it. I advised him to place the watch on a rug and spin a powerful permanent magnet over it for a few minutes. This he did, and de-magnetised the watch. Watches may be de-magnetised by spinning them rapidly near a powerful dynamo, and withdrawing them gradually from its influence. Mr. Bottone undertakes to de-magnetise watches at a charge.—G. E. B.

**Connections of Electric Bells.**—ELECTRO.—Your sketch of connections for an electric bell and a three-hole indicator is quite right. One return wire will do for all of them; but a separate wire must go from each push to each indicator. Whenever in doubt, always sketch each circuit on paper, as you have done now, before you put up the bells. Our rules do not allow of a reply by post.—G. E. B.

**Hot-Water Fittings.**—R. J. (*Gainsboro'*).—The best books on hot-water fittings that I know of are published by Messrs. E. & F. N. Spon, 125, Strand, London. They will send you a list of them on application.—T. W.

**Electro-Magnet.**—STUDENT.—To ascertain the best magnetic results obtainable from your twenty half-pint Leclanché cells, connect them in series, and find the total internal resistance of the battery. Select a wire for the magnet which shall have a resistance equal to the resistance of the battery, and yet be long enough to place a large number of turns around the magnet core. By dividing the total E.M.F. of the battery by the total resistance of the battery and magnet circuit, you will find the ampèrage of the current flowing in the magnet coils; and, if you multiply the strength of the current by the number of turns of wire wound on the core, you will get at the magnetic strength of the current. You will, probably, get the best results from a pound of No. 26 silk-covered wire, wound on a ¾ in. core of iron, 8 in. in length, bent to the form of a horseshoe, having limbs 2½ in. in length, half a pound of wire on each limb. You will get very poor effects with this on a solenoid having an internal diameter of 3 in. Such a solenoid will require a very powerful current from a large Bunsen or Grove battery through many turns of No. 18 wire. To get alternating currents from a battery, you will need an automatic current reverser, worked by an electro-magnet.—G. E. B.

**Spoon- and Salt-Boxes.**—A GLASGOW BOY.—As a rule, I am particularly fond of receiving queries of such a nature as will tax my ingenuity to a noticeable degree, and would relish questions asking for anything short of perpetual motion and the philosopher's stone. Spoon- and salt-boxes certainly do not leave much scope for the display of talent; but as these articles are what you require, I must try and please you. The mention of spoons and salt brings up before my mental vision basins of porridge, disappearing as quickly as motion will allow down an accompanying throat. Do not think I am poking a bit of fun at you; for I am told that Scotch blood—of course, partly manufactured from porridge—runs in my veins. Indeed, the dearest relation I possess will try to convince me that I am related to the great Sir Walter! That troubles me little, for I trace my pedigree further back, and start with Adam; and thus claim relationship with the greatest men and women, dead or alive. Now to business. As you say you wish there were more designs of fretwork (although I am sure those given are numerous), I intend this article to be fret-cut. Now, it requires very little intelligence to see that salt would hardly contain itself within merely fret-cut boards; so (one way) rebate your side boards to a certain depth, leaving a narrow margin all round, and into this rebate sink your fretwork. A bottom board will complete the salt-box. The spoon-box will consist of four narrow boards, treated similarly

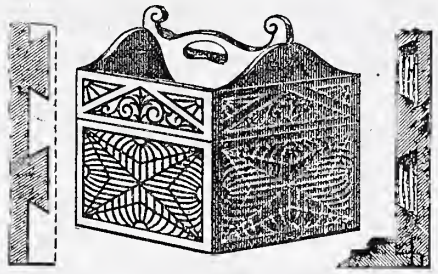


Fig. 4. Fig. 1. Fig. 5.

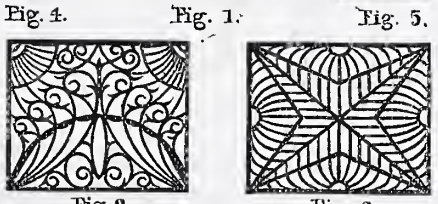

Fig. 2. Fig. 3.

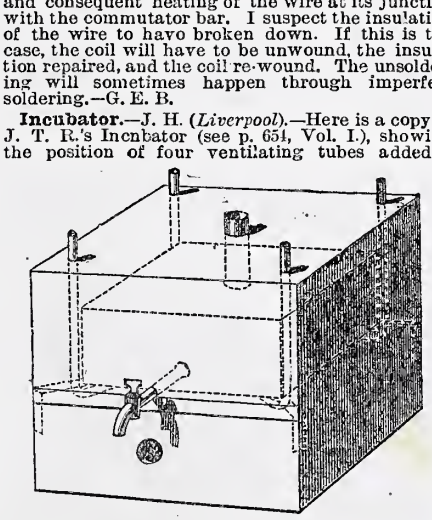
**Fig. 1.—Spoon- and Salt-Box. Figs. 2 and 3.—Designs of Fretwork for Box. Figs. 4 and 5.—Method of Dovetailing.**

to those of the salt-box, and a bottom board, with a division across the middle, shaped to serve as a handle. The spoon-box will be hinged on one side to the salt box, both being secured by a lock or a hook. If you wish for a strong box, dovetail sides together, as in Figs. 4 and 5, and join bottom board, as in Fig. 5. Concerning sizes I can say nothing, as I know not whether you wish to stock sufficient salt for a day or a year. I have given you two or three designs for fretwork, but I make no pretence of their being anything nice, as other pencils can manipulate this branch of art better than mine can. If either suit you, however, and you wish to enlarge them, as you have all the past numbers of WORK, you will find how to do so by reading the Music-Stand articles by O. B. and myself. I cannot reply definitely to your other question, but must advise you, as I have just advised another correspondent on another subject—be patient.—J. S.

**Unsoldering of Dynamo Wires.**—DYNAMO.—If the wire becomes unsoldered from the segment of the commutator only, there is some fault in that coil which leads to an excess of current through it, and consequent heating of the wire at its junction with the commutator bar. I suspect the insulation of the wire to have broken down. If this is the case, the coil will have to be unwound, the insulation repaired, and the coil re-wound. The unsoldering will sometimes happen through imperfect soldering.—G. E. B.

**Incubator.**—J. H. (*Liverpool*).—Here is a copy of J. T. R.'s Incubator (see p. 651, Vol. I.), showing the position of four ventilating tubes added.—



**Incubator.**

B. A. B.

**Wood-Block Surface.**—ENGRAVER.—The finely polished surface must be removed by the application of Bath-brick, finely powdered and well wetted. This should be vigorously rubbed over the block until the shiny appearance is got rid of. Then clean the surface, and apply, as evenly as possible, with a broad sable brush, a thin wash of white—at first it will be found difficult to apply the paint equally and evenly, but practice will soon obviate this. It may be necessary to pass the now empty brush two or three times over the block, in alternate directions, to distribute the white more equally.—W.

**Book on Electric Lights and Electric Bells.**—IGNORAMUS.—I do not know where you can get a cheap book, combining information on "electric lights, electric bells, and the fitting up of the same, and explaining the meaning of the technical terms, ohms, volts, watts, ampères, etc." The cheapest source of information on these subjects is this little paper, which you can get for one penny per week. In Nos. 12, 18, 20, 27, 31, and 33, you will find information on electric bells; in Nos. 76, 82, 89, 92, 94, 97, 99, 101, and 104, you will find information on electric lights. The meaning of technical terms has been given several times in "Shop."—G. E. B.

**Unbrazing.**—T. B. (*Islington*).—It is impracticable to unbraze many articles, as it would certainly spoil them; but you can manage it in the case you mention. You must heat the handle to the melting point of the spelter again, assisting it with a little powdered borax. You can then take it apart. If it is pinned or riveted in any way, the pins or rivets must be drilled or punched out first. The brazing in of a new handle is not a very difficult matter. Get the socket and the handle perfectly bright and clean before attempting to braze, and you will be sure to succeed; especially if you will take the trouble to refer to the indices of Vols. I. and II. of WORK, where you will find that there has been considerable information given on brazing both by myself and others.—R. A.

**Drawing.**—P. B. (*London, S.W.*).—I do not know of the existence of classes held specially in mediæval ironwork; but if you master freehand, you can easily practise the drawing of ironwork. "Metal Work and Its Artistic Design," by M. Digby Wyatt, is a good book, published by Day & Son, Lincoln's Inn Fields. You can go to South Kensington and draw from actual work, of which there are some very fine specimens, both ancient and modern, in the Wrought Iron Gallery.—J.

**Conical Bellows.**—R. K. B. (*Woolwich*).—It is not an unknown occurrence for incompetent workmen to find fault with their tools. We cannot be expected to supply brains as well as information. In all cases of merely written directions, much is, perforce, left to the ingenuity of the workman. Those alluded to have been successfully carried out by some of our readers, who were, possibly, more apt workmen than R. K. B. It would occur to most people of average intelligence, before cutting up valuable material, to make a rough pattern in paper in order to practise the folding and the pinching up of the corners, which certainly require a little knack; and which experiments—tried on the leather, etc.—would, in all probability, spoil it. Better try again.—D.

**Instantaneous Camera.**—G. B. (*Stoke*).—If you refer to back numbers of WORK, you will find information that may be of use. A camera of the kind you require can be purchased at such a low price (21s.), that, considering the probable result, it is almost better to purchase one, with lens, shutter, and all complete, than make one yourself. All of our well-known opticians supply lenses suitable for these cameras; and as to dry plates, any photographic material dealer can supply you; also, many chemists and druggists stock them.—D.

**Cold Brazing.**—G. A. M. (*Chorley*).—I have never tried to braze a band saw cold, having but little faith in cold brazing, therefore I cannot say whether it would answer, but am of opinion it will not, the strain being so great, and so much bending and straightening of the saw; but will give you receipt for making cold brazing, etc., so that you may try for yourself. Mix in a lead bottle 1 oz. of fluoric acid and 1 oz. of oxy-muriatic acid. See that the parts to be brazed are perfectly clean and free from grease or oil, and put a chalk mark on each size of braze. The above mixture will keep good in the bottle about six months. If any reader who has had experience in cold brazing will write briefly on the subject, I have no doubt but that the Editor will gladly insert it in the "Shop" corner—stating what he thinks is the best way to proceed, and with what success he has met. Such information may benefit more than one of his fellow-readers. I might add that I am of opinion that there is no simpler method of brazing band saws than with bright, hot and black, or dull red-hot, tongs, as described in back numbers, and feel confident no stronger braze can be made in a band saw.—A. R.

**Toy Manufacturer.**—GAMESTER.—For any new toy, you cannot do better than consult Jacques and Son, Hatton Garden, London, E.C.

## III.—QUESTIONS SUBMITTED TO READERS.

*** *The attention and co-operation of readers of* WORK *are invited for this section of "Shop."*

**Opal Glass Letters.**—RUBRIC writes:—"Would any reader do me the kindness of supplying the information how the above are cut out? Some say they are not cut out at all, as appeared some time ago in your paper. Others say they are cut out by emery powder and iron wheels. As there seems

to be such various opinions, any reliable authority would be gladly welcomed."

**Ventr loquism.**—DOWLAIS will be glad to know of a good, cheap book on Ventriloquism.

**Wooden Monogram.**—MUGGINS writes:—"Will any wood-worker show me how to put the initials E. M. C. on a box?"

**Panel Gauge.**—APPRENTICE writes:—"Will any reader oblige by letting me have, through 'Shop,' a drawing and size of a handy and also a nice-looking panel-gauge?"

**Pottery and Porcelain.**—T. H. L. (*Dublin*) writes:—"Will any reader inform me what are the best books pointing out general characteristics of the various kinds of china, etc., such as Oriental, Dresden, Spode, Crown Derby, Wedgwood, Worcester, and showing marks and stamps which distinguish same?"

**French Medal Glue.**—CONSTANT READER writes:—"Will any reader of WORK kindly inform me as to the best methods of: (1) Preparing French glue to use for gluing wood together. (2) Keeping a quantity ready for immediate use where about 28 lbs. are used per day. (3) Also, does glue lose any of its intrinsic qualities by being kept boiling hour after hour?"

**Magic-Lantern Oil.**—J. D. (*North Wales*) writes:—"Will any reader of WORK tell me the name of the best paraffin oil suitable for magic-lantern use, or if, by the addition of any chemical, a most brilliant light may be had? I should also like to know if there is any other oil better than paraffin for same use."

**Gilt Frames.**—EDWARD writes:—"I shall be glad of views as to the best thing for cleaning gilt frames that are slightly soiled."

**Saw-Hammering.**—J. S. (*Keighley*) writes:—"Will any reader say which is the proper pattern for an anvil for saw-hammering? Should the face be perfectly flat or round? Also as to gulleting saws: which is the best method, using emery wheels or stones, or the fly-press, for punching-out? Give advantages of each system."

**Launch Screw.**—W. L. H. (*Swindon*) writes:—"Will some kind reader answer the following questions in 'Shop?': (1) What is the best size for a screw to drive a small launch at a maximum speed with economy (launch, 22 ft. long and 45 ft. beam)? I should like to know the width and breadth of blades for three-bladed and two-bladed propeller. (2) Where is the best place to buy a small injector, and probable cost thereof, for a 2-horse power vertical boiler?"

**Sledge.**—W. B. S. (*London, N.W.*) writes:—"Will any reader please tell me how to make a sledge?"

**Perfumery.**—A. H. K. (*Pendleton*) writes:—"I should be glad if any reader could tell me through 'Shop' whether there is a practical book on perfumery, and where obtainable."

**Mandoline.**—H. D. (*London, S.W.*) writes:—"I wish to know whether any of your readers could send me a complete sketch and description for making a canoe- or pear-shaped mandoline."

**Open Sailing Boat.**—G. A. (*Hornsey, N.*) writes:—"Will anyone tell me the proper proportions for a 19-ft. boat—that is to say, the width at the widest part, the depth at the stern, midships, and the stem? I propose to make the skin of pitch pine; the stem, transom timbers, and keel, of American oak. Can I do better?"

**Fire Engine.**—W. L. (*Dalston*).—If you want to know how to load the L'Extineteur Fire Engine No. 4, you cannot do better than write to W. B. Dicks & Co., London, S.E.

**Water Motor.**—WATER MOTOR writes:—"Not having seen anything of the sort in the pages of WORK, I should be greatly obliged if any correspondent would tell me through 'Shop' the particulars and dimensions of a water motor to be driven by water from town main to give about ¼-horse power—to use as little water as possible. There is a good pressure of water from main, and I want to drive a small 50 c.-p. dynamo."

**Bar Bullion.**—G. C. (*Brighton*) writes:—"Can any reader kindly inform me where the 'bullion dealers' buy their silver, or where it can be bought, in bar, at the quoted market price? It is of no use going to the bullion dealers themselves, as, of course, they must have a profit. Is there not a bullion office at the Bank of England?"

**Glass Painting.**—J. A. B. (*Camberwell*) writes: "I wish to ask any experienced reader who understands glass painting which are the principal transparent colours connected with this art."

**Illuminating.**—G. S. (*Gateshead on-Tyne*) writes:—"I have lately been attempting some illuminating of letters, but have not been very successful—especially with my monograms. Would it be asking too much of any reader to give me a monogram for illumination of the letters E, H, S? I got a very good E in one of the back numbers of WORK, but I have not made E, H, S, to my satisfaction."

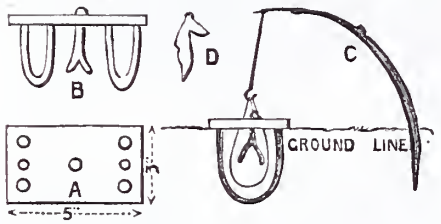
**Vacuum Pans.**—VACUUM PAN writes:—"Will any so well-informed give me the names of any good English works on Vacuum Pans, and their usage?"

## IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Inlaying.**—C. W. S. (*Sydenham*) writes, in reply to A. E. (*Wandsworth*) (see p. 446, No. 132):—"If A. E., or any other reader of WORK, will call at 33, Stanton Square, Lower Sydenham, I shall be pleased to show him my method of inlaying, with specimens of materials used. Call before twelve noon."

**Paraffin Barrels.**—J. M. C. & Co. (*Nottingham*) write:—"In reply to PARAFFIN (see p. 526, No. 137), *re* 'Measurement of Paraffin Barrels,' the gross weight is taken, the tare of the cask deducted, and the remainder divided by 8, shows the number of gallons—as, for example, 3 cwt. 2 qrs. 26 lbs. gross; 2 qrs. 21 lbs. tare. Now the gross weight equals 418 lbs. Deducting the tare, 77 lbs., from 418 lbs. leaves 341 lbs. This divided by 8 (the number of lbs. in a gallon) gives 42 gallons and 5 pints. The mark, '120 test,' refers simply to the flashing point of the oil, which may be subjected to 120 degrees of heat before it will take fire, and is the degree of safety prescribed by Parliament. Any oil firing at a lower temperature would not be passed as 'paraffin,' but would come under the term 'explosive,' and be classed with benzoline and such inflammable substances."

**Wooden Mole Traps.**—E. R. D. (*Sherborne*) sends the following method of making mole traps in reply to J. J. (*Cumberland*) (see p. 492, No. 135):—"Cut out as many pieces of wood, ½ in. thick, with eireular saw as at A; bore five ½-in. holes with drill in the lathe, and two ½ in. holes for the wire; drive



Wooden Mole Trap.

in a wooden staple at each end, made of green hazel or other suitable wood, split flat side inwards; fit a Y piece at B for the mole to push out with his nose, which lets the end of a piece of string attached to the spring stick, C, fly up, and draws the two fine wires tight, and the mole dies. Two hook sticks, D, should be placed on each side to hold the trap down in the tunnel."

**Screwing Tackle.**—T. B. B., JR. (*Manchester*) writes:—"In reply to the letters of AN ADMIRER, T. S., and other correspondents, I may say that the article in question on 'Taps and Reamers' was intended as the first of a series on screwing tackle generally. Failing health, however, prevented me from continuing them; but I will resume them as soon as possible. I think if T. S. examines his screw-plate closely he will find that the thread on one side has been reduced by slightly enlarging the hole. This side is the proper one with which to start cutting a thread. The threads, too, at all events in the larger sizes, are backed off for clearance, so that they will only cut one way. This will settle which is the starting side of the plate. I cannot tell what all the holes in his screw plate are for without having seen it. Probably there are two holes for the smaller sizes and three for the larger. One hole of each size will cut a full thread. The other hole or holes of each set may have been enlarged, so that they do not cut the full depth, and so are easier to start, and are not so liable to twist the pin, being screwed. Some of the remaining holes may be duplicates of the commoner sizes. I cannot say exactly, but I have made them that way. As for his difficulty in tapping shallow holes (or rather, comparatively shallow), I know it is rather awkward; but if the taper tap will not start the thread, the second one (on which the thread is only backed off a little) should do so. The holes, too, may be opened out a little at the top, unless it is necessary for the thread to come to the top. This would materially assist the starting of the tap."

## V.—LETTERS RECEIVED.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—T. E. W. (*Wolverhampton*); L. J. G. (*London, W.C.*); A ZINCWORKER; JACK FROST; T. F. (*London, S.W.*); AMATEUR; W. J. (*Newcastle-on-Tyne*); LLEWELLYN; W. L. (*Wolverhampton*); DULCIMER; C. F. C. (*Oldham*); J. M. (*Derby*); T. R. B. (*Newcastle-on-Tyne*); E. C. S. (*Bickington*); A. C. R. (*Cardiff*); G. A. S. (*Edinburgh*); S. W. N. (*Lonsfield*); A SUBSCRIBER; S. C. W. (*Bristol*); CAB; ANXIOUS ENQUIRER; W. P. (*Dundee*); M. S. (*Bristol*); B. A. (*Scarborough*); G. T. (*Hollinwood*); E. F. B. (*Liverpool*); APPRENTICED LOCKER; T. P. (*St. Leonard's*); G. A. W. (*Holloway*); R. Y. (*Burdett Road*); D. M. S. ## AN ATMOSPHERIC INCUBATOR: HOW TO MAKE AND WORK IT.

BY LEGHORN.

INTRODUCTION — GENERAL PRINCIPLES — ADVANTAGES — CASE — FITTINGS — REGULATOR — LAMP — WORKING — CONCLUSION.

*Introduction.*—My object in writing this paper (in fulfilment of my promise in No. 99, Vol. II., to describe a simple and reliable atmospheric incubator) is to help those who help themselves.

The ancient Egyptians, we are told, hatched chickens artificially, so that we may presume incubating machinery is no new thing; but the varying success following its use, together with its somewhat prohibitive price, has not had the effect of bringing the artificial method into general use until quite recently. Since, however, the introduction of the "hot-air" variety, an impetus has been given to poultry raising generally, and machines are now to be had, the results from which make "poor Biddy" take quite a back seat.

Whatever your object in poultry keeping—eggs or table birds—the grand secret of success is to hatch your chickens at the right time, so as to ensure a steady and constant supply all the year round. Those who keep only non-sitting varieties or, having limited accommodation, can keep but few birds, generally have a difficulty in finding a hen willing to undertake maternal duties in the early months of the year—a necessity if winter eggs are wished for—so that, for raising early chicks and ducks for laying purposes, the show pen, or for market, the possession of a reliable incubator must necessarily prove a great boon. Now a good machine with a pedigree costs money, and the average amateur poultry keeper, as well as some of his professional brethren, does not care to lay out much money in the purchase of such, and consequently gets only late-hatched birds, which do not make the return they should. "Poultry don't pay," used to be, and still is with some, a familiar croak; but I am glad to say we are beginning to find out that poultry *does* pay, and pay well, IF—put this in big type, please, Mr. Printer—they have proper attention; in fact, no stock pays better if *intelligently* managed.

In this paper it is my intention to place within the reach of all who possess but a small amount of mechanical skill the outcome of a long period of study of the principles and practice of artificial incubation. From the amount of correspondence I have received, I feel sure the subject will be a pleasing one to many readers of WORK, and if I can help any lame dog over a stile I shall not have put pen to paper in vain.

I purpose giving instructions for a machine nicely made and properly fitted—my motto always being, "What is worth doing at all is worth doing well;" but, of course, details of finish and materials must be left entirely to the individual worker.

*General Principles.*—Josh Billings says: "The principal bizzness for an abel-boddyed hen iz tew lay eggs, and when she haz laid thirty-six ov them, then she iz ordained tew set still on them until they are born; this iz the way young hens fust see life."

This is evidently something of it, but we must look a little farther into the subject. Let us for a moment inquire into the principles of incubation. At first sight it would seem that all a hen does to the eggs is to keep them warm during a certain period. However, this is not all. In the natural order of things, the bird would make her nest on the ground, and the heat of her body would draw moisture from it; also, during her morning ramble, her breast feathers would get saturated with dew, thus providing more moisture: and as a hen selecting her own nest thus, rarely fails to bring off a chick for every egg, it follows that moisture plays a very important part in the process of incubation, natural or artificial. In building a machine to discharge these functions, the nearer we copy nature the better results we may expect. We need, therefore, to have the bottom of our machine in the form of a nest—the reason for this will be seen later on—and to supply a moist heat centrally and from *above* the eggs, kept as near the natural heat of a hen's body as possible.

The simplest method of supplying the necessary heat is by means of a lamp placed under the centre of machine. The heat arising from the combustion of the oil enters the machine by a suitable flue, and is radiated all over the hatching chamber, in its course passing over a tray of water, for which hot air has a great affinity, and finally escaping by a series of holes in the lid. Thus we have a continual flow of hot, moist, fresh air. "But," I hear someone say, "won't the fumes from the lamps kill the germ of the chick?" I answer, "No; if the lamp is kept burning properly, with the wick regularly trimmed, there should be no smell whatever, burning even the cheapest oil, which, however, I do not recommend."

In this variable climate of ours, it is impossible to keep a constant temperature in the egg chamber without some automatic means of regulation, the heat inside fluctuating according to the temperature of the atmosphere. We need, therefore, to arrange for a larger supply than necessary, letting off the surplus heat by a suitably arranged valve, actuated by a sensitive regulator. As the heat, in the course of its passage through the machine, will naturally lose some of its intensity, we need to arrange that the outer layers of eggs are higher in the hatching chamber than those nearest the centre. This is accomplished by means of the dished bottom previously mentioned. This also serves another purpose. If you watch a hen after returning to her nest from her daily feed, etc., you will notice that she is very busy for a few minutes, turning her eggs over and altering their relative positions. The dished bottom enables this to be done easily, for, by simply taking the layer nearest the centre of the machine and placing them at the edge of the nest or egg-tray, the others will naturally roll into their places. The reason for this changing will be discussed later on, when we come to the working. We need also to follow nature by allowing the eggs a periodical airing, which they would naturally get during the hen's daily absence.

Having now discussed the principles of incubation, we will just summarise a few of the advantages, and then proceed to the construction of the machine.

*Advantages.* — The advantages of the machine to be described may be estimated thus: Its portability, no cumbersome and leaky hot-water tank, no heavy egg-drawer with consequent loss by concussion and breakage; it can be started in five minutes after the regulator has once been adjusted; it keeps a perfectly even temperature; the consumption of fuel is small—less than half what a hot-water machine of same capacity would require; and with proper attention—all other things being equal—it will hatch every fertile egg. I hope the work of construction and the after operations may be the source of much pleasure to such of our readers who keep poultry for pleasure, prizes, or profit.

*Construction: The Case.*—On reference to the diagrams on the front page of this number, it will be seen that the apparatus consists essentially of a box with a hinged lid, standing on four legs. Fig. 10 gives a view of the finished machine (from a photograph); Fig. 2, a complete cross section—that is, as if the machine were cut in halves through the centre from back to front; whilst Fig. 1 gives a section of the upper portion only, cut lengthways.

For this incubator, thirty-six egg size, we shall want a box 17 in. long, 14 in. wide, and 9 in. deep, all outside measurements. The wood may be pine, deal, or any harder wood the fancy of the maker may direct; but whatever is used, it *must* be dry and well seasoned, or it will probably shrink and crack under the heat to which it will be subjected. For this reason it will be advisable to select one of the softer woods as being more likely to be well seasoned. The material forming the sides and lid should not be less than $\frac{3}{4}$ in. in thickness, whilst that for the bottom may be $\frac{1}{2}$ in. It would be well, perhaps, if I give here a list of wood required. For the front and back we shall require two pieces 17 in., and for the ends, two pieces 14 in. long by $7\frac{1}{2}$ in. wide; for the bottom, one piece 17 in. by 14 in.; for the top (if framed), two pieces $18\frac{1}{2}$ in., and two pieces $15\frac{1}{2}$ in. long by $3\frac{1}{2}$ in. wide. For the centre frames, one piece 31 in. by 3 in.; for the fillets, one piece $25\frac{1}{2}$ in. by $2\frac{1}{4}$ in.; for the legs, 4 ft. of $2\frac{1}{2}$ in. by $2\frac{1}{2}$ in.; and for the leg blocks, a piece of, say, oak or mahogany, 6 in. by 6 in. These are neat, finished sizes, so, to allow for a little waste, we had better procure, say, 12 ft. of 8 in. or 9 in. by 1 in. (Inch boards really only hold about $\frac{7}{8}$ in. thick, so by the time both sides are planed it will be about the right thickness.) Also get, say, 4 ft. of 7 in. by $\frac{5}{8}$ in., 4 ft. of $2\frac{1}{2}$ in. by $2\frac{1}{2}$ in., and the piece of hard wood $6\frac{1}{2}$ in. by $6\frac{1}{2}$ in. Having procured these, planed and cut them to size, we will now proceed to the joining. The sides should preferably be dovetailed (for description of various dovetail joints, see an article by Fred. Crocker in page 389, Vol. III., or No. 129), but may be merely butted and nailed, or jointed and cross-nailed, as shown in Fig. 5. This makes a fairly strong joint, and the rebates in back and front may be cut with a tenon saw and wide chisel, or a rebate plane will make matters true and square. If, however, nice work is aimed at, dovetailing is by far the best method of jointing, and, if my readers are not carpenters enough to do it themselves, a few shillings expended in getting it done will not be wasted. The sides having been joined, we will now fit the bottom, which should not be permanently secured until the centre frames are fixed (see *Fittings*). Before fixing the bottom, cut a 3 in. square hole exactly in the centre. This is for the lamp flue. Now with a gauge or pencil correctly mark a line all round the box, $1\frac{3}{4}$ in. from the top. The lid now demands our attention. As will be seen from the plan (Fig. 4) and sections (Figs. 1 and 2), it consists of a frame with a centre rail, and contains two glass panels (G). These are very useful, especially during hatching time, to see how matters are progressing without opening the lid. This glass should not be less in substance than what is known in the trade as 32 oz. sheet or pieces of plate glass, which

is about ¼ in. thick, would be still better. The frame should be mortised and tenoned to make a nice strong job, but a simpler plan, though not nearly so good, would be to halve the joints and secure them with brass screws from the under side. It may, of course, be solid, but, if this plan is adopted, it should have a lining of felt and sheet zinc, or it would, in all probability, crack with the heat. The top now being ready, nail it to the sides of the box, and fixing the case, if possible, in the vice of a carpenter's bench, proceed to divide the lid from the body by sawing round the line previously marked. Now take out the saw marks with a smoothing plane, and hang the lid with a pair of 1¼ in. or 1½ in. brass butt hinges, using brass screws (iron would rust).

Now mitre a 2 in. architrave moulding round the bottom, and a 1¼ in. panel moulding of similar section round the lid under the projecting top, or a plain plinth may be affixed to the bottom and a small hollow run round the top, as shown on the right-hand side of Fig. 2, or the top and bottom may be rounded off or left square, as on left-hand side of same figure. In this latter case the bottom should project ¾ in. over the sides instead of being flush, as previously described. Before fixing the top, a hole 2 in. in diameter should be cut in centre of middle rail (see D, Fig. 4, also sections), and round the framing of lid a series of ⅜ in. holes (V) equidistant from each other, and midway between the edge and the glass, should be bored with a centre-bit—boring from both sides in order to cut the holes clean. These are for ventilation. Now procure two squares of glass 9¼ in. by 4¾ in., and fix in place with small beads secured with needle-points or fine brads. Now, having prepared your blocks of hard wood, take them, with the four pieces for the legs, to a wood-turner, and get him to turn the legs to pattern, and cut a thread on the top stud and a corresponding thread to fit in the blocks. This will cost about 1s. or 1s. 6d., according to the conscience of the turner. Now fix the blocks in position as shown, screw in the legs, punch in all nail heads, stop the holes with putty, and give all a good glass-papering. It can now be painted or stained and varnished to taste, when it will be quite an ornament in any room of the house. A pair of brass side hooks fixed to the front for fastenings completes the case, and we will now proceed to the fitting up.

*Fittings.*—On reference to the sectional drawings (Figs. 1 and 2), also to plan (Fig. 3), there will be noticed an arrangement of double frames (C F) fixed in the centre of the machine, to which is affixed the lamp flue and evaporating tray. To be more explicit, the arrangement consists of two lidless and bottomless boxes made of ⅜ in. wood, 3 in. high, the outer one 5 in. square, and the inner one 3¾ in. square—both outside measurements. The smaller of the two is fixed, by means of fine brass screws, exactly over the square hole in the centre of the bottom; the larger one is fixed outside the other, leaving a ¼ in. air space all round. The object of this is to prevent the heat from striking through direct to the eggs nearest the centre of machine. These having been fixed, secure the bottom of case to the sides permanently by means of brass screws. Now take the remainder of the ⅜ in. wood, which we have already planed up, and cut to shape eight fillets, two to each pattern (see Figs. 6, 7, 8, and 9). When prepared, they are to be fixed with brass pins or brads all round the bottom of case and centre frames, and in the positions indicated by the corresponding numbers on plan (Fig. 3). These complete the wood fittings. We now require a sheet of perforated zinc a little larger than the inside measurement of the case). Cut out a portion corresponding in size to the centre frames, and then cut and shape the zinc to fit on the fillets, thereby forming the dished bottom, egg-tray, or nest (Z, Figs. 1, 2, and 3) previously mentioned. Fix this bottom down with brass escutcheon pins to the fillets, first boring the holes with a suitable bradawl, and then forcing the pins home with a piece of wood, so as to be easily withdrawn when required for cleaning purposes. Out of sheet metal—copper recommended—make the lamp flue (F) and the evaporating tray (E). Through the bottom of the latter solder a piece of small brass tube (O, Fig. 2) to act as overflow pipe. Over the bottom of this slip a piece of rubber gas tubing to convey the waste water to a suitable receptacle (O P, Fig. 2). To the top of lamp flue fix, by means of rivets, three narrow strips of copper, forming a tripod, shaped to hold the radiating disc (R D, Figs. 1, 2). In order to make this quite clear, I have, in Fig. 11, sketched the top of flue, showing tripod and disc. This disc should be made of a piece of stout steel metal, and have affixed to it tightly by a single rivet a short arm as shown, with a small hole drilled in its extremity to serve as a guide for the regulator rod (R R), of which more anon. A second disc (R O D), but smaller, should also be provided, and hung by cross straps from the top of flue, in order to throw the heat passing upwards against the sides of evaporating tray, thus heating the water contained therein. A metal cup (C, Figs. 1, 3, and 4) must now be provided, and a piece of brass tube soldered into the bottom at the back to convey the water into the evaporating tray. These two fittings should be made of copper, and it will repay the worker in the end to have them made by a coppersmith, as there must be no soft soldering about them. They are also the parts subjected to the most wear and tear. Tinplate will not do on any account, as sooner or later it would only lead to trouble; therefore avoid it. The next fitting to claim our attention is the water tray (W). This may be made of zinc, and needs no special description beyond saying that it is a rectangular vessel, supported on two brackets of iron or wood secured to the side of case. A small brass tap, costing about 1s., should be soldered near the bottom at the right-hand side of front, and serves to regulate the supply of water dropping into cup (C).

The next item on the programme is the damper (D). This may be built up of sheet metal, but is better as a brass casting. It consists of a bent bar, say, ⅜ in. wide and ⅛ in. thick, with a circular enlargement at one end 2½ in. in diameter, and a smaller but thicker enlargement at the other. This should be hollowed out and filled with lead as required to adjust the balance, so that the widest end is just slightly the heavier of the two. A cross-bar occupies a central position in its length, the ends being reduced and filed to a knife edge. Two brackets, with a round hole in each, are fixed on either side to the top of the case, forming the fulcrum on which the knife edges work. A small flange, ½ in. deep, is now to be fixed over the circular hole in cross-rail of lid, and the damper adjusted until it covers the opening in the flange. After the regulator is fixed, carefully note where the lifting-rod (R R) engages with the bar of damper, and at this point drill a hole and fit a small milled-headed screw (S). When fitted, a small disc should be soldered to its point, in order to catch the end of the lifting-rod of the regulator. By means of this screw the final exact adjustments are to be made. A simpler arrangement, though not nearly so good, would be to make the damper lever of wood. The cross-bar could be of wood also, having a couple of needle-points driven in, one at each end, which might work in the slots of screw heads, screwed in the lid.

*Regulator.*—This, as will be seen by reference to Fig. 2, consists of a bent glass tube (R) of about ½ in. calibre, bent in the form of the letter **J**. The shorter limb is sealed over with the blowpipe, and in the sealed end, imprisoned by a column of mercury (M), is contained a volatile fluid (S E); preferably dilute sulphuric ether in the proportion of 3 parts of ether to 1 of alcohol. (N.B.—Water will not mix with ether, so do not try it). This fluid, boiling at a low temperature, gives off a vapour in proportion to the amount of heat present, and, being imprisoned, forces the mercury column round into the longer limb. This in turn engages with a small float or plunger (P) resting on its surface, carrying a rod (R R), which in its turn actuates the damper (D), impinging on the small disc at the end of adjusting screw (S), and allows a portion of the heat to escape. As the temperature falls, the damper resumes its normal position, rising and falling according to the variations in the temperature. In practice, however, it will be nearly always open, and should be adjusted so that the damper stands about ⅛ in. clear of the flange, thus allowing for decrease as well as increase of heat. Now, to get the ether and mercury into their proper positions is rather a troublesome job to the tyro, but to the initiated it is as easy as "eating pie," and is easier shown than described. However, having procured your tube, pour into it sufficient mercury to fill not quite half its length. By gently tilting the tube thus, \, force out all the air, so that the mercury entirely fills up the short arm. Now pour about three-quarters of an inch of ether on the mercury, and by gently tilting in this direction, ⌐, lodge about half the fluid above mercury at the sealed end. Ether being of lighter specific gravity than mercury, will assume the uppermost position. Bring the tube to an upright position, and with a small piece of rag or sponge soak up the surplus liquid now remaining in the open end. Slip the rod through the hole in the guide-arm attached to radiating disc, and adjust as necessary, so that the plunger slides easily and freely in the tube, and at the same time engages, when rising, with the small disc of adjusting screw. To know the exact temperature the machine is working at a thermometer will be necessary, and should have a bent tube in the form of the letter L (see T, Fig. 2), the bulb being inside on a level with the upper side of eggs, and the scale from about 90° to 120° Fahr., reading outside. To protect the thermometer it must be encased, as shown, with a piece of brass tube fixed in the front.

*Lamp.*—Now we come to the heat supply. It is not absolutely essential that a lamp should be used. Gas may be employed if more convenient, only it needs carefully watching to note when pressure in the main is increased, as it always is towards night, or you may get more heat than the regulator can master. Watch should also be kept

that the supply is not shut off for repair of mains, etc., without being noticed. If a lamp is used, these precautions are unnecessary, and can, after the first day or two, be left to take care of itself for twenty-four hours at a stretch. The best form of lamp to use is one of the round burner variety, known as "kosmos," taking an inch wick. The burner and screw collar can be purchased at most respectable oil shops for about 1s., and should be fitted to a square tin reservoir as shown in Fig. 2, a screw cap being also provided for filling. If made to size, as drawn, it will hold enough oil for two days' supply in the coldest weather.

All the sketches—with the exception of Figs. 5, 10, and 11—are drawn to a scale of 2 in. to the foot, or one-sixth full size, so that if any measurement is multiplied by 6, the exact size will be obtained.

*Working.*—We will now suppose the machine finished, and ready for a trial run. It will be well to run it empty for a few days in order to understand its working and to get the temperature set and regulator adjusted. The machine should stand, if possible, in a room with a fairly even temperature (the bedroom is a capital place, if the lady members of the household do not object), out of the way of draughts, and as far from the reach of loud noises and jarrings as possible. The quieter its surroundings the better. The situation having been selected, fill the lamp with oil of good quality, costing about 1s. per gallon. Avoid cheap oil; for our purpose it will be the dearest in the end, being very deficient and variable in heating power. Trim the wick squarely with the top of the burner, light, and turn up until the flame is about level with, or but slightly above, the constriction in the chimney. Fill the water tray with tap water (warm in cold weather), and turn the tap so that it supplies a full drop per second, remembering that, as the water gets lower in the tray, the slower will it drop from the tap. A piece of muslin placed over the tray and water-cup will keep out dust, etc., which might choke the tap and pipes. Take out the regulator rod, and watch the thermometer until it registers from 104° to 106°. Now note the position of the mercury column in the regulator tube, and cut the rod to its approximate proper length, insert in place, and make final adjustments with adjusting screw (s). As regards the proper heat to work the machine at, a little difference of opinion exists, but it is pretty generally conceded that it lays between 104° and 106°. I have had good results with the latter, but if eggs at various stages of incubation are in the machine together, the former figures will be preferable. Having mastered the details of working, *and not before*, place a few ordinary eggs in the machine, and proceed to business.

One word of caution: Do not put a batch of valuable eggs in for the trial run, as incubators, like everything else, want understanding before the best results can be obtained, and it is considerably within the range of possibilities that the first lot may not prove an unqualified success, although the experience gained should stand you in good stead. Josh Billings says, "The hen is a darn phool;" but this remark does not apply to this "tin hen," as incubators have been called, and any failure should not be rashly laid to its account. The eggs being in, and all working satisfactorily, we shall need to trim the lamp once every twelve hours by carefully removing the charred portion of the wick with a duster, also replenish oil and water as may be necessary. Once a day, morning preferably (when the lamp is trimmed will be a seasonable time), open the lid of machine for a short time according to the state of the weather—say fifteen minutes in cold weather, and twenty in warm—to give the eggs an airing; and also turn them and alter their position as before described. The reason for this is that the germ always floats on the top of the egg, and if kept in one position would probably stick to the shell, and thus cause the death of the embryo chick. No notice need be taken of the temperature in the egg-chamber for an hour after the daily airing, after which time, with the lamp burning properly, it should have resumed its normal temperature. Provided the eggs were fresh—and I may as well say here they *must* be as fresh as possible (if taken direct from the nest to the machine, all the better), as stale eggs cannot but produce unsatisfactory results — we may, towards the end of the twentieth day, look for signs of the eggs chipping, and may possibly hear the chirp of the chicks some hours before the shells are "starred." Avoid opening the lid of machine at all times, any more than is necessary, and especially at hatching times. If no shells are "starred," the eggs may with advantage be placed in a basin of water heated to 100° Fahr., placing them in gently, so that they are not entirely submerged. The live chicks can now be easily distinguished by the capers they cut, the struggles of the chick trying to extricate itself giving the motion. After a few minutes' soaking—being careful not to chill the eggs—replace them, *without wiping*, in the machine, and await developments. Help at hatching time should not be too freely rendered; but, if a shell has been chipped for twenty-four hours, and the chick seems unable to kick its covering off, a little help may be beneficial. Begin at the beak, and gently remove the shell in small portions by the help of warm water, if necessary, but, should blood flow, desist at once, and replace in machine, as the blood-vessels attached to the membrane of the shell are not dried up, and the chick would probably die if removed. Our trial run having proved satisfactory, we may now proceed to business in earnest; but in order to economise space, we will examine the eggs after they have been in a few days, replacing the clear or unfertile ones with fresh. In adding fresh eggs to those in an advanced state of incubation, care must be taken that the cold eggs are not placed in contact with the warm ones. If possible, it will be advisable to thoroughly warm them through, in front of the fire or otherwise, before placing them in the machine.

*Conclusion.*—In finishing this paper, I may say it will be followed by another, in which I shall hope to make clear the testing of eggs at different stages, give instructions for making simple rearers or artificial mothers of two or three different patterns, and conclude with a few remarks on chicken rearing. I hope all who attempt to follow my instructions may be successful. I have endeavoured to make everything clear; but if not, I shall be pleased to help and advise any who may be in difficulty through "Shop." Let me impress upon each worker the necessity of quiet, regular daily attention, patience, fresh eggs, good oil, sufficient water supply, and last, but not least, cleanliness. This is ever and always an important item in the keeping and management of everything that has life, but which, unfortunately, is too often neglected.

## SHORT LESSONS IN WOOD-WORKING FOR AMATEURS.

BY B. A. BAXTER.

### The Saw.

I have, in these lessons, treated on the saw used merely to divide pieces of any size into parts, but before any real progress can be made in the more advanced use of the saw, the learner must know the difference between sawing *on* a line and sawing *up to* a line. In the first case a line may be made, and the saw not only wastes the wood on which the line is drawn, but some wood on each side of the line; but in the second case the saw is to be used so that the line is just glanced by the saw, and the whole of the wood wasted by the saw-cut must be taken from the part not wanted.

In making the various joints in which sawing forms part of the operation there is, of course, waste, and if the lines are accurately drawn, as boundary lines, clearly the saw must be made to move on the waste side of the line, outside the marked boundaries, or the finished work will be too small. Nor is this an unnecessary refinement. For instance, if a tenon is to be cut, both surfaces are generally formed by the saw, and therefore if the saw is allowed to encroach upon the tenon the fit will be materially affected.

The learner must practise with the saw until it is his obedient servant, but some advice may be given tending to that result.

The hint given to keep the eye in a plane with the cut will be slightly modified in favour of any position, differing but *little* from it, in which you can see the line.

In cases where special accuracy is needed, such as cutting shoulders to tenons, a knife-cut instead of a pencil-mark is to be recommended.

In that case, using care, the actual joint is the cut-line, rather than the sawn edge. Very little reflection will convince the worker that the whole of the wood removed by the saw must be on the waste side of the line, and that the blade of the saw should move along the line in *close* contact with it.

I am aware that the word line in this connection scarcely bears its mathematical meaning, although, even in that respect, a line made with a sharp cutting edge is much nearer the ideal line than a pencil-mark.

As to the proper saws to be used for cutting the parts of joinery, there can be no hard-and-fast rules laid down. A tenon may be so large that it may be formed by cutting with the grain with the rip saw, and across the grain with a panel saw, or so small that a dovetail saw is of ample size for both purposes. Again, a dovetail may easily be large enough to warrant the use of a tenon saw, and yet not be as large as dovetails are sometimes required.

It is of importance to learn to use the saw so as to require the aid of chisels to pare the tenons, etc., as little as possible. It is far better and economical of time to cut the work properly at first than to trust to the use of chisels to reduce tenons too stout, dovetails too big, sockets too small, or mortises too narrow.

Of course, this advice is to be applied to sawing for *joinery*; in the use of the saw as an adjunct to wood carving it is a time-saving tool, and these considerations do not apply. It may be as well, however, to add that when I speak of the saw as a tool used in wood carving, it is in the production of wrought forms from the solid in cabinet making and not to wood carving in bas-relief.

## KNOTTING, SPLICING, AND WORKING CORDAGE.

BY LANCELOT L. HASLOPE.

### SPLICING.

SHORT SPLICE—MARLINESPIKE—PRICKER—LONG SPLICE—CUT SPLICE—EYE SPLICE—CABLE SPLICE.

SPLICING is a method of joining ropes by interweaving together the strands of which they are composed. When ropes that are required to run through blocks have to be joined it is evident that knotting them together will not serve our purpose, as the knot would prevent their passing through the block. In this case splicing is always used to unite them. The splice most generally used is the short splice.

The ends of the two ropes are unlaid for a sufficient distance; they are then placed together, as shown in Fig. 112, the strands of one rope going alternately between the strands of the other. The two ropes are then jammed closely together. The end of one rope with the strands of the other rope is now held firmly in the left hand. Sometimes a lashing is put round the strands to keep them down to the rope on which they lie. Pass the middle strand, A, over the strand of the other rope, which goes down to the left of it, which is B, then bring it under C, and haul taut. Do the same to each of the other strands in succession, putting them over the next strand to them and under the next beyond. Turn the rope round and do the same to the other set of strands; this may be repeated on both ropes. Care must be taken not to bring two strands up through one interval in the rope. Each strand should come up separately between two strands of the rope they are passed into. If it is desired to taper the splice for the purpose of making it neater after the ends have been interwoven, divide the yarns of which the strands are composed, pass one-half as before, and cut off the other half. For the purpose of bringing the rope into shape again after the splice is finished, it is usual to roll it, if the rope be large, with the foot on the deck; if small cord has been used, a piece of flat wood is substituted. As the strands of a rope are tightly twisted together it requires some force to open a passage for the parts of one rope through the other. For this purpose, in the case of large ropes, a marlinespike (Fig. 113) is used. They are made of iron, copper, and hard wood. I like copper best myself, as it does not rust like iron, or break like wood. With small stuff we use a pricker (Fig. 114), which should be made of steel. Messrs. Thomas Turner & Sons, of Sheffield, make an excellent knife, with one large blade, and a good-sized pricker; the whole is nickel-plated to avoid rust. At the end of the handle is a shackle for a lanyard. It is as useful a tool as any sea-going person could desire. For very large ropes a fid is used, which is merely a wooden pin, tapered, generally made of lignum vitæ.

*Long Splice* (Fig. 115).—This is in some respects a better splice than the short splice. Unlay the ends of two ropes for a much greater distance than for a short splice and put the ends together as before. Unlay one strand (A) for some length, and fill up the space left by its removal with the opposite strand from the other rope, as B. Do the same with two more strands (C, D), C being the one unlaid, and D the one laid up in its place. Now make an overhand knot with the two remaining strands (E and F), taking care that the ends follow the lay of the rope and not across them. Divide both strands in halves and pass one-half over the next strand, and under the following one; do this two or three times and cut all the ends off close. Work the remaining two pairs of strands the same way and the splice is finished. The rope should be well stretched before the ends of the strands are cut off.

Fig. 116 is a cut splice forming an oblong loop in the middle of a rope. It is made by splicing the end of one rope into the standing part of another, as at A, A, Fig. 117, so as to form an eye of any size you wish. The end of the other rope is then spliced into the standing part of the first rope, and the spliced parts served over. A neat way of forming an eye at the end of a rope is by unlaying the strands and placing them on the standing part so as to form an eye, then put one strand under the strand next to it, and pass the next over this strand and under the second; the last strand must go through the third strand on the other side of the rope. Taper them as before by halving the strands and sticking them again. This is called an eye splice (Fig. 118).

*Cable Splice.*—Unlay the ends of the ropes to be joined for some distance, then place them together and make a short splice, leave some length, and from thence reduce each strand to a long taper by gradually cutting away as many yarns as necessary; neatly point over the taper and lay the ends in the intervals of the rope. Clap on a seizing at each end of the splice, an end seizing at the beginning of the pointing and a stop at the end of the tails. This is the best splice for cables, as it may readily be taken asunder.

Another method of making a cable splice is to splice the ends in twice each way, then to pick out the strands, worm part of them round the cable, and taper away the rest, which should be marled close down; then clap on a throat and two end seizings of ratline.

I am now approaching the termination of the subject on which I have been writing, and in two papers more I shall bring my remarks on it to a conclusion. Readers will have noticed that it divides itself into three parts, of which the first, namely knotting, was by far the longest. Splicing, which has been dealt with here, is short, but its importance must not be underrated on that account. Working Cordage now remains for our consideration, and this, as I have said, will be comprised in two papers.

## AN ARTIST'S SKETCHING EASEL.

BY A. CONWAY.

NECESSARY FEATURES — DIMENSIONS — HINGE-BLOCK—ATTACHMENT OF LEGS—SUPPORTS FOR CANVAS—ENDS OF LEGS—FASTENING EASEL AND CANVAS—HEIGHT—UTILITY.

AN easel adapted for out-of-door use or sketching purposes differs in many respects from its counterpart of the studio. Its primary qualifications should be lightness and portability, in order that it may be easily carried even, as sometimes happens, for a considerable distance to a good "subject." The conveniences for raising and lowering the canvas, adjusting it to different angles, etc., which are found in a first-class

studio easel are not expected in it; indeed, they are not necessary, as the canvases painted out of doors are seldom of large size. Therefore all that is required in the way of adjustment can be done by simpler means than are adopted in a heavy studio easel. In addition to the essentials of portability and lightness, the sketching easel must be sufficiently rigid to bear the canvas being painted.

The easel I am about to describe is of a type which, rightly or wrongly, is generally attributed to the late David Cox, whose pictures, done direct from Nature, are in such high and increasing repute. Whether he actually invented this simple form of easel or not, there is no doubt that he used it and largely popularised it among artists; and the probability is that much of his work was done on no other. I do not think that I need say any more to show that this kind of easel is thoroughly useful and serviceable, though its popularity with artists of the present day might be adduced as an additional evidence of its utility.
